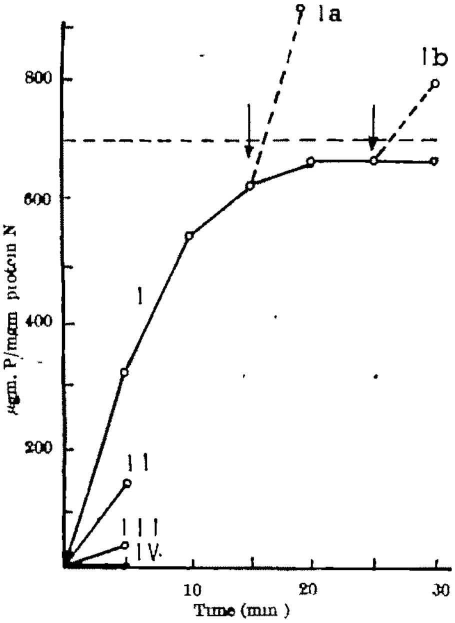
Acidification to *p*H below 4, which is known to bring about the denaturation of myosine[1], rapidly destroys the adenosinetriphosphatase activity. Most remarkable is the extreme thermolability of the adenosinetriphosphatase of muscle: the enzymatic activity shown by myosine solutions is completely lost after 10 min. exposure to 37°. This corresponds with the well-known thermolability of myosine[2]. In respect of its high thermolability adenosinetriphosphatase resembles the protein of the yellow enzyme, which when separated from its prosthetic group is also rapidly inactivated at 38° (Theorell[3]). Evidently in the intact tissue of the warm-blooded animal (all experiments were performed on rabbit muscles), some conditions must exist which stabilize the myosine against the action of temperature. A marked stabilizing effect on the adenosinetriphosphatase activity seems to be produced by the adenylic nucleotide itself. As can be seen from the accompanying graph, in the presence of adenosinetriphosphate the liberation of phosphate proceeds at 37° over a considerable period (Curves I, I*a* and I*b*), whereas the same myosine solution warmed alone to 37° for 10–15 min. shows on subsequent addition of adenosinetriphosphate an insignificant or no mineralization whatever.



Crude buffer extracts accomplish a quantitative hydrolysis of the labile phosphate groups of adenosinetriphosphate; myosine, reprecipitated three times, liberates but 50 per cent of the theoretical amount of phosphorus (see figure). It acts as true adenosine-*tri*-phosphatase and yields adenosinediphosphate, which is not further dephosphorylated and has been isolated in substance. This may serve as a convenient way of preparing adenosinediphosphate, instead of using crayfish muscle[4]. The adenosinediphosphatase is thus associated with the more soluble proteins, occupying an intermediate position between adenosinetriphosphatase and the most readily soluble phosphopherases.

Under no conditions tested could we obtain a separation of adenosinetriphosphatase from myosine. Either the activity was found in the myosine precipitate or else it was absent from the precipitates and from the remaining solution. This disappearance of the enzymatic activity we regard as the result of the start of denaturation of the very unstable myosine.

We are led to conclude that the adenosinetriphosphatase activity is to be ascribed to myosine or, at least, to a protein very closely related to and at present not distinguishable from myosine. Thus the mineralization of adenosinetriphosphate, often regarded as the primary exothermic reaction in muscle contraction, proceeds under the influence and with the direct participation of the protein considered to form the main basis of the contractile mechanism of the muscle fibre.

Trans-amination of *l*- and *d*-Amino Acids in Normal Muscle and in Malignant Tumours

As stated in a previous paper[1], glutamic aminopherase from muscle tissue is absolutely specific for amino acids of the *l*-series. Slight trans-amination effects with the artificial *d*-amino acids (optically pure) in the presence of native muscle pulp, then considered as requiring additional proof, have since been observed almost regularly in some twenty-five experiments with *d*-glutamic acid and pyruvate or with *d*-alanine, *d*-valine, *d*-leucine and *d*-isoleucine and α-ketoglutarate. The mean ratio of the trans-amination values of the optical antipodes (*l*/*d*), computed from the experiments with glutamic acid and with alanine, amounts to 7·3 (Table 1)

Table 1

Enzyme preparation	Number of expts.	Average values of transamination, % of total added amino-nitrogen		Ratio *l*/*d*
		With *l*-amino acids	With *d*-amino acids	
Muscle pulp	13	37 8	5·2	7·3
Glutamic aminopherase	7	38 1	0	∞

The study of the rates at which *l*- and *d*-amino acids are trans-aminated in the presence of malignant tissues has acquired exceptional importance in the light of the remarkable results obtained by F. Kogl and H. Erxleben[2] indicating that tumour proteins contain appreciable amounts of *d*-amino acids, and large amounts of *d*-glutamic acid in particular. A few incidental experiments bearing upon this question, reported by Euler and associates[3], are essentially qualitative and allow of no definite conclusion.

We have carried out an extensive series of experiments on the trans-amination of *d*- and *l*-amino acids in the presence of minced tissue from various experimental malignant tumours In Table 2 a summary is given of *all* our experimental results (in view of the considerable degree of variation, depending upon the very heterogeneous kind of material).

It is seen that malignant tumours completely failed to effect trans-amination in some instances, as we have found before[4]; in all other cases, the rates of amino-nitrogen transfer were markedly inferior to those observed with normal tissues (usually less than 15 per cent in 2 hours). But only the extent of trans-amination of the *l*-amino acids is lowered, while the conversion of the *d*-forms appears to proceed at the same low rate as in muscle tissue, and sometimes more rapidly (in some instances the *d*-form is not attacked at all, in other cases the *l*-form alone fails to react). On the average, there results for malignant tumours a ***relative shift*** of the configurational selectivity of glutamic aminopherase in favour of the *d*-enantiomers, owing chiefly to the lowered intensity of *l*-amino acid trans-amination. The mean ratio of trans-amination values (*l*/*d*) amounts to 1·11. The experiments are being continued.

Table 2.

Trans-amination in minced tumour tissue, 2 hours at 37°.

Type of tumour	Amino-nitrogen donator	Trans-amination values, % of total added amino-nitrogen	
		With the *l*-form	With the *d*-form
Brown-Pearce carcinoma (rabbit)	Glutamic acid	1·9	0
" " "	" "	0	0
" " "	" "	8·1	4 0
" " "	" "	2 0	0
" " "	" "	0	2 8
" " "	" "	10·8	3·4
" " "	" "	0	0
Jensen sarcoma (rat)	" "	0	7·4
" " "	" "	13 6	15·0
" " "	" "	0	14·0
Smelnikov-Krichevsky sarcoma (rat)	" "	6·2	0
Rous sarcoma (fowl)	" "	0	0
" " "	" "	3·4	9·2
" " "	" "	1·5	4·0
" " "	" "	0	0
Fischer sarcoma (fowl)	" "	20 0	0
Brown-Pearce carcinoma	Alanine	16·2	21 6
" "	Valine	16 2	8·9
" "	Leucine	20·0	12·0
Jensen sarcoma	Alanine	5·4	0
" "	"	4·1	1·2
Fischer sarcoma	"	2·1	14·0

Average with *l*-form, 6 0; with *d*-form, 5·4. Ratio *l*/*d* = 1·11

There is a certain conformity between our findings and the data of Kögl and Erxleben on partial protein racemization in tumours. But if the weak trans-amination capacity of the tumours and the relative nature of the shift in optical specificity is considered, it seems unlikely that this shift should be of fundamental significance for the genesis of the stereochemical abnormality of tumour proteins.

Reduction of the *d*-Amino-Acid Oxidase Content of Rat Tissues in Riboflavin Deficiency

It has been demonstrated that a riboflavin deficiency in the rat produces a marked derangement in those enzyme systems which are involved in the oxidation of certain intermediates of carbohydrate metabolism (Axelrod and Elvehjem, unpublished results). The possible effects of such a deficiency upon the metabolism of amino-acids have been suggested by the discovery of Warburg and Christian[1] that the prosthetic group of the *d*-amino-acid oxidase of Krebs[2] is a flavin-adenine dinucleotide.

Rats were depleted for six weeks on the *K*-12 ration described by Elvehjem, Koehn and Oleson[3]. At the end of this period, the feeding of the various supplements was begun and the rats grouped in the following manner: (1) *K*-12 basal; (2) *K*-12 plus factor *W* concentrate; (3) *K*-12 plus synthetic riboflavin; (4) *K*-12 plus riboflavin plus factor *W* concentrate fed *ad lib.*; (5) *K*-12 plus riboflavin plus factor *W* concentrate, food intake restricted to that of rats receiving only *K*-12.

The rats were fed supplements for two weeks previous to sacrifice. Twenty micrograms of riboflavin and 0·4 ml. of a factor *W* concentrate (equivalent to 0·4 gm. of liver extract) were fed daily. The factor *W* concentrate was prepared from liver extract (Wilson) by butanol extraction, the riboflavin being removed from the butanol extract by absorption on fuller's earth (Sargent) and irradiation of the filtrate in alkaline solution. The riboflavin determinations were carried out by the microbiological assay method of Snell and Strong[4]. The *d*-amino-acid oxidase was determined manometrically using an homogenized tissue suspension as the source of enzyme and *d*.l-alanine as the substrate.

The following results were obtained:

(1) The livers of rats fed *K*-12 and *K*-12 plus factor *W* concentrate showed a marked decrease in their riboflavin content. A slight decrease in the riboflavin content of the kidney was observed in both groups.

(2) The livers of rats fed only the basal *K*-12 ration contained greatly decreased amounts of *d*-amino acid oxidase The kidney showed a slight decrease.

(3) Supplementing *K*-12 with riboflavin, although restoring the riboflavin content of the liver to its normal level, raised the *d*-amino-acid oxidase content to only 50 per cent of its normal value. Complete restoration of both the riboflavin and *d*-amino-acid oxidase content of the kidney was accomplished in this group.

(4) The addition of the factor *W* concentrate to *K*-12 produced effects in the *d*-amino-acid oxidase content of the liver and kidney which were very similar to those obtained with the addition of riboflavin.

(5) The addition of riboflavin and factor *W* concentrate increased the riboflavin and the *d*-amino-acid oxidase content of both the liver and the kidney to their normal level. Similar effects were noted in the group receiving the same supplements, whose daily intake was restricted to that of the *K*-12 animals.

The results of the enzyme analyses are summarized in the accompanying table:

Q_{O_2} in Presence of *dl*-alanine as Substrate*

Group	Liver	Kidney Cortex
K-12 (6) †	0·5	17·0
K-12+*W* (7)	1·9	24·5
K-12+flavin (7)	1·7	24·1
Normal (stock) (5)	2·2	26·0
K-12+*W*+flavin, *ad lib.* (6)	2·3	25·0
K-12+*W*+flavin, restr. (5)	2·9	27·0

* Average values after subtraction of the no-substrate readings were used in the calculation of Q_{O_2}.

† Values in parentheses indicate the number of animals in each group.

These results indicate the importance of riboflavin in the synthesis of the prosthetic group of *d*-amino-acid oxidase, and that other members of the *B* complex may also be related to the formation of this enzyme.

Ball[5] has shown that xanthine oxidase is an alloxazine protein. Preliminary experiments indicate that the tissues of rats raised on the *K*-12 ration show similar decreases in their xanthine oxidase activity.

Ambisexual Action of Progesterone as Observed in the Common Australian Opossum

In contrast to the generally accepted theory that progesterone has only definite effects in females, we have found that this hormone produces readily demonstrable changes in the intact male as well as in the female Australian opossum (*Trichosurus vulpecula*).

In the immature female opossum, progesterone increases the size of the mammary glands and of the pouch. This increase may be as much as two to three times that of the pre-experimental size. In the immature male progesterone may bring on what we term testicular 'ascent', that is, the testicles which were pre-experimentally confined to the scrotum of these animals were observed to leave the scrotal sac and to ascend as far as the inguinal area. This was observed in two pouch embryos of about four months of age (body weight 0·18 kgm. and 0·2 kgm.), where after one injection of 2 mgm. of synthetic progesterone the testicles were found to have left the scrotum. A similar observation was also made in two almost fully grown male opossums of about one year of age (body weight 1·3 kgm. and 1·4 kgm.), in which broadening and relaxation of the neck of the scrotum was noted after one to two weekly injections of 2 mgm. of synthetic progesterone, and after one or two more weekly injections the testicles were found to have left the scrotum.

This ascent, however, which is made possible by a widening of the neck of the scrotum, as brought on by the administration of the progesterone, is not permanent, and on inspection the testicles may sometimes be found in front of the inguinal area or sometimes in the scrotum of the same animal. In the latter case, however, the testicles are quite easily pushed out of the scrotum under the abdominal skin. Testicles and scrotum underwent no gross atrophic changes during an experimental period lasting about two months, following which it becomes impossible to bring on testicular ascent in the almost fully grown animals because the testicles had become too large to pass through the opening provided by the scrotal neck. This is in agreement with observations made on fully grown opossums, where it was found that the neck of the scrotum was widened after the injection of progesterone but testicular ascent could not be accomplished.

The testicular ascent as produced with progesterone is entirely different from that obtained in the same species with œstrogens. In this case, the testicular ascent as brought on in immature opossums injected with œstrone or œstradiol is permanent, and the scrotum as well as the testicles undergo marked atrophic changes[1].

By continuing the weekly injections of progesterone into the almost mature animals for a period exceeding two months, a frankly androgenic reaction was obtained. The penis of these animals, which with the exception of a few days during breeding seasons is hidden in the cloaca, becomes visible and may protrude to its full length (3–4 cm.). This erection is almost permanent in the resting animal which, however, particularly on handling, is capable of retracting the organ. This observation, which indicates the androgenic nature of progesterone when administered to the intact animal, has also been demonstrated recently by Greene, Burrill and Ivy[2] following the administration of "relatively enormous quantities" to castrated male rats.

Preference of Dalmatian Dogs for Particular Positions in Coach Running, and Inheritance of this Character

Perhaps the most widely known characteristic of dogs of the Dalmatian breed is their habit of following horses and of running underneath the axles of moving carriages. Recently our attention has been directed to some observations with regard to differences in the specific positions under a carriage favoured by individual Dalmatians and the probability that these preferences are inherited.

In one large colony of Dalmatians where training for coaching has been practised for more than twenty-five years, individual animals have been permitted to choose the position beneath the carriage which he or she preferred. Some dogs consistently run with their noses very close to the heels of the horses (position *A*). Some insist on having their head just under the front axle (position *B*), while some prefer to have the head between the two axles (position *C*). Others insist upon staying underneath the rear axles (position *D*) or entirely behind the carriage (position *E*). A few animals have been so little interested in horses and carriages that their training had to be abandoned (position *F*).

Data upon the preferences of sixty-five animals have been made available to us. These have been classified in the accompanying table:

Positions	Animals preferring positions
A	12
B	34
C	2
D	4
E	12
F	1

In this it can be seen that dogs of the Dalmatian breed definitely differ with regard to the eagerness with which they follow horses and carriages. Since approximately 70 per cent of the animals tested choose those positions which entitled them to be rated as 'good' coaching dogs, it is evident that this trait is deeply entrenched in the breed.

We have also grouped these individuals according to their family relationships. Such classification shows that among the descendants of parents having a 'good' rating similar ratings predominated. On the other hand, matings of a strain headed by a champion Dalmatian who was 'poor' at following a coach gave descendants who also were 'poor' through three generations.

Thus it appears (1) that the tendency of Dalmatians to follow horses and carriages falls into several different grades and (2) that these gradations may be transmitted to descendants. It is planned to publish our data and their analysis in detail later. Meanwhile, since training of Dalmatians for running with carriages has nearly disappeared in America, we appeal to readers of NATURE who have observations upon the responses of Dalmatians to training for coaching to communicate with us.

Oligodynamic Control of Eelworm (*Heterodera marioni*)

FURTHER researches relative to Nägeli's discovery (1893) of the oligodynamic action of various metal ions revealed that the silver ion in strongly diluted solutions (0·9–0·01 mgm. silver per litre) possesses high germicidal properties.

Various countries are already applying this principle to the sterilization of preserves, drinking water and swimming baths as well as for medical purposes.

Even small animal beings, the size of fish larvæ, etc., are exterminated by these solutions, whereas higher organisms are not detrimentally affected.

At the Tobacco Research Station, Trelawney (Southern Rhodesia), these data were made a starting point for an entirely new method of practical eelworm control as against the 'classical' chemical and agricultural methods, which hitherto have not succeeded in solving the problem.

The first tests were made *in vitro* with a solution of silver nitrate (1 mgm. per litre). From one to three quarters of an hour was sufficient to kill all larvæ. In the tobacco plant no harmful influence could be detected with solutions weaker than 1 : 10,000. The practical application, however, presented some difficulties: (*a*) because of the photosensitive property of silver salts, rapidly rendering the solutions inactive to a large extent; (*b*) because of the strong affinity of silver ions as regards organic matter adsorbing the silver. These difficulties could be overcome by the application of soluble, organic silver compounds. In a field experiment the best results were obtained with *silver proteinate*. Of the plants treated only 7 per cent ($= B$) were infested as compared with $B = 90$ per cent in the controls. Moreover, the average degree of infestation ($= A$) of the diseased, treated plants was less than 5 per cent, while A constituted 26 per cent in the controls. This gives us the following relative figures: $\frac{A \times B}{100} =$ 0·36 in the plants treated as against $\frac{A \times B}{100} = 23$ in the controls, that is ± 1 : 64. Only 500 gm. silver proteinate per acre (± 0·1 gm. per plant) was used at a cost of 21*s*. per acre. The silver proteinate was mixed with the fertilizer and applied in standard cups. As the controls had not reached 100 per cent and the outlay allowed for a larger dose per acre, hothouse tests were afterwards made with 0·3 gm. per plant (about 3 metric pounds per acre). This gave the required 100 per cent control.

Further research is in progress to determine the minimum quantity of silver proteinate with optimal effect, the action on the latent stages (for example, the ova) and the application of silver proteinate to the disinfection of river water, utilized for watering seed-beds, as well as the action of other, possibly preferable, silver compounds.

Propagation of the Agent of Measles in the Fertile Hen's Egg

IN the several reports in the literature concerning attempts to propagate the agent of measles in the fertile hen's egg, data on the demonstration of the agent by experimental inoculation into those species which are generally regarded as susceptible, namely, humans and monkeys, have been lacking or inconclusive.

In the course of experiments on measles, we have initiated several independent sets of serial egg transfers with Seitz filtrates of throat washings (obtained through the courtesy of Dr. Joseph Stokes, jun., and Dr. Aims C. McGuiness of the Children's Hospital, Philadelphia) collected in broth from different measles patients on first appearance of the rash. Despite the fact that lesions in the chorioallantois or viscera of the embryo were not regularly observed, pooled broth emulsions of these tissues have been passed from egg to egg by the method of Burnet[1], and rhesus monkeys have been inoculated in order to detect the presence of virus. With the first strain after four such egg transfers, and with two other strains (each initiated with washings from different patients) after five egg passages, the monkeys inoculated with embryonic material showed after variable inoculation periods coryza, malaise and a typical maculo-papular rash[2] with subsequent branny desquamation. Two of the monkeys also showed a definite neutrophilopenia.

A characteristic maculo-papular rash without other accompanying symptoms was observed in a monkey on the 12th–16th days after infection with 12th egg passage material of one strain and on the 10th–11th days in a monkey given 29th egg passage material of another strain initiated by unfiltered human measles blood. Two monkeys inoculated with material from normal eggs showed no symptoms other than some neutrophilopenia and, like normal animals, developed the typical disease of experimental measles when both groups were tested with active virus from human cases. Two monkeys previously recovered from infection with 4th or 5th measles egg passage material respectively, when retested at the same time as the above normals and those previously given normal egg material, remained perfectly normal.

We are investigating whether the milder syndrome produced in monkeys with later egg passages is due to modification or disappearance of the agent of measles.

In association with Dr. Joseph Stokes, jun., and Dr. Gerald O'Neill of the Children's Hospital, Philadelphia, a study is being made of the effects produced in several groups of children by inoculation with egg passage material.

Names of some Atlantic Loggerhead Turtles

Mr. H. W. Parker in commenting upon my letter to Nature[1] disagreed with my opinion that the turtle Schöepff[2] had figured as *Testudo caretta* Linn. was the olive-backed Mexican loggerhead and not the common brown-red form.

My reasons for this opinion are that I have not come across any brown-red loggerheads with four enlarged inframarginal scutes, whereas de Sola[3] figures an undoubted Mexican olive-backed loggerhead showing exactly the reverse arrangement of inframarginals to Schöepff's figure, namely three on the right and four on the left. There is no doubt that de Sola's photograph depicts the Mexican form, since it possesses only a single enlarged mandibular scale on each side, as does Schöepff's figure, whereas the brown-red loggerhead generally possesses three, sometimes two[4]. It will also be noticed that Schöepff's other figure, a carapace in dorsal view, possesses the subcircular outline characteristic of the Mexican, whereas the carapace of the brown-red form possesses a relatively compressed pygal area[5].

I consider this evidence sufficient for regarding Schöepff's figure a representation of the Mexican loggerhead. Parker[1] has already explained that Linné's description of *Testudo caretta* is too vague for specific identification, consequently this name should be available for the first recognizable specific account of a loggerhead described as *Testudo caretta*. The first to do so was Schöepff[2], who figures the Mexican olive-backed loggerhead. I agree with Parker[1] that Daudin's name *Testudo caouana*[6] is inapplicable to this turtle, but he gives a good reason for applying it to the brown-red loggerhead of the Atlantic.

P. Deraniyagala.

Colombo Museum,
Ceylon.

[5] Hay, *Proc. U.S. Nat. Mus.*, 34, 183 (1908).

[6] Daudin, *Hist. Nat. Rept.*, 2, 54 (1802).

There appears to be no authority for the belief that, where the original description is unrecognizable, the name is applied on the basis of the first recognizable account which appears afterwards under the same name. If the work of subsequent authors is taken into account at all, that of Lacépède, Bonnaterre and Daudin must also be considered. They proposed the specific name *caouana* as a substitute for the Linnean *caretta* and in doing so might be considered to have fixed the Linnean name.

Training of Engineers

The reference to the training of engineers which appeared in the issue of Nature of July 29, p. 218, is of special interest at the present time in view of the forthcoming conference convened by the Institution of Civil Engineers for February 1940, and of the grave shortage of engineers, not only in Great Britain, but also in the Dominions. The remark made in the latter part of the article on the perfunctory interest shown by the governing bodies of our engineering institutions in this question can be fully endorsed from long personal experience. Thus the Institution of Municipal and County Engineers examines many hundreds of candidates yearly, but remains solely an examining body, and offers no official assistance to those candidates who are not in a position to go to a university or recognized technical college for their training, and this applies also to the Institution of Civil Engineers itself.

The only way in which such candidates can obtain their technical training is either by private study, a most difficult task at best, or by means of a correspondence course, and I have been unable to find a single engineering college in Great Britain catering for such men which possesses any backing of a statutory nature such as is possessed by universities and technical colleges. In other words, candidates of this category are forced to obtain their technical training by means of a correspondence course organized by a 'college' trading solely for private profit. Many of these establishments are no doubt efficient enough as regards the getting of candidates through examinations, but this does not necessarily produce well-trained engineers, and up to the present there has been no provision whatsoever in Great Britain for correspondence courses organized by authorities financed by public funds.

In the Union of South Africa, such provision is made by the Witwatersrand Technical College, with the special object of reaching those men who by reason of position or the location of their work are unable to obtain their technical training at a university or technical college, and similar provision is made in certain respects by the University of Melbourne, Australia. In my opinion, the immediate need is the inclusion on education committees of engineers who are really interested in the training of this class of man, and the active co-operation of education authorities with the view of meeting their need by the provision of adequate correspondence courses entirely divorced from considerations of private profit.

Bernard H. Knight.

University of the Witwatersrand,
Johannesburg.

Dr. B. H. Knight's letter is welcome as emphasizing the apathy which exists on this subject. What has been done in South Africa and also in Australia for students out of reach of teaching institutions should be possible in England. The aspect of private profit is a bogy that obsesses the professional educationist, but the fact that the practical training of engineers is far more influenced by commercial considerations causes no concern whatever. While it is the case that correspondence colleges in Great Britain have no official recognition, it can be said that at least one, the Technological Institute, has received the encouragement of both the Institution of Civil Engineers and the Royal Aeronautical Society.

What has to be feared is the 'dead hand' of officialdom, as is shown by the following case. A lad working in the country received an elementary training in classes held in the works and then went to a technical institute in the near-by town. Having there completed the equivalent of the first two years of the National Certificate course, he took the third-year subjects in the county borough, 10–12 miles away, travelling three nights a week, and passed the examination. He was not, however, awarded the certificate. The verdict was that he must now attend the second-year course—in effect, a sentence of one year's educational imprisonment. While the system is controlled with such lack of vision that a better way out could not be seen, any prospect of an enlightened policy must be dim, but it is to be hoped that the forthcoming conference will deal fairly with the case of those hapless students who are, as it were, 'without the gate'.

THE WRITER OF THE ARTICLE.

Points from Foregoing Letters

USEFUL results can be obtained by submitting built-up molecular films to high vacuum; S. J. Gregg and E. E. Widdowson have determined by this method the condensation coefficients of stearic and arachidic acids, and the free-acid content of built-up films of barium soaps.

K. S. Krishnan and N. Ganguli find that the specific resistance of a single crystal of graphite in the basal plane is at least one ten-thousandth of that along the plane normal to the basal plane.

Using the assumption that a heavy electron may be regarded as a quasi-stable state of an ordinary electron, Ira M. Freeman derives a formula for the life-time of a mesotron which gives a result in good accord with experimental deductions.

H. O. Jenkins has found a linear relation between dipole moment and $1/r^2$, in the series C_6H_6, $C_6H_5CH_3$, $C_6H_5C_2H_5$, etc., where r is the distance between the carbon of the ring and the terminal carbon atom of the side chain (H in the case of C_6H_6). This relation also gives the correct limiting value of μ for the series.

P. K. van der Merwe describes a simple and inexpensive method of decontaminating water of its fluoride by the addition of superphosphate and precipitating tricalcium phosphate by the addition of lime.

W. A. Engelhardt and M. N. Ljubimowa state that they have extracted adenosinetriphosphatase of muscle. It is precipitated with and has all the properties of myosine. Thus the primary energy-yielding reaction in muscle, the hydrolysis of adenosinetriphosphate, seems to be associated with the protein forming the anisotropic contractile part of the muscle fibre.

In an extensive series of experiments. A. E. Braunstein and R. M. Azarkh have shown that transamination of *d*- and *l*-amino-acids is either not effected at all by minced tissue from various malignant tissues or at a much lower degree than it is by normal tissues.

A. E. Axelrod, H. A. Sober, and C. A. Elvehjem have demonstrated a decrease in the *d*-amino-acid oxidase content of liver from rats fed on a diet low in both riboflavin and factor *W*. When the basal ration was supplemented with riboflavin alone or a factor *W* concentrate alone, there was some increase in the oxidase content of the liver, but the value returned to normal only when both riboflavin and the factor *W* concentrate were given.

Ambisexual action of progesterone has been observed by A. Bolliger and A. Carrodus in the common Australian opossum. In the female, progesterone was found to increase the size of the pouch; in the male, broadening of the neck of the scrotum was observed, followed in immature specimens by testicular ascent. After prolonged administration the penis remained in a state of erection.

H. C. Trimble and C. E. Keeler report that over a period of twenty-five years Dalmatian dogs inhabiting a large colony have shown differences in the eagerness with which they have followed horses and have had individual preferences for particular positions when running beneath a carriage. These differences and preferences appear to have been transmitted to offspring through several generations to an extent which seems to have genetic significance.

J. W. H. Horry describes a new method of practical eelworm control by the use of soluble, organic silver compounds. The best results were obtained with silver proteinate.

Filtrates of throat washings collected from measles patients on first appearance of the characteristic rash have been used by G. Rake and M. F. Shaffer to infect fertile hens' eggs. Broth emulsions from such infected embryonic tissue have been passed from egg to egg, and even after five such transfers are still able to produce measles symptoms in rhesus monkeys.

Referring to an article in NATURE on the training of engineers B. H. Knight endorses, from personal experience, the statement made as to the perfunctory interest shown by the professional institutions in education. For those out of reach of approved colleges he recommends the establishment of correspondence courses as have been arranged in South Africa and Australia. Our contributor, by way of comment, directs attention to the way in which the approving authority at present deals with cases not conforming to the system, and to the need for a more enlightened attitude towards such students as are hampered by distance.

RESEARCH ITEMS

Ancient Metal Objects

The Research Committee of the British Association engaged in the analysis of ancient metallic objects and their comparison with naturally occurring ores (formerly the Sumerian Committee) prepared a report for the Dundee meeting on its work in 1938–39. The method of micro-analysis has been mainly employed, but recently time and cost have been saved by quantitative determinations by means of the spectrograph. Standard alloys of known composition make it possible to give actual figures, in place of approximations, of an accuracy approaching that of chemical analysis. A further twenty-five specimens from Troy (Prof. Blegen) have been examined, and a large number remains which will be examined spectroscopically. Broadly speaking, the specimens from Troy I–IV are of copper, mostly with high arsenic, but including two bronzes, while from Troy VI and VII bronzes greatly preponderate, and the proportion of arsenic is less, indicating a different source for the copper. Analyses of ores from many of the possible sources of copper are still lacking. Fifteen knives and spears from Cyprus (J. R. Stewart) included only one bronze, which contained several per cent of zinc, as did one of the specimens free from tin. Arsenic and silver were prominent impurities. Nine objects from Tell Duweir were: gold, three; electrum, one; copper, three; and bronze with varying impurities, two. Eleven objects from Hureidha, south Arabia (Miss G. Caton-Thompson) were: copper, six; bronze, three; iron and silver, one each. An axe-hammer from Hungary (H. J. E. Peake) was of native copper. Two fragments of pottery with black glaze (Mr. Peake), one Tell Halaf ware from Arpachiyah, and the other al'Ubaid ware from Nineveh, showed the pigment in both instances to be magnetic oxide of iron.

Kiliwa Indians of Lower California

Visits on three occasions between 1928 and 1936 paid by Peveril Meigs, 3rd. to the group of Indians in Lower California known by variants of the name Kiliwa in the records of several writers, have added to the records of a people of whom in 1929 only thirty-six individuals, mostly members of five families, were still living (*Ibero-Americana*, 15; 1939). The Kiliwa territory covered an area of some 1,500 sq. miles, with a diversity of natural landscape. The principal inhabited part was a semi-arid area lying between two great forested plateaux. In the southern part of Kiliwa territory is the San Felipe Valley, a wide alluvial floored structural basin some 1,500 ft. above sea-level. The only part occupied to-day is the Arroyo Leon Upland, a rough granitic upland with an elevation of 3,000 ft. The existence of an early population is indicated by rock-carvings or petroglyphs. The Indians have no legends to explain by whom they were made. Descent is reckoned patrilineally, and the sibs or lineages are definitely associated in the minds of the people with specific geographic localities. A taboo on mentioning names of the dead made it difficult to obtain information about the lineages. The principal movements of the Kiliwa consisted of their annual treks to the piñon groves and to San Felipe for food. Feuds with neighbouring tribes restricted travel. Certain foods were outstanding, at the head of the list being the agave, or mescal, plant, cooked by the usual roasting pit method of the south-west. Rabbit and deer were probably the most important meat animals, and were hunted with throwing sticks or bows and arrows. Large-scale slaughter took place in co-operative hunting, when the game was scared by bush-fires lit by the hunters.

New Breeding Place of Gannet

For so many centuries the gannet remained restricted to a few nesting sites that any fresh evidence of the remarkable extension of range now taking place is of unusual interest. In July 1939, the Rev. J. M. McWilliam and Lord David Stuart saw three or four gannets on the Scar Rocks in Luce Bay, Wigtownshire; and on a subsequent visit on August 1 they found a nest containing a young gannet. The Scar Rocks are only about a hundred yards in length and about fifty feet high, but the south-east end is precipitous, and there the birds could nest in security. It is possible, therefore, that the nest of 1939 indicates the beginning of a new colony (*British Birds*, 33, 105, Sept. 1939). We would add that the successful nesting of this small number of gannets lends no support to the suggestion recently made upon rather slender evidence that successful nesting in a new colony is associated with a stimulus due to the group reactions of a considerable number of birds.

The Four-Eyed Blenny

The suggestion that the horizontally divided eye of Anableps is related to the double function of vision in air and in water, led C. M. Breder and E. B. Gresser to study the four-eyed blenny, *Dialommus fuscus* (*Zoologia*, 24, 239; 1939). The specimens examined were obtained at Indefatigable Island, Galapagos. In outward appearance each eye seems to have two pupils, but this is due to the presence of a vertical band of pigment in the cornea, and the internal structure of the eye, with its single lens, is like that of typical fishes. The purpose of the pigment band is unknown, though it obviously makes vision possible only through a fore and an aft opening. But since the focus of the eye of a fish is altered by back and forward movements of the lens, it is just possible that the four-eyed blenny might be able so to adjust the lens that the anterior portion was in focus for aerial vision while the posterior portion was in focus for vision in water. This suggestion could hold only if the fish was in a vertical position, and it has been observed that a habit of the blenny is to climb out of steep-sided pools by scaling the vertical walls of rock. Clearly a decision about the function of this curious eye arrangement must await further observation and experiments in an aquarium.

Adaptation in a Dolphin's Backbone

In his very thorough description of the skeleton of *Prodelphinus graffmani*, a species which he himself first described in 1934, Einar Lönnberg directs attention to the varying stability of the backbone in its different regions (*Ark. Zool.*, 30, No. 20; 1939). From the arrangement of the articulations of the vertebral elements and the angle of the spinous processes it would appear that the anterior three fifths of the backbone has almost no power of bending in a dorsal direction up to the 32nd vertebra. From that point to the 40th vertebra, in the lumbar region, vertical mobility has been gained by modifications in the articulations. Then follows a second less movable area, in the proximal part of the caudal region, which is succeeded by the terminal half of the tail region which is capable of strong movements in any direction. The total number of vertebræ in the specimen examined was 77.

Blowfly Research in Australia

The sheep blowfly problem is well known to be one of major importance in Australia. A considerable amount of valuable research has been carried out by the staff of the Federal Council for Scientific and Industrial Research. These investigations come under two main categories, namely, the collection of information on these insects and their relation to their environment, and the study of the susceptibility of sheep to blowfly strike. An essential requirement for much of this work is a large and regular supply of blowfly larvæ. This in turn involved the development of a simple synthetic medium as the food supply for the larvæ. The Council's Pamphlet No. 90, 1939, by F. G. Lennox, is entitled "The Development of a Synthetic Medium for Aseptic Cultivation of Larvæ of *Lucilia cuprina*". The basal medium contains only yeast and sodium chloride, in addition to agar, which is added to give a suitable gel consistency. While the larvæ attain their full size on this medium, their growth is more rapid on one in which the agar is replaced by fresh egg-white. The production of fully grown blowfly larvæ on a yeast medium has, it seems, rather upset preconceived ideas as to their supposed nutritional requirements. The author states that he knows of no previous record of the successful rearing of "flesh-fly larvæ" in the total absence of animal protein.

Genetics of Streptocarpus

W. J. C. Lawrence, R. Scott-Moncrieff and V. C. Sturgess (*J. Gen.*, 38, 299–306; 1939) make an interesting comparison between the history, the genetics and chemistry of plant pigments in the genus Streptocarpus. The acaulescent group of species differ in morphology and geographical distribution from the caulescent group. The former group has 32 chromosomes and the latter group has 30 chromosomes. All the species contain anthocyanins derived from delphinidin, except *S. Dunnii* which contains cyanidin. In 1886 *S. Dunnii* flowered (brick red) at Kew and was hybridized with the species of the blue and ivory series. From these crosses called × *kewensis* and × *Watsoni*, new colours combining the red of *Dunnii* with the blue-flowered species were obtained. The genetics of garden hybrids agree with this historical account. Gene *A* is necessary for anthocyanin formation and alone gives salmon colour (pelargonidin derivatives). *RA* produces (rose) anthocyanins derived from cyanidin while *AO* gives (mauve) anthocyanins derived from delphinidin, *AD* (blue) produces the 3–5 dimonoside of pelargonidin in place of pentoseglycoside-dimonoside. *ARD* should and does give magenta (peonidin + cyanidin 3–5 dimonoside). *AR* is derived from *S. Dunnii* and *O* and *D* from the remaining species (for example, *S. Rexii*).

Genetics of Blackarm Resistance in Cotton

Bacterium malvacearum causes serious damage to Sakel cotton in the Sudan. R. L. Knight and T. W. Clouston (*J. Genetics*, 38, 133–160; 1939) have artificially infected Sakel cotton and hybrids with other strains. The authors have clearly shown that two factors B_1 B_2 control resistance. Sakel cotton has the constitution $b_1b_1b_2b_2$. In the authors' grading of twelve classes of susceptibility, different genotypes give characteristic and definite results. B_1 is dominant and confers "10·1" resistance on Sakel cotton, which is normally "12", while B_2 confers "7" resistance. Together B_1B_2 give grade "5". More resistance is given to the variety Uganda B31 by B_1 and B_2 than to Sakel and it is shown that this is due to a difference in modifying factors.

Peneplanation of South Africa

In a very detailed paper on "Some Observations in the Physiographical Development of Central and Southern Africa" (*Trans. Geol. Soc. South Africa*, 41; 1938), F. Dixey contends that the erosion of southern Africa did not advance steadily from early Jurassic until Tertiary times with the production of one great peneplain. He believes that the evidence he adduces points to two main stages each followed by a minor stage that was effective only in the softer formations and around the coasts. Furthermore, he suggests that in Cretaceous times there was a prolonged depression to the extent of several thousand feet, and that the uplift of late Tertiary and post Tertiary times did little more than restore southern Africa to its early Cretaceous level. He thinks that the Cretaceous transgression of the sea was due not to depression of the land but to a gradual rise in the level of the sea which was possibly due to continental drift changing the shapes of the ocean basins. On this interpretation, after the great late-Jurassic uplift, any continued slow elevation was more than counterbalanced by the rise in sea-level that caused a flooding of the coastal peneplain and the lower courses of the larger rivers. As the rise in sea-level waned in early Tertiary times, the continental uplift gained a slight lead, with the result that the Eocene and uppermost Mesozoic sediments were base levelled with the older rocks.

Melting of Granodiorite by Andesite

E. S. Larsen and G. Switzer describe (*Amer. J. Sci.*, August 1939) an obsidian-like rock that has been formed from the natural melting of granodiorite. The granodiorite occurs as an inclusion about 50 ft. long and 40 ft. wide in a Tertiary volcanic plug of andesite near Carlsbad, San Diego County, California. The product of melting looks very like a porphyritic obsidian. The glass is rhyolitic in composition, but contains 4·57 per cent of water. The addition of water was apparently necessary to bring about the fusion. The crystals that remained unmelted are about those which normally occur as phenocrysts in a groundmass such as this rhyolitic glass. The alkali felspar is completely resorbed, but some quartz remains. Biotite and hornblende, in spite of the high water content, have been changed to augite. The melting of an igneous rock, supplied with the appropriate mineralizers, should follow the reverse course of that of crystallization. The early material to become liquid should be the same as the late material to crystallize. The composition of the glass shows that this is true for the inclusion under discussion. The lack of any inversion of quartz to tridymite indicates that the temperature of melting was below 870° C.

Helium Ratios of Igneous Rocks

In an effort to extend the scope of geological age measurements based on the accumulation of helium in igneous rocks, researches were initiated at the Massachusetts Institute of Technology which have revealed serious errors in previously published results. Co-operative investigations undertaken by Evans, Goodman, Keevil, Lane and Urry (*Phys. Rev.*, May 15, 1939) show that the radium determinations on which the previous helium time-scale was based are incorrect by a factor of more than two. The magnitude of the downward revision of ages varies according to the thorium-uranium ratio of the individual specimens. The new age determinations have been made by two entirely different techniques, the alpha-helium method and the radon-thorium-helium method. The former is independent of radioactive standards and its results are in agreement with the new measurements by the radon-thorium-helium method. Precision radium standards in the region of 10^{-12} gram have been verified. These researches represent the first comparison of helium age-measurements on the same specimens by two or more observers. While the ages of many individual geological horizons are lowered by these new results, the total span of geological time remains unreduced. A Pre-Cambrian norite from the Stillwater Complex gives a helium age of 1850 ± 300 million years by the alpha-helium method and 1800 ± 200 million years by the radon-thorium-helium method. The reason for the remarkable discrepancies between helium ratios and lead ratios at lower ages remains unknown.

Volcano-seismic Activity at Montserrat (1933–1937)

Complementary to the publications of the 1936 Royal Society expedition to Montserrat there has now appeared a monograph by Frank A. Perret, the well-known volcanologist ("The Volcano–Seismic Crisis at Montserrat 1933–1937", Carnegie Institution of Washington Publication, No. 512; 1939). Montserrat is known to be one of a long chain of islands of volcanic origin, being really a mountain standing half drowned in the sea. Each of the mountain islands of the chain is thought to be connected by a common fissure system to a single parent magma. The surface sub-volcanic phenomena in the 1933–1937 period consisted of abnormal activity in pre-existing soufrières, being chiefly confined to the chemical intensity of the exhalations. In addition to the usual sulphurous and sulphuretted hydrogen emanations, there appeared a dangerous higher sulphide of hydrogen, probably the persulphide, which caused Mr. Perret considerable trouble and necessitated his taking medical treatment. Perret's hypothesis is that the whole of the geophysical phenomena were due to the efforts of the magma to re-establish old vents in supposedly extinct volcanoes and that much may be made of a conception of a "gas-sheeted magma in horizontal subterranean fissures" two of which were distinguishable in the region. The soufrières of Montserrat are considered as having been caused mainly by the penetration of meteoric water to a subterrain of sulphided limestone that had been reheated intensively by uprising magma. A time chart showing soufrière activity, earthquake activity, and the possible "lunisolar influences" has been drawn up. We are pleased to note the mention by Mr. Perret that the scientific work initiated on the island is being continued by local effort.

Cosmic Rays at High Altitude

T. H. Johnson and J. G. Barry (*Phys. Rev.*, 56, 219; 1939) have investigated the distribution in direction of the cosmic rays near the top of the atmosphere. The apparatus was carried by small balloons and radio signals were transmitted corresponding to the passage of a single ray through a system of counter tubes arranged at an angle of 30° to the horizon. As the balloons rotated slowly about the vertical, the azimuth was signalled to the ground station by an arrangement including a photocell on which the sun's rays fell. The experiments were made in equatorial latitudes. It is well known that the cosmic rays at sea-level show an asymmetry between east and west directions which at the equator amounts to several per cent. This asymmetry is ascribed to the hard component of the rays, and shows that the primary particles responsible for the hard rays are deflected in the earth's magnetic field and possess predominantly positive charges. No asymmetry was observed at the top of the atmosphere, so it appears that the incoming particles which give rise to the 'soft' radiation predominant at high altitude have positive and negative charges in equal numbers. It follows that these 'soft' particles, which are presumably electrons and positrons, cannot be the primaries for the 'hard' cosmic rays at sea-level, and the authors suggest that these primaries are probably protons.

Solar-Terrestrial Relationships

The fifth report of the International Commission for the Study of Solar-Terrestrial Relationships (Firenze: Tipografia Barbera) contains summaries relating to the present state of knowledge in this direction and to the results of recent collective and individual research. The subject matter falls under seven general headings: (1) researches in terrestrial magnetism; (2) solar phenomena; (3) propagation of wireless waves and phenomena of the ionosphere; (4) polar auroras; (5) the earth's upper atmosphere; (6) cosmic radiation; (7) meteorological phenomena. A number of contributions deal with the various aspects of the recently recognized relationship existing between bright eruptions in the sun's chromosphere and sudden disturbances in the ionosphere (ionospheric irruptions) which are especially evident in the *D*-layer at a height of 100 km. It is pointed out that the study of the effects of bright solar eruptions on the ionosphere does not support the ultra-violet theory of magnetic storms. Advances in geomagnetism have been made, but the precise location of the electric current-systems to which magnetic storms can be attributed cannot yet be inferred with certainty from observations of the magnetic changes at ground-level. Among the summarized results of investigations between solar and meteorological phenomena (1936–38) is stated the conclusion that no clear case has yet been shown for a close and persistent correlation between the variations of the levels of the great lakes and the sunspot cycle. Hitherto, the apparent correlation found between these phenomena has been considered one of the most promising in solar-meteorological relationships.

TRANS-ATLANTIC AIR SERVICES*

THE problem of trans-Atlantic flight has been viewed so often from a false angle as "so much nonsense has been talked and written" about it, that the technical aspects of the case were seldom appreciated.

With regard to the merits of the alternative routes, it must be remembered that the one offering the shortest stages, that is, technically the easiest, is not the most suitable commercially, as it would not be operable in winter. Also it is necessary to remember that bases in Canada for Empire air communications, and in the United States for the traffic between New York and Europe, must be used even though they do not lend themselves for the most suitable subdivision of the flight into stages. Further, the conditions at these and the English ends of route may impose a limitation upon the choice of type of machine, landplane or seaplane, that again may not be technically the most suitable for the flight itself. The route with the shortest stages, the most economical to operate, would be Southampton–Horta (Azores)–Botwood–Montreal or New York, but this is difficult because of lack of landing facilities at the Azores. The difficulties on each of the alternative routes suggest that the ultimate aim will have to be a direct flight from England (at present Southampton) to New York or Montreal. This presents many formidable technical difficulties to the aircraft designer, particularly with regard to strong winds and icing conditions during the winter. What would appear to be the easiest solution, by dividing the flight into stages of most suitable length by floating islands or seadromes, is considered to be impracticable.

With regard to the nature of the services provided, Major Mayo is of opinion that, owing to the short duration of the passage, there is no need to offer comfort comparable with a modern liner. A fast and frequent service of comparatively small aircraft would appear to be ideal. It should be possible to attain a daily overnight mail service between London and Montreal or New York. The difference between the conveyance of passengers and mail is very real, and points to the necessity of separating the two types of traffic. A passenger with reasonable luggage and the necessary equipment and furnishing for his comfort demands about 500 lb. weight. Mail, with a limit of half an ounce per letter, would give an equivalent of 20,000 letters, which would occupy much less space. Therefore a mail plane, being small, can be built in quantities to operate at high speed and high frequency, while the passenger machine must be larger, slower, and less frequent.

The time to be taken for the journey is affected by the prevailing wind of an average forty miles an hour against the west-going crossing, but the gain in time in travelling west is in favour of it. Surprisingly, the latter more than balances the former. The optimum transport conditions, to avoid bunching up of machines at one end, and the consequent uneconomical return of some of them, would be equal scheduled times for either way of crossing; but this would occur at a cruising speed of 156 miles an hour, which Major Mayo suggests is much too low for other aspects of the problem. He considers a speed of 300 miles an hour to be practicable, which would allow a letter posted in New York at 5 p.m. to be delivered in London at 12.30 p.m. the next day, and one posted in London at 8 p.m. to be in New York by 8 a.m. the following morning. The slower passenger machine could have a speed of 200 miles an hour, making the time of the average journey 21·3 hours, a not unreasonable figure for a passenger to endure physically, and a considerable gain on any other forms of transport.

The speed of the aircraft is governed, among other things, by the wing loading, and while the maximum for this type of craft is about 33 lb. per sq. foot at present, the author considers that a figure of 50 lb. should be possible with present-day refinements in design. Forecasts point to the ideal machine to this specification being a land plane of 60,000–70,000 lb. total weight. It is not considered to be any further risk to fly a land plane over water, as even the largest flying boat would not keep afloat for any considerable time in average Atlantic conditions in the event of a forced landing. The greatest difficulty with high wing loading is that of 'taking off' with maximum load, and Major Mayo then discusses the methods of dealing with this problem. There are three of these in use to-day, catapulting, refuelling in the air after taking off more lightly loaded, and a composite aircraft in which the long-distance craft is in effect taken up into the air on the top of another one and launched at a higher speed than that at which it could have left the ground with safety. He considers that the latter method is the most promising.

With regard to stratosphere flying, so far as can be foreseen, cruising speed can be increased by about 1·5 miles an hour per 1,000 feet of altitude. Meteorologists estimate that the prevailing westerly winds over the Atlantic increase at about 2 miles an hour per 1,000 feet of altitude, so that for the east to west crossing stratosphere flying would actually reduce the net speed.

* Abstract of a paper read before Section G (Engineering) of the British Association at Dundee on September 1 by Major R. H. Mayo.

PUBLIC HEALTH IN GREAT BRITAIN

THE twentieth annual report of the Ministry of Health dealing with the year 1938–39, published on September 14*, covers the whole range of the Ministry's work, including finance, public health, public assistance, housing, national health insurance, pensions, and—for the first time—certain aspects of civil defence. A report on the Welsh Board of Health is included.

In presenting his report, the Minister of Health, Mr. Walter Elliot, remarks that in spite of the strain of the present emergency, it has been possible to

* Cmd. 6089. H.M. Stationery Office. 5s. net.

maintain and develop the normal work of the Ministry, and that the main indexes of progress in health and public welfare during 1938 show no faltering in the upward tendency of every recent year.

Compared with the previous year, the standardized death-rate fell by 0·8 to 8·5 per 1,000 population. This is the lowest figure on record, and compares with a rate of about 12 twenty years ago. Infantile mortality fell by five points from the 1937 figure to a new low record of 53 per 1,000 live births. That most regrettable form of death, maternal mortality, fell for the first time below 3 (2·97) per 1,000 total births. The slight upward trend in the birth-rate, which first became apparent after the low record of 14·4 in 1933, carried the figure for 1938 to 15·1 per 1,000 population, though the latter figure is still below that of every year before 1933. Deaths from tuberculosis, numbering 26,176, were actually fewer by 2,353 than in 1937, the biggest fall in one year since 1934. The anti-tuberculosis service of local authorities, together with better general hygiene and housing, sanitary environment and protection of the milk supply, appear to be exerting a continuous and satisfactory effect in the reduction of this disease.

On the other hand, cancer mortality still gives cause for anxiety, for the total number of deaths attributable to cancer in 1938 is estimated provisionally at 68,600 as compared with 66,991 in the previous year. Cancer deaths, in fact, have been steadily increasing in every year, from 27,487 in 1901 to the present time. Cancer is, however, a disease to which young persons are less susceptible than the middle-aged or old, and it is common knowledge that the young are becoming proportionately less numerous in the population, and the increase in cancer mortality in recent years may, therefore, be more apparent than real. A disturbing factor is that investigations pursued by the Ministry show that, in spite of recent developments in cancer treatment, a large proportion of sufferers who could benefit from treatment, if it were given sufficiently early, either do not receive treatment at all, or receive it under unsatisfactory conditions or at so late a stage in the disease that cure, or even temporary relief, is impracticable. There is, moreover, a deficiency of accommodation at hospitals possessing adequate facilities for all forms of treatment. It is to be hoped that a new Cancer Act, passed in March last, may remedy this unfortunate position.

Of the infectious diseases, the number of notified cases of the enteric fevers decreased from 2,149 in 1937 to 1,322 in 1938, and the deaths from 206 to 163, the lowest ever recorded, except for 1934. Notified cases of pneumonia were considerably less than in the previous year, but an exceptionally large number of cases of acute poliomyelitis (infantile paralysis) occurred, namely, 1,489 compared with 768 in 1937, and still fewer in the previous three years. There were 65,000 notifications of diphtheria, 4,000 more than in 1937, though the deaths (nearly 3,000) remained practically the same. An efficient method of artificial immunization for the prevention of diphtheria is now available, by means of which this disease has been almost stamped out in certain American and Canadian cities. It is regrettable that immunization is not more widely practised in Great Britain, particularly as welfare authorities have, and local authorities can obtain, powers to adopt it. Eighteen cases of smallpox were notified in 1938, with three deaths, the first deaths from this disease to have occurred since 1934. Here again it is disturbing to find that infantile vaccination has been steadily declining, so that in 1937 only 34 per cent of that year's infants were vaccinated.

Much information is given in the report upon housing and town planning. Slum clearance and rehousing has been proceeding and continues to grow, together with abatement of overcrowding. The total number of houses completed by local authorities during the year was 101,744, the highest number in any year since 1927–28. The Housing (Financial Provisions) Act, 1938, which has come into operation, contains provisions for the encouragement of the building of new houses for the agricultural population, and should improve the conditions of agricultural workers and benefit agriculture, for "the lack of cottages supplied with modern amenities is one of the main factors which accounts for the desertion of the land, especially by the younger generation".

Other developments recorded during the year include the passing of the Food and Drugs Act, which brings together for the first time the statute law relating to the purity and soundness of food and drugs, and the receipt of 652,899 initial applications for admission to the new pensions scheme for 'black-coated' workers.

For the first time, a chapter on civil defence is included. This contains two sections, one on evacuation, providing for the movement of some 3,000,000 people in an emergency, which has been successfully carried out since the report went to press, and another on the Emergency Medical Services for the treatment of air raid casualties, which will provide 290,000 emergency beds in England and Wales.

PROGRESS IN SEISMOLOGY

THAT the study of earthquakes has been actively pursued in Great Britain during the year September 1938–September 1939 is indicated in the report of the Committee for Seismological Investigations to the British Association meeting at Dundee, which for the first time since 1912 is without the name of Sir Frank Dyson. His death has been a severe loss to the committee, as his wise counsel was always greatly appreciated by his colleagues.

This forty-fourth report of the committee has been edited by the chairman, Dr. F. J. W. Whipple, who states that another Milne-Shaw seismograph has recently been made for the British Association and sent, together with a high-precision clock, on loan to the Fiji Government at Suva. The need for this to replace the old Milne instrument was brought to the notice of the British Association by the newly formed Seismological Investigations Committee of the Australian and New Zealand Association for the Advancement of Science; and brings the number of such instruments owned by the British Association up to seven.

The records from the Suva station are particularly important for the study of deep-focus earthquakes, since these are frequent in the region to the south-east of Fiji. In the new Suva instrument and other Milne-Shaw seismographs of recent date, Mr. J. J. Shaw has made an improvement by having the agate cups surrounded by light aluminium bands so that the seismograph is not jerked out of action by severe local shocks.

Dr. A. E. M. Geddes has been making observations with the Milne-Shaw instruments at Aberdeen, using the method developed by Dr. A. W. Lee at Kew, to see whether the free motion of the seismograph was in accordance with the mathematical theory of damped periodic motion, and to find whether or not the period could be determined by removing the damping magnets. He found that the agreement with the theory was very satisfactory, but that an increase of the order of 10^{-1} sec. in the period may have been due to damping. Dr. Geddes suggests that this may have been on account of the boom of the pendulum being somewhat paramagnetic.

The Jagger shock recorder built for the Association at Bristol under the supervision of Dr. C. F. Powell has been installed at Dunira, Comrie, Perthshire, in a croquet house, through the courtesy of Mr. W. G. Macbeth. Its position is lat. 56° 23′ 19″ N., long. 4° 2′ 41″ W., three miles north northwest of the Highland boundary fault. The pendulum oscillates in a vertical plane orientated N. 76° E., is adjusted to a period of nearly a second, and is damped by means of a metal fin dipping into an oil bath. It is intended to record only local shocks; the records are obtained on smoked disks, which are changed every twenty-four hours. An anonymous donor has offered to provide for some years an honorarium to the keeper, and this has been gratefully accepted by the committee. During the year the chief local shocks recorded at Comrie have been October 15, and November 12, 1938, January 23, May 26, 31, and June 11, 1939. None of these was recorded by other seismographs in Great Britain or felt by people. They may be supposed to have been due to movements at the boundary fault. British tremors probably due to subsidences have been reported to Dr. Dollar as having occurred at Brierly, Yorkshire, on November 12, 1938, and at Porth, Glamorganshire, on December 18, 1938. From October 1939 Dr. Dollar will be pleased to receive observations of British earthquakes at the Geology Department, University of Glasgow.

At Oxford the work of the International Seismological Summary has continued, and through the courtesy of the American Museum of Natural History in New York, two Mollweide projection maps centred on 160° longitude have been prepared, one for deep focus epicentres and the other for all epicentres used in the I.S.S. during the years 1913–1933. Copies of these maps were sent to Washington for the meeting of the International Union of Geodesy and Geophysics held last month, and it is noteworthy that at this meeting a seismological committee under the chairmanship of Dr. S. W. Visser was to discuss technical details concerning the I.S.S., including the possible use of geocentric co-ordinates instead of geographic co-ordinates. Dr. H. Jeffreys, who has been appointed a member of this international committee, has been active recently in computation, chiefly from the data of deep-focus earthquakes, of the travel times of various phases of earthquake waves, including those reflected and refracted at the core. For this latter purpose the radius of the outer core had to be evaluated from the available data, and this is now estimated to be 3473 ± 4 km. Dr. R. Stoneley has continued his study of Rayleigh waves and Love waves, and now believes that significant differences in the relative frequency of these in different earthquakes imply differences in the types of initial movement at the foci. One of the pioneers of British seismology was the late Dr. John Milne, who wrote the book "Earthquakes and other Earth Movements". As a result of the progress made, often as the result of work initiated by Milne himself, Dr. A. W. Lee has practically had to rewrite this book though keeping to the form devised by Milne. The revised book has been published during the year under the title "Earthquakes and other Earth Movements" by J. Milne and A. W. Lee (see Nature, **143**, 872; 1939).

THE ETHYL-THIOGLUCOSIDES AND A NEW MONOACETONEGLUCOSE

In attempting to synthesize disaccharides from glucosediethylmercaptal, Brigl, Gronemeier and Schultz (*Ber. deutsch. chem. Gesell.*, May 1939) have obtained an ethyl-thioglucoside with properties very different from those of the α- and β-forms described by Schneider and Sepp (*Ber.*, 1916 and 1918). It is now maintained that the new strongly dextro-rotatory compound and the lævo-rotatory so-called β-form both possess the pyranose ring structure, whilst the dextro-rotatory α-form must be a furanoside. Convincing proof of the structure of this furanoside is obtained from experiments with acetone derivatives in which the 5.6 positions must be occupied by the *iso*-propylidene group. By condensation of glucose diethylmercaptan with acetone in presence of a finely powdered preparation of copper sulphate from which just half the normal water of crystallization had been removed, 5.6-monoisopropylidene mercaptal was prepared, from which, with the aid of mercuric chloride and cadmium carbonate, 5·6-acetonethioglucoside was formed.

Any doubt as to the positions occupied by the isopropylidene group is removed by the elimination in one stage of the two mercaptan groups of the mercaptal with formation of a hitherto unknown 5.6-monoacetoneglucose, which reacts with more acetone to give the well-known 1.2.5.6-diacetone derivative. Thus Schneider and Sepp's α-compound must be a furanoside and the new monoacetoneglucose a glucofuranose, since the possibility of forming a pyranose ring is definitely excluded.

An interesting reaction occurs between this glucofuranose and Schiff's reagent. The colour is restored slowly but clearly within a few minutes and fades again after long standing. This is explained by the tendency of the furanose to revert first to the aldehydic open-chain structure and later, after fission of the acetone group in the presence of acid, to the more stable pyranose ring. The β-pyranose structure of Schneider and Sepp's β-compound is inferred from its synthesis from acetobromglucose by interchange of halogen for the mercaptan group.

No definite proof of the structure of the new ethylthioglucoside is given, but its stability to acid leads the authors to infer that it must be the corresponding α-pyranoside. It was prepared by condensing glucose-diethylmercaptal with glucose in acid solution and was purified by conversion to its tetracetate, which was isolated in a pure state and hydrolysed by baryta to the α-thioglucosepyranoside. A remarkable property is its high specific rotation, +268·8°, which is about 100° higher than the value calculated from Hudson's rule.

ELECTRICAL EQUIPMENT OF BUILDINGS

THE new (eleventh) edition of the regulations of the Institution of Electrical Engineers for the wiring of buildings was published in June (London: Spon. Cloth 1*s*. 6*d*. net; paper cover 1*s*. Also from the Institution of Electrical Engineers).

These regulations enumerate the main requirements and precautions considered necessary for ensuring satisfactory results, including safety from fire and shock, in connexion with the distribution of electrical energy in and about all types of dwelling houses, business premises, public buildings and factories, whether the electric supply is derived from an external source or from private generating plant. With a public supply they are only applicable to the consumer's side of the consumer's terminals. In no circumstances are they applicable to telephone circuits other than radio circuits; and they only apply to radio circuits where such circuits are connected directly or indirectly to a public or private supply system. Primarily the regulations are intended to apply to low-voltage installations, but the cases of electrode water heaters, luminous discharge tubes and electric signs are mentioned. They are not intended to take the place of a detailed specification or to instruct untrained persons. Whenever applicable they are supplementary to statutory regulations, such as those issued by the Electricity Commissioners and by the Home Office, and they include also the requirements for theatres and for safety in mines.

Various methods of carrying out the electrical equipment of buildings are considered and in order to guard against the risk of fire and shock the method selected must be suitable for the voltage, the atmospheric conditions, the size of the installation and the type of building. There is no intention of discouraging invention or of excluding other materials and methods which may be approved in the future.

The Committee of the Wiring Rules is fully representative of all those connected with the industry. It has representatives from the Association of Consulting Engineers, the B.E.A.M.A., the Cable Makers Association, the Fire Offices Committee, the Home Office, the Electrical Contractors Association and others. The Committee holds meetings periodically and all difficulties are fully discussed and reported on. The revision has been carried out very thoroughly, but contractors whose work has hitherto been of the highest quality will not be affected.

REINFORCED CONCRETE COLUMNS

UNDER the usual applications of column theory the theoretical values for loads at failure are dependent on the elasticity of the material of which the column is made, and it is assumed in this theory that the material is both homogeneous and isotropic. In the case of reinforced concrete this assumption cannot be made, so that the applicability of the usual theories is not justifiable without experimental evidence of the actual failing loads. In particular, the effect of inelastic deformations of the concrete requires to be investigated.

An investigation, undertaken to determine the strength of long columns in short-period loading tests to destruction for cases where the initial eccentricity of loading is so small as to be capable of being regarded as 'accidental' in practice, has been carried out at the Building Research Station, Garston, in co-operation with the Reinforced Concrete Association and under the supervision of Dr. W. H. Glanville. A report has been published by the Department of Scientific Research by the issue of a Building Research Technical Paper (No. 24. H.M. Stationery Office. 9*d*. net), which is the seventh in a series of Studies in Reinforced Concrete.

Even for well-defined initial conditions of loading, it is impossible to carry out a rigorous mathematical analysis of the stress distribution which, by reason of the effects of creep, must be in some way a function of the time the material is under load. The experiments have shown, however, that a simple approximate analysis can be used to estimate the strength of long columns under the conditions specified. The paper opens by showing how an expression may be derived for the value of the ratio of the applied load to the short column load in terms of the Euler load, the short column load and a coefficient proportional to the slenderness ratio. The short-period tests to destruction are analysed and cited to show this formula to be satisfactory for particular values of this coefficient.

The tests were made on columns 6 in. square in section, but in some cases, where high values of the slenderness ratio were required, a 3-in. square section was used. The columns and the arrangements for testing are illustrated by photographs and the test results are set out in tables and diagrams in which are shown also comparisons between the theoretical and the practical figures.

SCIENCE NEWS A CENTURY AGO

Sir William Jardine's "British Salmonidæ"

"A work of considerable, and in some respects of national importance," said the *Athenæum* of October 19, 1839, "has long been in preparation, and one number published by Sir William Jardine on the 'Scottish Salmonidæ'. The announced intention was a series of plates, illustrating the different species, accompanied by an octavo volume of descriptive letter-press. . . . Though the work was nominally restricted to Scotland, because the numerous lochs, rivers and mountain streams in that country offered the greatest facility for extended observation, it would of necessity have included almost all the British species. . . . Now our readers will hear, as we did, with surprise, that notwithstanding the scientific interest which must attach to such a work—notwithstanding the direct pecuniary interest, which many persons must have in the subject, and even its legislative importance, for we have had at least half a dozen different committees of inquiry appointed by Parliament or the Government—the work is likely to be abandoned for want of patronage—even though Sir William Jardine has consented to proceed with it if but sixty subscribers could be obtained, sufficient only to secure him against direct pecuniary loss. Surely with so many noblemen and gentlemen interested in the questions to be resolved by such a work—so many Scientific Institutions, so many Societies professedly devoted to inquiries in Natural History, scattered over the three kingdoms, this announcement will be sufficient to ensure its completion."

The author of this work, which ultimately appeared under the title "History of British Salmonidæ", was the distinguished naturalist Sir William Jardine, Bart., who was born in Edinburgh on February 22, 1800, and died on November 21, 1874, in the Isle of Wight. Entering the University of Edinburgh at the age of seventeen, he attended the lectures of Prof. Jameson and devoted himself to natural history and anatomy. At the age of twenty-one he succeeded to the title and estates in Dumfriesshire. With Prideaux Selby (1788–1867) Sir Stamford Raffles (1781–1826) and others he published "Illustrations of Ornithology" and at his home, Jardine's Hall, Dumfriesshire, formed one of the largest collection of birds in the country. His other writings included the "Memoirs of Hugh Strickland" and an edition of White's "Natural History of Selborne", and for seven years he was joint-editor of the *Edinburgh Philosophical Journal*. In 1860 he was appointed commissioner on salmon fisheries.

The Royal Navy and Screw Propulsion

On October 16, 1839, an experimental trip was made in the Thames with the S.S. *Archimedes* fitted with the screw propeller of Francis Pettit Smith, the trial being attended by Captain Sir William Symonds, the Surveyor of the Navy, Captain Sir William Edward Parry, the head of the Steam Department at the Admiralty, Captains Basil Hall, Austin and Smith, R.N., Peter Ewart the chief engineer of Woolwich Dockyard, Joseph Miller, Charles Manby and others. In the following spring the *Archimedes* was tried against H.M.S.V. *Widgeon*, a paddle-wheel vessel employed on cross-channel mail service, and it was the success of the *Archimedes* which led to the introduction of the screw propeller into the Navy.

APPOINTMENTS VACANT

Applications are invited for the following appointments, on or before the dates mentioned:

Secretary (woman) for the Macaulay Institute of Soil Research—The Director, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (October 21).

Headmastership of Epsom College—The Secretary, Epsom College, Epsom, Surrey (October 25).

Temporary Lecturer in Gardening—The Principal, Cheshire County Training College, Crewe.

PLANNED INTERNATIONAL ECONOMICS

THE high position of the annual reports of the Director of the International Labour Office among current reviews of the industrial and economic condition of the world has been earned only in part by the large resources of knowledge upon which they can draw. It is equally due to their wide outlook, measured but unequivocal judgment and their lucid estimate of tendencies and conditions, free from excessive detail of the work of the organization. These are largely due to personal qualities, and it is indeed a high tribute to Mr. J. E. Winant that his first annual report so admirably maintains the high standard set by his predecessors*. The fact that this report was published before the outbreak of war in no way lessens its present value.

Under the title "The World of Industry and Labour 1939", Mr. Winant reviews in succession the economic setting, the conditions of work and the standards of life. He emphasizes the way in which research and discussions on business cycle policy have led to general agreement that, whatever the initial cause of a business decline, active steps can be taken to prevent the secondary effects which used inevitably to follow it, and that this can be achieved by maintaining consumers' demand and by well-prepared public investment to replace rapidly any decline in private investment. This new attitude is conspicuous in the United States, and economic policy in Great Britain has shown similar features. While, however, the recession of 1937–38 presented mainly a problem of getting unemployed people back to work, the general concentration on problems of national defence has given a new turn to the economic situation. In this situation the urgency of meeting essential needs of national defence tends to cut into the standards of living, which it is the work of the International Labour Organisation to endeavour to raise.

To minimize such an effect it is first desirable to increase armament production so far as possible by utilizing unemployed resources, so as not to disturb ordinary peace-time activities more than necessary. Secondly, when it is necessary to restrict other types of activity or production, care should be taken to confine such restriction to the minimum and to those fields which least jeopardize present and future standards of living. While both public spending designed as a recovery measure and expenditure on armaments cause an initial increase in activity, the latter must be accompanied by measures to prevent expansion of consumption and a rise in standards of living.

These threats to established standards and the growing pressure on resources accentuate the importance of international economic co-operation. The rising standard of living in modern times has been made possible by the expansion of markets and the world-wide exchange of raw materials, finished products and capital investment. The hope of further progress rests on the continuance of this process.

The main problem is always to organize world economy in a way that will utilize fully the capacities of mankind in the production of the goods and services needed to raise the standard of life. Mr. Winant's survey of conditions of work indicates how true this is of internal economy also. Political conditions have been the main factor determining the check on the movement for shorter hours and the hesitation in giving effect to the application of the principle of the forty-hour week adopted by the Conference in 1935. This remains, however, a permanent problem of social and economic policy, and the realization of shorter working hours is one of the great additional benefits that will be assured when nations will agree to a just and lasting peace.

---

*The World of Industry and Labour, 1939. International Labour Office. Report of the Director. (Geneva: International Labour Office. 2s.).

There are, however, directions in which progress has been made. The development and extension of social insurance and the widespread attention being given to problems of nutrition, whether from the scientific side or in Government efforts to raise the level of nutrition by means of education and publicity, are noteworthy examples. Housing also is a matter in which the State is taking a more active part.

What is of special interest in Mr. Winant's survey is the way in which he indicates the extent to which solutions of these problems were being attempted in many countries, and frequently by very similar methods, however different the objectives or main character of policy. This is scarcely less striking than the equally emphatic conclusion that success in this matter of improving standards of health and labour and living conditions can only be imperfectly achieved except through co-operation between the nations.

This report is, however, of further interest for the admirable review of the twenty years' work which has now been completed by the International Labour Office. This record of development as well as of achievement is a welcome reminder of the value of international co-operation. The continuous constructive effort by which the International Labour Conference has developed its technique is at least as impressive as the record of its achievement in establishing an international labour code and in assisting the organization and co-ordination of social policy on which the improvement in living and working conditions depends. The work of the Conference on Migration for Settlement and of the International Public Works Committee are striking illustrations of the latter tendency in the last two years.

Besides this, the International Labour Office has functioned as an international clearing-house of information on labour and social questions. All these activities are based on its research work, and this possesses two special advantages. In its research work the International Labour Office must of necessity use the method of international comparison. The comparative method is to the student of social science what the laboratory is to the physicist. The Office cannot make experiments, but it is able to study the same phenomena in many different countries and thus eliminate what is accidental in the experience of any particular country and emphasize those things which are fundamental to all. Further, the International Labour Office is well placed for bridging the gulf between theory and action by bringing the conclusions reached directly before those capable of acting upon them.

Such research work, coupled with the broad view and tripartite character of the International Labour Office which naturally follow from its constitution, have already assisted it, in such fields as economic depression and unemployment, or in that of industrial diseases, like silicosis, or the standardization of labour statistics and improvement of their comparability, to guide world opinion towards more effective methods.

The extent to which the International Labour Office has succeeded in the last twenty years in furthering steady social progress is at least reason for not losing confidence or hope. The full contribution of the Office to effective international collaboration is not to be measured only by such activities. In approaching labour and social problems, we are forced to face the economic consequence of war and peace, whether in relation to trade conflict or war economy. When the present war comes to an end, the countries of the world will have to face the tremendous problems of readjustment to a peace-time economy. Economic re-employment problems will demand urgent solution. Some means of absorbing workers thrown out of employment by the slowing down of armament production will have to be devised.

In facing such difficulties the International Labour Office already possesses resources of immense value, but if it is to render the greatest possible service its energies must be directed now to the problems that lie ahead. The research work required must be commenced in this period of tension and uncertainties if we are to ensure that the mistakes of the past are not to be repeated. It is on this fact as well as on the proved value of the Organisation that Mr. Winant bases his appeal for financial support and for the resources which will enable it to function effectively. The extent to which the services of scientific workers are being enlisted at the present time should not lead them to overlook their responsibilities for participation in the constructive work of thinking out and planning the implications of a real peace.

THE SCIENTIFIC STUDY OF SOCIETY

The Study of Society
Methods and Problems. Edited by F. C. Bartlett, M. Ginsberg, E. J. Lindgren and R. H. Thouless. Pp. xii+498. (London: Kegan Paul and Co., Ltd., 1939.) 10*s*. 6*d*. net.

SINCE the autumn of 1935, a competent group of British psychologists, anthropologists and sociologists, ultimately twenty-three in number, has been meeting twice yearly in discussion. This unique, invaluable book, comprising nineteen chapters written by seventeen members of the group, is the outcome of their deliberations. Each chapter, we are told in the preface, "was first written by the group member whose name appears at its head. It was then duplicated and sent to all the other group members, so that it could be criticized and discussed at the next meeting of the group. . . . The criticism has been free and often drastic, but mainly constructive. Every member of the group has played a part in this discussion, and the volume is thus, in a literal sense, a co-operative product."

The purpose of the book, the preface explains, is to offer guidance to would-be investigators of social problems who "ask 'What shall we do?' and 'How shall we do it?' . . ." The preface further states that "the idea which inspired the preparation of the present book" was to issue for the benefit of prospective workers in the field of complex societies a companion volume to the well-known "Notes and Queries on Anthropology", first published in 1874, the aim of which was "to promote accurate anthropological observation on the part of travellers and to enable those who are not anthropologists themselves to supply the information which is wanted for the scientific study of anthropology at home".

Prof. F. C. Bartlett, in his important, but admittedly difficult, chapter on "Suggestions for Research in Social Psychology", addressed mainly to the laboratory psychologist, has no doubt as to the value of the contributions which the untrained worker can make to the subject (p. 25); and this view is supported, although with less enthusiasm, by Dr. R. H. Thouless (pp. 126, 127) in his carefully written contribution, "Scientific Method and the Use of Statistics". Prof. Bartlett lightens the last three pages of his article by devoting them to the amateur investigator, giving him eight useful hints and cautions, and eight promising themes of research. But in the rest of the book, save in Dr. Nadel's contribution, "The Interview Technique in Social Anthropology", which makes several references to "Notes and Queries in Anthropology", the practical interests and limitations of the untrained worker are largely ignored.

The nineteen chapters of this book are written with a quite unusual degree and uniformity of ability. They vary widely in length from the seven pages of Mr. E. Farmer's too meagre article on "The Study of Social Groups in Industry" to the fifty-two pages of Dr. E. J. Lindgren's article on "The Collection and Analysis of Folk-lore", which, like Prof. M. Ginsberg's deeply philosophical and learned chapter on "The Problems and Methods of Sociology", would rank as a 'classic' had it appeared in an encyclopædia, but is only to be grasped thoroughly by an advanced student of the subject. Less excusable is the surprising latitude which has been allowed to each member of the group in the mode of treatment of his subject. Stricter and single leadership of the group would have resulted in greater formal homogeneity and in a closer adherence to the three cardinal objects of the book: description of methods, summary of results already achieved, and mention of the outstanding problems at present most deserving of attack.

The failure of certain contributors to fulfil these objects is due to different, and sometimes excusable, causes. For example, Prof. T. H. Pear's chapter on "Some Problems and Topics of Contemporary Social Psychology" covers far too many topics: it is necessarily diffuse and superficial and appears at first sight popular and at times even trivial, but a second reading reveals considerable thoughtfulness in its preparation. On the other hand, the very subject of Dr. J. T. MacCurdy's interesting, though provocative, chapter on "The Relation of Psychopathology to Social Psychology" precludes much reference to past results and future problems. Again, Dr. Audrey Richards's contribution, "The Development of Field Work Methods in Social Anthropology", which is a veritable mine of information, thoughtfully and practically presented, and containing more than a hundred and twenty references, deals, as perhaps its title justifies, only with methods, not with results; and in her chapter on "Modern Trends in Child Psychology", Dr. Mary Collins makes virtually no attempt to indicate to the future investigator what are the most pressing problems that demand study. Indeed, this is scarcely to be expected after the impression, produced on her by her survey, "of a somewhat disordered array of experimental and test results, statistics and minute observations. It is often difficult to understand with what aim a particular investigation has been undertaken, or what importance should be assigned to the conclusions which are claimed to be established" (p. 85). Perhaps the most stimulating chapter for the quite untrained worker is that contributed by Miss Clement Brown on "The Methods of Social Case Workers", obviously the product of mature and wide experience and of unusual wisdom; while for the general reader Mr. A. Rodger's succinct but excellent chapter on "The Work of the Vocational Adviser" could not be bettered.

So many excellent articles—some of them (especially those by Prof. Bartlett, Prof. Ginsberg, Dr. Lindgren and Dr. Richards) brilliant—deserve to have been presented in a more attractive *format*, on pages with ampler margins and less crowded with type. This might, in the reviewer's opinion, have been achieved by the omission of the subjects of certain chapters, for example, those on intelligence tests, attitude tests, rating scales and the use of statistics, which are scarcely suitable for such a volume as this or have already been at least as adequately treated elsewhere. Dr. C. J. C. Earl's contribution, "Some Methods of Assessing Temperament and Personality", written from the clinical point of view, a last-moment substitute for an article by Dr. R. B. Cattell who, owing to his departure for the United States, was unable to preserve his membership of the group, seems also scarcely suitable; and Dr. O. A. Oeser's contribution, disappointing in the scanty information it provides of the Dundee Survey of which he was in charge, might have been more briefly included in Mr. A. F. Wells's chapter on "Social Surveys".

"The first aim," claims the preface, "which the group has set itself is achieved." This is undeniably true. Nowhere will the reader find so complete, so reliable, so illuminating and so critical an account of the methods of psychology, anthropology and sociology applied to the study of the problems of complex—and primitive—societies. Only by the wise use of such methods can man come to a final understanding of the social factors that determine harmony and conflict between groups and nations.

COMMERCIAL DEVELOPMENT OF AFRICA

Capital Investment in Africa
Its Course and Effects. By Prof. S. Herbert Frankel. (Issued by the Committee of the African Research Survey under the auspices of the Royal Institute of International Affairs.) Pp. xvi + 487. (London, New York and Toronto: Oxford University Press, 1938.) 10*s*. 6*d*. net.

When Lord Hailey was formulating the plans for the African Research Survey, Prof. S. H. Frankel was asked to prepare a memorandum on the course of capital investment in Africa. At the time, he doubted whether it would be possible to gather sufficient information in the time available, but eventually he undertook the task. Soon the study outgrew its modest origin and has consequently been published as a separate volume. The work is very fully documented and has more than a hundred detailed tables as well as a number of graphs, but the innumerable footnotes make the book a difficult one to read, more especially as many of the footnotes form really an essential part of the text.

For centuries Africa south of the Sahara played but little part in world economy. Africans had little to offer and as little to demand from traders, and hence came the slave trade—a trade which automatically destroys all others. Even the temperate lands of South Africa were regarded only as important in guarding the routes to India. The change came with the discovery of minerals in South Africa, and in a single generation European powers established sovereignty over most of Africa (that is, Africa south of the Sahara, to which the whole work refers). So late as 1878 only a quarter of the continent was occupied by Europeans; now it is the whole, with the exception of Liberia. Prof. Frankel dismisses in a page and a half the natural factors which retarded the 'opening up' of Africa, so that the scientific worker must regard his study as complementary to the main work, Lord Hailey's "An African Survey", and not as complete in itself. Yet such an economic study confirms conclusions based on other grounds.

The task of developing tropical Africa proved beyond the resources of the chartered companies—even though patriotic investors continued to find money without any return for half a generation—with the result that half of the £1,222,000,000 invested in Africa has been invested by Governments or public authorities. Even in the temperate south, the story is one of constant struggle in a land of outposts—until diamonds and then gold brought the economic revolution to South Africa. The value of diamonds produced in the Union has exceeded £320,000,000; £80,000,000 has been paid in dividends and from 1911 until 1937 alone the Union Government received nearly £33,000,000 in taxation from the industry. That the Government revenue fluctuated from more than £4¼ millions in 1929 to less than £150,000 in 1916 or £350,000 in 1934 presents another side of the picture. Despite the very successful development of the world's greatest gold field, it is estimated that the net returns on capital in Rand investments is only 4·1 per cent.

In recent years, as British investments in foreign countries have decreased, the proportion devoted to African issues has increased to about a quarter of the total foreign issues made in London. In this connexion Tables 46–48 are particularly interesting. No less than 77 per cent of the total capital invested in Africa is in British territories (with 85 per cent of the total trade). The Union of South Africa has received 43 per cent of the total capital and has 55 per cent of the total trade (1935). In the general position, there has been extraordinarily little change in the last thirty years so far as the relative position of British and French territories are concerned, but from 1907 until 1935 the share in the trade of the Union decreased from 61 to 55 per cent, whilst East Africa increased from 6·3 to 9·7 per cent. Those countries which show the smallest return, as expressed by value of foreign trade, in proportion to the capital which has been invested, include Tanganyika, South-West Africa, Angola, Mozambique, the Congo and the Cameroons. The best figures are shown by West Africa (Gambia, Sierra Leone, Gold Coast, and the French Territories). These facts give much food for thought, and indeed the whole work is a remarkable commentary on what is known of natural conditions and resources. L. D. S.

PATHOLOGICAL PROBLEMS OF FRUIT AND HOPS

Diseases of Fruit and Hops
By Dr. H. Wormald. (Agricultural and Horticultural Handbooks). Pp. 290+40 plates. (London: Crosby Lockwood and Son, Ltd., 1939). 17*s*. 6*d*. net.

Any advance in the most important science of plant pathology is soon common knowledge to scientific workers through the medium of scientific papers, but there still remains the necessity of passing on such knowledge to the grower. Authentic and reliable information of this kind must always be of interest and value, but good books appear all too seldom, and in the volume here reviewed it is stated that none has been printed on this particular subject since 1920.

It is therefore pleasant to welcome this account of the "Diseases of Fruit and Hops", written by Dr. Wormald, who has been plant pathologist at the East Malling Fruit Research Station for many years. It is a companion volume to one written some two years ago on insect pests of the same crops by Dr. Massee of the same research station.

There are fifteen chapters, the first three being devoted to approaching the subject in a general way before dealing with the specific diseases. Chapter i opens by discussing the factors which influence the growth of plants for good or ill and so determine whether they will be healthy or otherwise, quite apart from the question of attack by disease organisms. Then follows a description of the types of disease that may occur, bacterial, fungal, or virus, and particular stress is laid on that class of disorder resulting from unfavourable environmental conditions, the so-called 'functional' diseases which hitherto have been somewhat neglected by investigators. General principles for avoiding such troubles are given in some detail. Chapter ii deals with the making and the application of fungicidal sprays, with advice on suitable machines for this work. Chapter iii is taken up with descriptions of about a dozen outstanding diseases, each affecting many kinds of fruit trees, although each is again mentioned under its various hosts.

In the next eleven chapters we find a score of fruit plants and the hop plant dealt with either singly or in groups of similar types of fruits. The arrangement is to group the diseases at the beginning of the chapter, and then for each host in turn to describe the symptoms of the various diseases which may appear on its organs, taken in the order root, stem, leaf and fruit. The intention is to help growers to recognize the symptoms easily and thus identify the cause of the trouble. After each symptomatic description, suitable remedial measures are briefly discussed and in each case a limited number of references to further literature is supplied.

The last Chapter (xv) contains descriptions of several important fruit diseases which have not yet been recorded in Great Britain, some of which are so destructive that it is unnecessary to emphasize the value of such information to growers. The end of the book contains three indexes, one of popular names, one of scientific names, and one of authors.

The book is up to date and the author has discussed control measures in a practical and simple manner that will be appreciated by growers. The descriptions of symptoms are good on the whole, though the grower may not find these so readable. The author in his preface expresses the hope that the book will be of some interest to students, but in our view these should be catered for in a separate book. It is unlikely that the average grower will appreciate descriptions of microscopic spores or their measurements in microns. We feel that much space occupied by technical detail could have been used to better purpose. In any event, the drawings of microscopic objects on pp. 57, 58, 188, 245 and 266, give no indication of the magnification and might be most misleading. An excellent feature is the provision of forty plates containing no fewer than 130 photographs, but in the case of several diseases the text contains no reference to the appropriate plates.

There are some outstanding omissions. For example, silver leaf disease is fully dealt with but there is no mention of the very common and externally similar appearance known as 'false' silver leaf which may call for very different treatment. Again, when discussing the serious virus disease known as 'yellow edge' of strawberries, little mention is made of those so-called 'carrier' varieties, which, though infected, show no obvious symptoms for a considerable time; yet it must be important for growers to be made aware of the danger of trusting such plants near stocks which may be rapidly destroyed by the virus. In dealing with glasshouse fruit plants there is much more that could have been included, but perhaps this is not of very great importance in a book principally concerned with hardy fruits.

Despite these criticisms, the book should be a very valuable asset to fruit-growers. The diseases have been dealt with in a clear and able fashion by one of the foremost authorities on pathological problems connected with hardy fruit production.

D. E. Green.

ANTHOLOGIA ANTHROPOLOGICA

(1) The Native Races of Australasia

Including Australia, New Zealand, Oceania, New Guinea and Indonesia. A Copious Selection of Passages for the Study of Social Anthropology from the Manuscript Notebooks of Sir James George Frazer. Arranged and edited from the MSS. by Robert Angus Downie. (Anthologia Anthropologica.) Pp. vii + 390. (London: Percy Lund, Humphries and Co., Ltd., 1939.) 35s. net.

(2) The Native Races of Asia and Europe

A Copious Selection of Passages for the Study of Social Anthropology from the Manuscript Notebooks of Sir James George Frazer. Arranged and edited from the MSS. by Robert Angus Downie. (Anthologia Anthropologica.) Pp. vii + 400. (London: Percy Lund, Humphries and Co., Ltd., 1939.) 35s. net.

(1) IN the second volume of extracts from Sir James Frazer's notebooks, the principle of selection remains unchanged. In the main, material which has been used as evidence in his works has been omitted; and preference has been given to early or obscure sources, which would be outside any but an almost exhaustive knowledge of the literature. Hence it has been possible to give due recognition to the careful observation which has been made by Dutch travellers and officials of the natives of Holland's possessions in Indonesia. In these extracts from early travels, or from records appearing in periodicals and publications difficult of access to English readers, much material will be found of the greatest value to the student for the less familiar peoples of Sumatra, Java, Celebes and others of the more remote islands of Indonesia.

Although the records of the natives of the geographical regions covered by this volume—for example, Australia, New Zealand, Melanesia and in a lesser degree Polynesia—are among those most familiar in ethnographical literature, it will nevertheless be found that Mr. Downie's editing has made a most successful gleaning from the less well-known fields; but most welcome among his citations are the extracts from manuscript sources communicated direct to Sir James by their authors. Among these, two in particular require mention—one a note on the existence of totemism in Fiji by the late W. H. R. Rivers, which is an instructive example of his care in inquiry and his cogent method in ethnographical argument; and the second some observations by the late A. W. Howitt on the natives of south-east Australia, which are drawn from an unpublished work by that distinguished Australian anthropologist, and of which Sir James promises early publication.

(2) In this volume of extracts, it will be found that though "The Golden Bough", the "Folklore of the Old Testament", and other of Sir James's works have drawn liberally on the sources, the store is

still far from depleted, and much has remained for inclusion here of interest and of value for the student of magic, ritual and belief. Especially interesting are the extracts from the records of early Catholic missionaries, whether they deal with Tibet, Indo-China, or the Chinese Empire. Among the Tibetan, Chinese and Japanese extracts, especially valuable are those which include some of W. W. Rockhill's less accessible notes; while the records of the Korean and Siberian peoples might well serve as a starting point for a study of 'possession' and shamanism. The extracts from John Richardson's travels in Persia, which deal with a little-known side of Persian traditional belief, the angelic associations of the months, are of noteworthy interest for the study of the developments of magical thought in the East.

It was, perhaps, inevitable that the European material should scarcely lend itself to the treatment, which has proved so favourable in dealing with the records of more primitive peoples. The literature is both too familiar and too extensive. Hence these extracts, by contrast, must seem scrappy. Nevertheless, there is much of interest and value, among the more notable being early accounts of the northern form of witchcraft in Lapland and Scandinavia, with the southern European vampires and witches in contrast, and of the survivals in Central Europe of the worship of pagan deities.

The work of editing these extracts has been carried out by Mr. Downie once more with meticulous care, and he has enhanced their utility by a series of illustrative maps and a comprehensive index.

ARTIFICIAL RADIOACTIVITY

(1) Atomes, radioactivité, transmutations

Par Maurice de Broglie. (Bibliothèque de Philosophie scientifique.) Pp. 270. (Paris: Ernest Flammarion, 1939.) 22 francs.

(2) Künstliche Radioaktivität und ihre kernphysikalischen Grundlagen

Von Prof. Dr. W. Hanle. Pp. viii+114+7 plates. (Jena: Gustav Fischer, 1939.) 12 gold marks.

(3) Künstliche Radioaktivität: Experimentelle Ergebnisse

Von Dr. Kurt Diebner und Dr. Eberhard Grassmann. Pp. xi+87. (Leipzig: S. Hirzel, 1939.) 12 gold marks.

(1) THE first of these books represents one of the most pleasing accounts of the present position of nuclear physics that the reviewer has read. It gives a most up-to-date description of the neutron and its properties, of natural and artificial radioactivity and of the new chemistry of the nucleus, couched in very clear language and eminently suitable for the general reader. At the same time, all important features of modern work in these branches of physics are covered in an extraordinarily complete manner. The work can confidently be recommended to all students, particularly those who wish to improve their knowledge of French.

(2) The second book is also meant for the general reader, but it is rather more restricted in its range of subject-matter. It gives a brief introduction to the fundamental conceptions of the structure of the atom, a description of the elementary particles of modern physics and their role in nuclear structure, and a short but very beautifully illustrated account of the experimental methods used in experiments on nuclear transformations. It is a sad reflection that in recent years Germany has taken so little part in the development of these methods. The book also describes in some detail the various types of nuclear changes and the methods of producing artificial radioactivity, a special section being devoted to γ-radiation. It concludes with a few remarks on possible applications of the results of nuclear physics experiments to chemistry, biology, medicine and technology, and contains a striking series of coloured graphs illustrative of the transformations of natural and artificial radioactive elements.

(3) The third book is really a very valuable set of physical tables. In it are set forth the data on artificial radioactivity published up to September 1938. There is no attempt at describing the methods of experiment or of analysing the results in a critical manner. The work is intended as a reference book for the research worker and the teacher who wishes to know whether a particular nuclear reaction has been studied, and so on. A list of nearly 350 references is given, and in addition to a full analysis of the separate nuclear reactions for each element under such headings as artificial radioactivity produced by α-rays, artificial radioactivity produced by protons, etc., the data is also set forth in tabular form. A very large coloured diagram or graph of the stable and radioactive isotopes is included.

L. F. Bates.

ENGINEERING BIOGRAPHY

Great Engineers
By Prof. C. Matschoss. Translated by Dr. H. Stafford Hatfield. Pp. xi+381. (London: G. Bell and Sons, Ltd., 1939.) 12*s.* 6*d.* net.

IN this entertaining volume of biographical studies of some forty mechanical engineers, mainly German and British, the last notice is of Oskar von Miller (1855–1934) who on his seventieth birthday, May 7, 1925, had the satisfaction of witnessing the opening of the "German Museum of Masterpieces of Science and Technology", otherwise known as the Deutsches Museum or the Munich Science Museum. As a young man Miller had visited Woodcroft's Patent Office Museum at South Kensington, and the Conservatoire des Arts et Metiérs in Paris, and had been impressed with the thought that no such museum existed in Germany. After a successful career as an engineer his thoughts again turned to the question of a technical museum for his native land, and in 1903 he was able to found a society for the promotion of such an institution. To this object he devoted his time and energy unstintingly and with great success. Germany now has a museum worthy of her own great contributions to industrial enterprise, and representive of mechanical progress throughout the world.

In the task of familiarizing German students with the work of the great pioneers Dr. Matschoss, the author of this volume of biographies, has played a part second only to that of von Miller, whose efforts he furthered in every possible way. As editor of the publications of the Verein deutscher Ingenieure, then as director of the society, as the author of historical works and as a lecturer he has become known in both hemispheres as an authority on engineering history. This latest work from his pen, therefore, is no ordinary compilation, but a series of studies by one familiar with every aspect of the subject. It is a volume which should be read by every engineering student. The men recalled came from all sorts of homes, began life under various conditions, but they one and all by the exercise of their talents made notable contributions to knowledge. But, says Dr. Matschoss, "the great deeds of great men are not bound up with their lifetime. They take ever-growing effect in course of time, far beyond the earthly existence of the individual". It is, however, only history which can give us a measure by which a just estimate of great achievements can be made.

The book is arranged in three sections. First there is a brief review of the great engineers of antiquity. This is too short to be of much value and the subject probably did not appeal much to the author.

In the second part is a most admirable chapter on the German gunsmiths and others on Gutenberg, Leonardo de Vinci, Agricola and Otto von Guericke. It is probable no British writer would have included Gutenberg or Otto von Guericke in a volume on "great engineers". The choice, however, can be justified, for as Dr. Matschoss says, "perhaps no technical advance in any field has had so great an effect in promoting development in all other fields of human labour as the invention of printing". Looked at in this light, printing falls within Tredgold's famous definition. Otto von Guericke, it is true, was more of an experimentalist than an engineer, but he carried out his experiments in the manner of an engineer and paved the way for engineering developments. Historians of physical science may be interested to learn that Guericke's experiments with the hemispheres were not made before the Reichstag in Regensburg, in front of the Emperor and the German princes, but at Magdeburg and at a later date than that usually given.

The third and longest section of the book begins with Watt and the pioneers of the steam engine, and the last five studies are of Parsons, Edison, Westinghouse, Carl von Linde and Oskar von Miller. Among the other British engineers dealt with are Trevithick, the Stephensons, Maudslay, Nasmyth, Bessemer, and Sydney Gilchrist Thomas. America is represented by Fulton and by Ericsson, who though born in Sweden passed the greater part of his life in the United States. As might be expected, the studies of German pioneers are particularly good, and those on Holtzhausen, Dinnendahl and Reichenbach contain much information not known generally. But the careers of Alfred Krupp, Werner von Siemens, Otto, Langen, Daimler, Maybach and Diesel, and of Carl von Linde are all equally interesting. One could have wished that Dr. Matschoss had spread his net a little wider and had included one or two sketches of the engineers and inventors of a country which can boast of Seguin, Montgolfier, Fourneyron, Bourdon, Schneider, Giffard, Hirn, Clapeyron, Rateau and many others. We are altogether too unfamiliar with the history of engineering in France.

The book is well printed, the portraits are excellent and there is a good bibliography. There are one or two slips in the text. George Stephenson is stated to be buried near Chester, instead of

Chesterfield, and Robert Stephenson is said to be buried next to Watt in Westminster Abbey. Watt is buried at Handsworth, and Robert Stephenson was laid next to Telford, in the Abbey, at his own request. The statement about Ericsson's *Robert F. Stockton* should be altered to show that she did not cross the Atlantic by steam.

On the whole, many engineers will think that Dr. Matschoss has given us the best volume of engineering biographies so far published. He is naturally proud of the pioneering work of his countrymen, but he says "we are indebted to other nations as much as they are indebted to us".

BIRDS OF BRITAIN

The Handbook of British Birds
Vol. 3. (Hawks to Ducks.) By H. F. Witherby (Editor), Rev. F. C. R. Jourdain, Norman F. Ticehurst and Bernard W. Tucker. Pp. x + 388 + plates 61–92. (London: H. F. and G. Witherby, Ltd., 1939.) 25*s*. net.

THE third volume of this exhaustive work has just made its appearance, and is not inferior to its two successors in its high standard. The value of this volume is heightened by a number of admirable coloured sketches of geese by Peter Scott, his pictures of grey lags and of barnacle geese being particularly fine. Credit is also due to the producers of the book for having brought out so well the fine points of these sketches, always liable to be lost in reproduction. Mr. J. C. Harrison's delicate and masterly delineation of birds also finds a place in this volume. His plates (81 and 82) showing the adult males and females of British ducks in flight are delightful. No bird artist can excel Mr. Harrison in bringing to the mind the sense of movement in birds. His pintail and long-tailed ducks in flight are particularly attractive and he has caught the wise expression in the eye of the tufted duck—an expression which I often noticed in the tufted duck of Fallodon-full-winged birds which had been tamed so completely by Lord Grey that they were entirely without fear.

The birds which are written of in this volume are, among raptores, the falcons, golden eagle and sea eagle, buzzards, harriers, osprey and kite. It is gratifying to know that the kite, which is still confined to strictly protected areas in Wales, has increased from five birds in 1905 to fifteen birds in 1938. Of these fifteen kites, twelve were paired and three young were reared. Of the osprey we have no such cheering news. The two ancestral nesting haunts of this fine bird were on Loch an Eilein on Strathspey, where the last eggs were laid in 1899, and Loch Arkaig in Lochaber, where the eyrie, on the oak tree on the island was last occupied in the year 1902. But there is some evidence that two eggs were laid and one young bird reared in a nest in the same district at a considerably later date than 1902, and even during the present year (1939) there are reports of ospreys being seen in the Highlands.

Geese and swans, herons and bitterns, find a place in this volume, and no fewer than 160 pages are devoted to the British ducks. Here is to be found an interesting map showing the nesting haunts of the eider around the British coasts. It is curious that this fine duck should be numerous at the southern fringe of its range; that it should nest plentifully on the Farne Islands—where it is known as St. Cuthbert's Duck and, it is said, owes its remarkable tameness to the work of St. Cuthbert—and on Coquet Island, and yet should be unknown as a nesting species south of that isle off the Northumbrian coast.

In the notes on the golden eagle—pp. 39 and 40—there are one or two mis-statements which may perhaps be corrected in a later edition. It is said that the golden eagle "formerly bred on sea-cliffs, but is now confined to moorland". This statement should be amended, for there are at the present day several golden eagles' eyries on sea-cliffs in Scotland. Then, again, we are told that the eyrie "in a few cases" is in trees, but in the Central Highlands a tree is a more usual nesting place than a cliff. The eyrie is a bulky structure, and during the summer of 1939 I saw an eyrie in an old pine, and estimated the depth of this eyrie as no less than fifteen feet: the nest must have been of very great age. To the statement that "in the west bracken is a much-favoured nesting material" I would say that in the many eagles' eyries I have examined I have never once found any trace of bracken. It is stated in the notes that fresh eggs are found usually about April 1–10, but in my experience the eggs are found during March 20–31, and any date later than this is unusual.

To the statement that both golden eagles provide food for the eaglets I would say that my wife and I have watched at hides at a number of eyries, and although our watching hours must have numbered many hundred, we *never* saw the female eagle bring in food. The hunting was done entirely by the male, but the female fed the young, and cleaned up the eyrie by carrying away any old carcasses of prey.

It is stated that the young eagles remain with their parents until winter, but I would say rather that the month of October is the time they usually separate; they may then often be seen perched on some tree or on some rock, and permit of a comparatively near approach. S. G.

MATHEMATICS OF THE ARMAMENTS RACE

Generalized Foreign Politics
A Study in Group Psychology. By Dr. Lewis F. Richardson. (*British Journal of Psychology*, Monograph Supplements, 23.) Pp. viii+91. (Cambridge: At the University Press, 1939.) 8*s*. 6*d*. net.

THE application of mathematics to group phenomena such as those of the kinetic theory of gases and statistical mechanics has long been accepted by physicists. The extension of such methods to biology, economics, and psychology is also widely accepted. Dr. L. F. Richardson, who is well known for his work in physics and meteorology, but who also holds a degree in psychology, makes the daring attempt to deal mathematically with foreign politics, particularly with the growth of armaments and the motives which produce this growth. The author's method is to take a verbal argument of a leading statesman and replace it by differential equations. Thus, Sir Edward Grey said: "The increase of armaments that is intended in each nation to produce . . . a sense of security, does not produce these effects. On the contrary, it produces a consciousness of the strength of other nations and a sense of fear." This statement is replaced by a pair of differential equations, the meaning of which is certainly not exactly the same as that of the original statement. The differential equations really assert that for two nations, the rate of increase of expenditure on armaments by either is directly proportional to the total expenditure on armaments by the other. This variation of Grey's words is adopted because it is easy to deal with mathematically. However, it is immediately corrected by adding other terms, with a negative sign, to represent the restraining influence due to the burden of expense and fatigue, an influence not mentioned by Grey. The next step is to take account of an objection by Mr. Amery: "It was . . . in those insoluble conflicts of ambition and not in the armaments themselves that the cause of the War lay." An additional positive constant term is added to each equation to represent the extra rate of growth of the armament burden due to national grievances or ambitions.

Having set up the differential equations, it remains to solve them, and then to give the political interpretation of the solution. The exact solution offers no difficulty to mathematicians or mathematical physicists, as the equations are of a well-known type. Curiously enough, somewhat similar equations occur in a paper on "The Ignition of Explosive Gases". To meet the needs of those without much knowledge of mathematics, Dr. Richardson gives also a simple graphical treatment, which is similar to Marshall's diagram for the economics of international trade. In both the mathematical and the graphical treatment, the most important part of the work is to find out in what conditions the solutions become infinite. An infinite cost of armaments is interpreted as denoting war, though it might have seemed more natural to have taken it as bankruptcy. The final conclusions are difficult to state accurately in concise form, but they are roughly that there is a general tendency for peace to be unstable. This instability can be reduced by removing grievances, decreasing threats, and increasing international trade and other forms of co-operation. It is emphasized that increase of armaments, though undertaken as a measure of defence, tends to lead to war.

Opinions will differ as to the validity of this reasoning. Some may think that the author has made the first rough approximations in a new branch of science, which can be polished and corrected later. The mathematician, who knows that a small change in a differential equation can sometimes produce a large change in the solution, may be distrustful of the way in which the fundamental equations were obtained. Students of human affairs will assert, perhaps too hastily, that foreign politics cannot possibly be treated mathematically. However, the subtitle of the monograph is "A Study in Group Psychology", and possibly the method may be valid so far as the effects are entirely due to the group mind, to which a kind of statistical mechanics may be expected to apply. The author gives a numerical test of his theory for the years 1909–14, and it seems to accord closely with the facts for that period. One great defect is that the theory does not include the effect of "intelligent aggression planned by a leader as moves in a game of chess". Unfortunately, this is the aspect of the question which is of vital interest to millions to-day. H. T. H. PIAGGIO.

FILM REACTIONS AS A NEW APPROACH TO BIOLOGY*

By Prof. Eric K. Rideal, M.B.E., F.R.S.,
University, Cambridge

TOWARDS the end of the last century the biologist and physiologist were agreed that the biological entity was the whole living unit. This century has seen an attack on biological problems by the physical and organic chemist. The study of the living unit has been dropped, and in its place we find investigations on specialized processes such as oxidation and reduction or catalytic reactions. It is an unfortunate fact, as the late Sir William Hardy clearly pointed out, that in this method of approach the mechanism of the co-ordination or the integration of the activities of an assemblage of cells must remain insoluble. It is this very point which I think deserves some consideration. We must conclude that the mechanism of integration is at any rate dependent on a pre-existing organization of at least the major operative portions of the assemblage of cells. This raises a number of important problems such as: what types of organization are to be found in living material; how far control over chemical reactions can be effected by modification of the type or extent of such organization; and again how far different types of organization can modify such important factors as the chemical or physical state of a material or chemical equilibria in reacting systems; and lastly, what new properties or reactions make their appearance as a direct result of organization.

Whilst it has been frequently stated that one of the chief characteristics of living matter is that it contains a relatively large proportion of matter in what we designate the colloidal state, a closer analysis indicates that in fact the colloidal properties of living matter are due to the fact that an exceptionally large fraction both of material and of energy is present in films, membranes, fibres, fine capillaries and the like. It thus seems pertinent to inquire a little into the properties of surfaces of separation between bulk phases or of matter in the boundary state. These surfaces of separation can be considered as a new phase—the interphase—and for our discussion we must examine this phase and find in what respect it differs from the enclosing bulk phases.

While we must pay attention to the static properties such as composition, form and orientation, we must not forget that it is the dynamic properties of ingress and egress, of flow and chemical action in and with the two-dimensional contents of the phase, that we are particularly interested in, but any integrating features of the former are of great importance if it can be shown that they produce effects in the dynamics of the system which are not to be found in non-structural liquid or vaporous phases.

We already know that the composition of the interphase differs from that of either of the bulk phases in contact with it, and the general principles governing relationship between its composition and its three-dimensional partners were clearly enumerated by Willard Gibbs and Sir J. J. Thomson. Equally important are the considerations of Sir William Hardy and Irving Langmuir, who showed that in many cases when dealing with an interphase we were actually examining a monolayer—a hypothesis suggested by Lord Rayleigh. Finally, we know the molecules contained in the monolayer are orientated with respect to one another and to the plane of the interphase.

We have referred to the fact that molecules in a monolayer are orientated relative to one another and to the substrate and that this orientation can be altered by extension or compression. If the molecules in the monolayer undergo reaction with a reactant dissolved in the substrate, the rate of reaction may be modified by the charge in molecular orientation of the former. This is equivalent to a control of the steric factor and determining the path of approach of a reacting molecule or ion to the reactive portion of the other reactant. In this way both the reaction velocity and the height of the energy barrier or apparent energy of activation may be altered.

In the following table is given an example of such a variation in reaction effected by change in compression of a monolayer.

Attack on Lecithin Monolayers by 0·001 per cent Black Tiger Snake Venom at 20° and pH 7·2.

No. of lecithin molecules per sq. cm. × 10^{-14}	Half-life in minutes.
1·04	0·5
1·27	4
1·67	32
2·11	90

It is interesting to observe that these film reactions can be carried out with minute concentrations of strongly adsorbed reactants. Thus in the case of the attack of lecithin by snake venom to form lysolecithin, a half-life of about one hour is obtained with a concentration of venom as low as $2 \cdot 5 \times 10^{-6}$ per cent. When cobra venom is examined by this method, it is found that only in extreme dilutions does any reaction occur. This inhibition at higher concentrations is due to proteins present in the cobra venom which are absorbed in preference to the enzyme by the lecithin monolayer. Egg albumin, although not so effective when added to black tiger venom, will produce a similar result. In addition to lecithinase present in snake venoms, other enzymes have been studied, and among them crystalline trypsin and crystalline pepsin, which rapidly digest monolayers of caseinogen, the former at *p*H 8 and the latter at *p*H 2. When the purified and crystalline enzyme preparations are employed, these enzyme actions on the protein monolayers behave exactly as in bulk phase, although the protein has undergone a process akin to denaturation. With unpurified proteolytic ferments, on the other hand, fatty acid protein complexes are invariably present which give rise to other phenomena.

---

* From the presidential address to Section B (Chemistry) of the British Association, delivered at Dundee on August

In the reactions which we have discussed, the chemical processes involved do not differ from those which would occur in similar systems in the disorganized state and the only effects of molecular organization into orientated monolayers are noted in the alterations produced in accessibility of the groups as revealed by the rapidity of the reactions and in the apparent energies of activation.

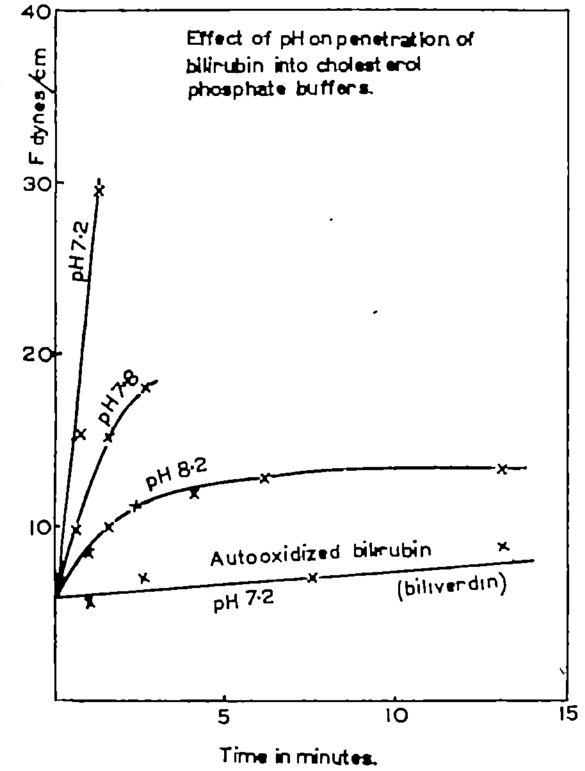
A further consequence of molecular orientation at interphases is found in those cases where radiation incident on the surface produces photochemical action after absorption of quanta by chromophoric groups in the monolayer. If, as is the case in ring compounds, the extinction coefficients are different along the three molecular or group axes, the photochemical reaction rate can be varied by alteration of the orientation by compression. Thus the rate of photochemical hydrolytic fission followed by oxidation in protein monolayers at those points along the chain where the chromophoric groups are situate can be varied within wide limits by simple expansion or contraction.

There are several processes in which an alteration in the properties of an interphase bring about a number of varied biological processes of great importance. I may mention the phenomena of lysis, agglutination, sensitization and the lethal activities of certain substances on various types of cells and micro-organisms.

Whilst the extent of mutual miscibility of two liquid phases is usually interpreted in terms of the relative internal pressures of the two liquids, we note from the molecular point of view, especially in the case of the large complex and the biologically important material, that we are really concerned with specific molecular interactions which may be identified as being due to those forces operative between the non-polar and the polar portions of the molecules respectively. In two-component monolayers the two molecular species are adlineated in respect to one another, and we should thus anticipate that it might be possible to form relatively stable two-component complexes which in three dimensions would only be detectable in terms of mutual solubility, and when a mutual solvent was present as a third component might not be observable at all. These conclusions are indeed fully borne out by investigations on two-component monolayers. It is found, for example, that strong complexes are formed in mixed monolayers of a variety of substances such as saponin with cholesterol or digitonin, or cetyl amine or sulphate with cholesterol.

Examination of a great variety of these systems has demonstrated that the free energy of formation of the complex is constitutive in the sense that its magnitude is dependent on the extent of interaction between the polar reactive groups and also that of the van der Waals interaction between the non-polar portions of the reacting species. The difference in properties of mixed films containing cholesterol on one hand and those containing, for example, epi-cholesterol is most marked, but when models are made of the two molecular systems, it becomes quite evident that the ease of adlineation of the hydrophobic portions of the molecule and the relative orientation of the polar group with respect to the axis of the molecule are the determining factors. The free energy changes involved in formation of these two-dimensional complexes are of the order of some 10,000 cal. per gm. mol. Complexes containing the constituents in ratios other than one to one can be prepared; thus cetyl alcohol and cetyl sulphate can form both a 1 : 1 and a somewhat unstable complex in the ratio of 1 : 3, whereas elaidyl alcohol produces an unstable 1 : 2 but no 1 : 3 complex. It is probable that with a more extended investigation of these interesting systems the basis for the most elementary form, that is, a two-dimensional crystallography of the type envisaged by Patterson, may be laid down.

I might mention in passing that the effects of cis-transisomerism on the free energies of the complexes are very characteristic and fully confirm the hypothesis we have advanced as to the importance of molecular adlineation; thus saturated aliphatic hydrocarbon chains with different reacting polar groups will form stable systems, likewise trans-olefinic chains can penetrate and pack both with one another and with saturated chains, but the cis- form is not capable of such adlineation. From the biological point of view, I think that the most interesting property of these systems lies in the mechanism of their formation, for on injection of one of the reactants beneath a monolayer of the other, it is found that penetration of the latter by the former will take place to form the complex monolayer. This penetration, if carried out at constant area, naturally involves a rise in the two-dimensional pressure, or if at constant pressure a rise in area is involved. We have indeed examined the formation of complexes under both these conditions, and the changes involved are frequently remarkable. Thus the injection of a few mgm. of saponin under a film of cholesterol compressed to a pressure of 10 dynes/cm. will cause an increase of pressure of more than 50 dynes/cm.; whilst a film of cetyl alcohol at 20 A.^{2} per molecule expands to no less than 78 A.^{2}, even when the pressure is maintained at 23 dynes/cm. on the injection of only 1 mgm. in 300 c.c. of cetyl sulphate.



In some cases a small alteration in the pH of the substrate may affect the ease of penetration of a reactant to a marked extent. In the accompanying diagram is shown the effect of such a variation on the rate and extent of penetration of bilirubin into cholesterol as a function of the pH.

It is possible to examine the reactivity of various substances in respect to penetration of monolayers. I have referred to the penetration of monolayers of cholesterol, and we note that some substances such as digitonin or cetyl sulphate or amine possess this property to a remarkable extent. Of the other important cell wall constituents we include phospholipins and the proteins. Little information as yet is available on phospholipins, but our knowledge of the reactions of this type in the case of the proteins, especially the alcohol-soluble and thus readily dispersible protein gliadin, has been greatly extended in recent years.

The stability of the protein monolayers is, as we have seen, due partly to their mutual association; if these are broken down by stronger associating reactants we might anticipate a dispersion of the monolayer resulting in a solution of the protein in the form of a protein-reactant complex. This phenomenon is readily observed on injection of even minute quantities of such substances as sodium oleate, cetyl sulphate, or psychosin beneath a protein monolayer.

Other substances may react by penetration into the protein layer but not effect dispersion. By spreading monolayers with various head groups and examining the reactions caused on injection, it is possible to identify the reacting group in the protein monolayer. A characteristic group of protein complexes formed in monolayers is the lipo proteins; thus gliadin forms a remarkable complex with cholesterol in the ratio 4 : 1 by weight. Here the cholesterol is anchored to specific groups in the gliadin, in particular the amino and carboxylic groups. At high pressures (20 dynes) the cholesterol is forced up above the protein monolayer and the surface becomes one essentially of cholesterol. Nevertheless the cholesterol is still anchored to specific portions of the protein, for on release of the pressure the lipoprotein film is re-formed. This extrusion and re-forming process can be repeated several times before the complex structure breaks down. It is interesting to note that saponin, which penetrates cholesterol with extreme ease, but proteins only slightly, will penetrate these lipo-protein films except at those pressures where the cholesterol is separated from the substrate by the protein monolayer to which the cholesterol is anchored.

It thus appears not unlikely that the materials such as cytoplasm, and especially in the more stratified chloroplasts, must be regarded as a protein gel framework to which is attached the enzymes, the phosphatides and lipoids, and the means of attachment is as we have seen due to the interaction both of the non-polar as well as of the polar portions of the molecules concerned. Another important conclusion to be drawn from monolayer experiments is that these penetrative reactions involve not only a new head group interaction, but in many cases also the breaking of such a head group interaction already existing in the monolayer prior to penetration. Several biological analogies may be mentioned. Thus, since lysis of blood cells can be brought about both by protein and cholesterol penetrants, we must conclude that it has lipo-protein surface. Several micro-organisms can be sensitized for lysis by cholesterol penetrants by a prior treatment with cholesterol. Again, cilia of Mytilus appear to be mainly lipoidal, those of Paramecia chiefly protein, as judged by the criterion of penetration.

The carrier action of desoxycholic acid on fatty acids can readily be demonstrated in monolayers, as desoxycholic acid does not interact with other lipoids, nor to any great extent with proteins. We find also that the hæmolytic activity of a long-chain alcohol is negligibly small owing to the fact that it is practically insoluble in water; but it readily forms a soluble complex with a long-chain sulphate and can be transported to the cell wall in this form. There both the sulphate and the alcohol can penetrate separately, the former acting both on the protein and on the lipoid, the latter only on the protein, and produce lysis.

Yet another reaction of this type has been described by Peters and Wakelin, who found that the complex ovoverdin containing protein and astacin could be split to form a lipo-protein containing soap by the addition of small amounts of saturated long-chain fatty acids setting free the astacin. On the addition of calcium ions the process is reversed. They likewise direct attention to the fact that it seems probable that the co-enzyme in an oxidase system may be separated from the enzyme by the formation of such a lipo-protein complex.

Somewhat more complex in behaviour are the blood coagulants, heparin and the synthetic sulphate celluloses. It is found that their biological activities run parallel to the ease with which they penetrate films of cholesterol. It is not unlikely that they operate by breaking down a cholesterol cephalin complex, setting the latter free.

We have referred to the fact that, for the penetration of a monolayer by a substance injected into the substrate, primary interaction between the reactive head groups occurs, followed by solution, that is, penetration and adlineation, of the tail. In the case of reactants containing two or more reactive head groups, it is found that these can associate with head groups in the monolayer and thus form a series of links. Here another important factor is found operative. If the injected bipolar molecule possess a hydrophobic portion of such a structure that it can pack or adlineate with its neighbours beneath the monolayer, the resultant composite film is remarkably stable. Thus the long-chain dibasic acids are adsorbed on to, but do not penetrate, monolayers of amines, whilst the diamidines are adsorbed by, but do not penetrate, monolayers of cholesterol. Substances containing the phenolic group are of particular interest in this respect, as they include a number of biologically important substances. They react with amine groups quite readily, and to a less extent, with the imido group in a polypeptide chain. Gallic and tannic acids react with great ease with monolayers both of amines and with proteins. It is interesting to note that the reactivity of tannic acid with the spaced amine groups of the protein is high, and that subsequent injection of fatty acids beneath such treated monolayers results in the dispersion of the galloylamine or galloyl-protein complex film, but not in the tanned one—an indication of the effectiveness of the interlinkage produced in the non-dispersible network by the multiple point contact of the large tannic acid molecules.

Another significant biological similarity has been noted when we measure the extent of penetration of a series of substances containing identical hydrophobic 'tails,' for example a C_{12} chain, but with different head groups, into a monolayer of a typical lipoid such as cholesterol. In all cases the extent of interaction as measured by the increase in surface pressure caused by the injection of 0·33 mgm./100 c.c. under a film of cholesterol originally extended to 40 A.^{2} per molecule is found to be closely parallel to the hæmolytic activities and lethal activities on Paramecia of these substances.

These latter can be placed in order both of monolayer penetration and biological activity:

$$RNH_3^+ > RSO_4' > RSO_3' > RCOO' > RN(\overset{+}{C}H_3)_3 > RNH(\overset{+}{C}H_3)_2 > \text{bile acids.}$$

We may conclude that the most reactive group in the protein macromolecule is the amino group, since the —NH—CO— group is poorly reactive, a point of some interest when we examine the reactions of lecithin and of cephalin. This order of head group reactivity receives confirmation when penetration into monolayers containing these head groups is examined, that is, on inverting the system. When we compare the reactivities of a series of long-chain compounds with identical head groups, it is found that biological activity and film penetration commences with C_8 when attached to a very reactive head group, with C_{12} when attached to a poorly reactive group, and reaches a maximum value at *c.* C_{16}. It is interesting to note that it is not necessary for all the carbon atoms to be in the form of a chain but that they may be enclosed in rings; thus activity commences with diphenyl derivatives and increases with addition of carbon atoms to an optimum, as in the bile acids, stearic acid, diethyl stilbene and benzpyrene. By examining the reactivity of substances containing two reactive groups at various spacings underneath protein monolayers, it is possible to obtain some idea as to the statistical distribution of the reactive groups in the monolayer. It would appear that some 12·5 A. is the mean distribution of the amine groups beneath a gliadin film. In the native protein such spacings are naturally different, and thus reactions involving two-point contact will not take place in bulk phase unless the spacing is unaffected by two-dimensional unrolling of the protein.

We have referred to the modification which must be introduced into either the Overton Meyer or Traube concepts of biological activity, that is, lipoid solubility or capillary activity necessitated by the concept of specific head group interaction. We see that a definite limit is also set to the hydrophobic portion of the molecule, not only on account of the decreasing solubility in the aqueous phase causing difficulty in transport, and on account of the ease of adlineation or packing having an optimum of C_{16} for association with sterols or fats, but also because a new phenomenon sets in with long chains, namely, dispersion of the monolayer. It is possible that this phenomenon of film collapse and dispersion may be a generally important factor in setting the upper limit to the chain length, or more generally the capillary activity of homogeneous series of biologically important substances, for example, anæsthetics. This dispersion of protein films may have biological counterparts in adsorption on specific portions of the cell surface similar to the hæmolytic activity of long-chain compounds such as oleic acid, which readily disperses protein films.

This method of attack permits us to investigate the nature of the coatings of cells or unicellular animals and plants by examining the effects of lipoid or protein penetrating substances on them.

Thus both red cells and Paramecia are affected by both lipoid and protein monolayer penetrating (cytolysing) or adsorbing (agglutinating) agents, and we deduce that their surface structures must contain lipoproteins or consist of a lipoid protein mosaic; whereas certain other unicellular animals frequently found associated with Paramecia and in addition the cilia of Mytilus are not affected by protein dispersants but are readily influenced by lipoid penetrating agents, and their coatings in consequence must be chiefly lipoidal in nature.

Examination of the carcinogenic hydrocarbons by the monolayer technique reveals the interesting fact that, whilst they themselves are unreactive, they are readily converted into extremely reactive water-soluble photo-oxides. These substances are not only reactive to protein monolayers like the water-soluble dibenzanthracene endosuccinate, but also are paramecicidal, the parallelism between the biological activity and monolayer reaction being maintained.

It has been the purpose of this address to re-emphasize the importance of the fundamental concepts introduced by Sir William Hardy and Dr. I. Langmuir as to the structure of matter in the boundary state. I have attempted to show that there is implicitly contained in the concept of molecular orientation a whole series of properties and events for which there are no analogies in homogeneous bulk phase systems. We note that many of the modes and types of the reactions which can be effected in monolayers, and which can be defined with precision and their mechanism established with a considerable degree of assurance, are unique for such interphases, but are again observed in living and organized material. It is with this object of ultimate correlation with biological behaviour that we have taken up the detailed study of interfacial reactions at Cambridge, and I should like to express my indebtedness to Dr. J. Schulman, who has been associated with me in this object.

Many 'vitalistic' models have been proposed in the past, and whilst it might be correct, although unscientific, to suggest that the ultimate level of integration in living matter is incapable of examination and definition, yet I believe that one is justified in asserting that at least one of the important levels to which due attention must be given for a proper understanding of biological activities is that of the ordered interface.

CULTURAL SIGNIFICANCE OF ANTHROPOLOGICAL STUDIES*

By Prof. H. J. Fleure, F.R.S.,

University of Manchester

THE vision of a universe in evolution has shown men that what had been accepted as absolutes are in several cases by-products of evolution. Old beliefs are increasingly relegated to the domain of folklore survivals, and the effects of this upon motive power in personal and social conduct are major factors of the present crisis in world affairs. Having been so long accustomed to accept an absolute basis which has now been undermined, men have hastily sought a new absolute, and some think they have found it in the State, which is being made an object of worship. This growth of State worship has come earlier on the Continent than in Britain, for we have pursued our traditional policy of finding a compromise that postpones the crises due to insoluble problems. Evangelical and tractarian movements have had influences of this kind on British life; they have counted for much less on the Continent. Again, State worship has grown with the acceleration of production and communications, a process that has given rise to an uncomfortable feeling of jostling and trade-pressure. We have attained to an anarchy of sovereign States and understand one another too little.

---

* Prepared for a discussion on "Anthropology in Education" arranged by Section H (Anthropology) for the Dundee Meeting of the British Association.

To study the peoples of the world in process of evolution in their varied environments is thus one of the greatest needs of our time. Men and women, their physical characteristics and functions, their social organization and material equipment, their reproductive rates and all that is linked with this, interrelations of groups, including production and exchange of commodities and ideas, their systems of control and the clashes thence arising, all need deeper interpretation for all peoples of the world, from the pigmies of the equatorial forest to the citizens of the United States of North America.

Specialists have taken up studies in physical anthropology, in social organization especially of the illiterate peoples, in archæology, in human geography and so on. But the difficulty has arisen that these subjects are too separate to allow a sufficient number of those who follow some of them to find opportunities to teach them in such a way as to make them a feature of a general education. So long as they remain pure specialisms, they must have small followings. We need a co-operative scheme that will bring them together, not as one 'subject', but rather as a linked group.

The human geographer, seeking to elucidate relations between men and environment, will study situation, climate in its relation with vegetation, and the annual cycle of cultivation, and this should lead on to the discussion of the round of festivals and ceremonies that marks the agricultural year. Here the social anthropologist dovetails with his appreciation of those rites and ceremonies his understanding of the fact that both these and the agricultural processes they accompany are not results of direct planning but rather the product of ages of 'trial and error'. This undeliberate method has been man's chief tool through the ages; the reason has come in to correct misapprehensions and wrong sequences of argument. The human geographer, again, will try to understand land-tenure and will appreciate the fact that better watered patches in an arid area are likely to have a scheme of tenure different from that used in areas of equatorial forest.

The anthropologist will then come in and study schemes of inheritance and control of land, and so one might go on and show how human geography and anthropology combine. The more they are studied together the better will it be for both subjects, for both their research and their educational aspects. They may co-operate with special advantage in studying the changes of land tenure, agriculture, organization and government among African peoples who have come into contact with Europeans. Intertropical Africa produced very little for export sixty years ago; recently its export trade approached one hundred million pounds sterling per annum. This change has had many repercussions on every part of a social structure that had been built up on subsistence agriculture and the almost completely self-supplying village. An analogous change from local self-sufficiency to complex interdependence has been going on among the peasantry of Europe in the last hundred years, and this is part of the problem of clashing national sovereignties that is threatening ruin to us all.

During the last twenty years, archæologists have realized, to a greater extent perhaps than social anthropologists, the need for studying environment. Concurrent studies of climate change, recently assisted by work on pollen analysis, and of soils, have shown increasingly that environments have undergone extensive changes within the period of human history and that reconstructions of environments of the past should be reconstructions for the climatic and vegetative conditions of a specified period. It has also been increasingly realized that prehistoric archæology tells us about our own ancestors, not about exterminated and forgotten peoples, and this has been an important factor in making archæology a study of the evolution of the future from the past.

At the same time, there is increased objection to accepting old parallels between peoples of antiquity and peoples of to-day. It is now considered less than a half-truth to say that the Australian blackfellows are surviving Mousterians, or the Bushmen of South West Africa surviving Aurignacians. Some of the Aurignacians were the leading peoples of their day and were on the upgrade; the Bushmen are rather a lingering remnant. Bushmen and Australians have picked up fragments of more advanced cultures even if, in some cases, these fragments are barely half-digested.

Physical anthropology, greatly helped by modern views of heredity, is learning to treat mass statistics with reserve and to criticize schemes of classification. Head form and pigmentation, for example, have very different kinds of histories. Depigmentation has affected a number of elements of differing bony structure in north-west Europe, and the idea of a unified Nordic race belonging basically to the Baltic is almost as fantastic as the twin-fancy that this Nordic race developed the essentials of European civilization and spread them from this assumed early home.

My plea is that a group of linked humane studies based on direct observation and measurement is needed not only for specialist work but also at all stages of education, and that the group should include human geography, social anthropology, physical anthropology and archæology, though it is obvious that one can scarcely expect any one person to cover all these specialisms. All that is needed is that they should have some common ground.

OBITUARIES

Prof. R. S. Troup, C.M.G., C.I.E., F.R.S.

THE death of Prof. R. S. Troup on October 1, at the age of sixty-four years, removes one of the outstanding figures in the development of forestry in the Empire. He passed the competitive examination into the Royal Indian Engineering College at Coopers Hill in 1894, and ever since then his profession had been his predominant interest. Endowed with more than the usual amount of Scottish common sense and with a good deal of Aberdonian caution, his mentality was peculiarly adapted to the orderly collection and presentation of facts.

After a brilliant career at Coopers Hill, where he took a number of prizes, not only among the few forest students, but also in competition with the far more numerous students of the engineering side, in such subjects as geology and surveying, Troup went to Burma with the other four men of his year. There he started with practical experience in some of the finest and best managed forests of the Empire. His reputation had preceded him and after a few years he was called to Dehra Dun, then beginning to assume its position as the headquarters of the Indian Forest Service. From about 1904 until 1920, when he left India, he was engaged in research and administrative and scholastic work, as a teacher at the Forest College, as forest economist, as sylviculturist, and finally as assistant inspector general of forests to the Government of India. These posts gave him unique opportunities not only of seeing all the finest forests in the quarter of a million square mile forest estate of the Indian Empire, but also of gaining an accurate knowledge of how this magnificent property could and should benefit the population.

Troup's own interests lay more in scientific sylviculture than in the utilization side, but his early training ensured that he should fully recognize that first-class sylviculture is not an end in itself but, to put it briefly, a means of obtaining the largest volume of the finest timber on a given area. Apart from a number of publications on the uses of woods and allied subjects, the principal works which he produced during his service in India were "The Silviculture of Indian Trees" in three fine volumes and "A Note on some European Sylvicultural Systems with Suggestions for Improvements in Indian Forest Management". This latter work, "the outcome of a tour made in 1913 in certain selected forests of France and Germany", appeared in 1916, and has always seemed to the writer to be of outstanding interest. Illustrated by excellent and well-chosen photographs, a clear and vivid description is given of all the important sylvicultural systems employed on the continent of Europe, and the possibility of their adaptation to the very different conditions of India and Burma is fully discussed. "Silvicultural Systems", which was published by the Clarendon Press in 1928, is an up-to-date and more generalized study of the same kind. It has been praised by Continental experts as being better than anything they have. In the work of 1916, Troup gave evidence of a very broad and catholic outlook on the main problems of Indian forestry, and established the principles on which the most important measures of progress have been based during the last twenty-five years.

Troup's greatest work, "The Silviculture of Indian Trees", appeared in 1921 and is, in his own words, "the outcome of several years of research into silvicultural problems at the Forest Research Institute, Dehra Dun, and at outlying experimental stations, combined with observations recorded in many parts of India and Burma for a period extending over twenty years". The writer, having accompanied Troup on many occasions in the field, can confirm the care with which these observations were made and recorded, and can testify to the technical interest of the scholarly descriptions of the very varied types of forests in India and Burma and to the great value of the estimates of the sylvicultural needs of the more important species. Constant use has been made by Indian forest officers of the information stored in these volumes, which have become standard works of reference, and contain much that was not available before.

After leaving India to succeed Sir William Schlich as professor of forestry at Oxford, Troup's interests gradually changed, and, as the result of a number of tours to various parts of the Empire, particularly Africa, he became recognized as an authority on forestry in the Colonies, and was, at the time of his death, engaged on a work on Colonial forest administration. His last publication, in 1938, was a small volume on "Forestry and State Control", which reviews the position in all the more important forest countries of Europe, with particular reference to the urgent need for improving the private forests of Great Britain.

His devotion to his profession and his remarkable ability in summarizing clearly and fully the salient points of any forestry problem earned for Troup a unique position, and made him a worthy successor to the great men of the earlier years of Indian forestry. He was also a good 'jungle man' with a proper appreciation of life in wild places, with a keen interest in the forest flora and fauna, and, in his younger days, a great love of sport. He was a successful 'shikari' and a very good shot.

ALEXANDER RODGER.

Prof. Ricardo Jorge

PROF. RICARDO JORGE, an eminent Portuguese hygienist and medical historian, was born on May 22, 1858, at Oporto, where he received his medical education and carried out some important work on plague in conjunction with Dr. Camara Pestana. He afterwards went to Lisbon, where he was appointed director-general of public health and professor of hygiene.

In 1912 Prof. Jorge was made the delegate for Portugal in the International Office of Public Health in Paris, where he was a regular attendant at its meetings and contributed important papers to its proceedings until shortly before his death. His published work comprised a large number of subjects, such as undulant fever, tuberculosis, pellagra, lethargic encephalitis and its mental sequels, alastrim, post-vaccinial encephalitis, epidemics on ships, especially the typhoid form of malaria and dengue, spirochætal jaundice, influenza and epidemic pleurodynia. As medical historian, he took an active part in the proceedings of the International Society of the History of Medicine, to which he contributed scholarly articles on the epidemics of the sixteenth century, the Renaissance in anatomy and medicine in Portugal, medical and scientific relations between England and Portugal and plague epidemics in Europe.

In addition to his medical activities, Prof. Jorge took a keen interest in literature, art, history, philosophy and philology, so that he has often been compared to the humanists of the Renaissance. He counted many friends in Great Britain, where he was elected an honorary fellow of the Royal Society of Medicine in 1938, twelve years after he had been made an honorary member of the Section of Epidemiology. One of his last writings was a sympathetic obituary notice of Sir George Buchanan, his colleague at the International Office of Public Health. His death took place on July 31 at the age of eighty-one years.

J. D. ROLLESTON.

WE regret to announce the following deaths:

Sir William Pope, K.B.E., F.R.S., professor of chemistry in the University of Cambridge, on October 17, aged sixty-nine years.

Dr. W. B. Wright, late of the Geological Survey of Great Britain, author of "The Quaternary Ice Age", on October 11, aged sixty-three years.

NEWS AND VIEWS

Ministry of Information

THE debate in the House of Commons last week on the Ministry of Information was announced too late for account to be taken of it in the leading article on the suggested Directorate of Scientific Information in NATURE of October 14, but there appears to have been nothing said which invalidates the comments in that article; indeed, the debate rather served to emphasize the importance of the principal points. Replying on behalf of the Government, Sir Samuel Hoare admitted that the public had lost confidence in the Ministry, and outlined the steps taken for its reorganization. Two factors have no doubt contributed largely to the difficulties of the Ministry, namely, confusion between the task of collecting information and of disseminating it, and the failure to utilize effectively organizations already in existence. The first has involved the Ministry in the difficult question of censorship and authority in relation to other Departments of State; the second has been responsible for excesses of expenditure and lapses of judgment for which the Ministry has been rightly criticized. It is not always realized that the collection of information in itself is a specialized activity. In the technical and scientific sense it is the task of the numerous information bureaux or departments, such as various Imperial Agricultural Bureaux, those associated with different research and other associations or with individual industrial firms. Activities of this kind are to be found over the whole range of industry and science, including the social sciences. To some extent the Association of Special Libraries and Information Bureaux serves as a clearing house in this field, and its services have already been offered to the Government. Official recognition of the vital necessity of information services and their co-ordination does not as yet appear to have been forthcoming, nor has their utilization by Government Departments and other organizations concerned with national service been encouraged, a situation which would scarcely have arisen had the Ministry been provided with adequate scientific guidance.

The collection of more general information in the sense of news is the essential task of the journalist, and some of the severest criticism of the Ministry of Information has been based on its neglect of the unrivalled experience and organization of the daily Press, both in the collection of news and in the problems involved in handling it. The statement hat news and censorship will now, generally speak-ng, be separated from the Ministry of Information, nay make such criticism irrelevant so far as the inistry is concerned, but the Government would lo well to take the lesson to heart, for other departnents also have tended to make the mistake of ormulating complete plans of their own instead of naking the utmost use from the start of existing rganizations and facilities. The collection of informaion is one activity demanding a particular technique nd type of mind; the dissemination of information s another activity and may require entirely different gifts. Incidentally, most information departments re concerned with both these activities in that they ollect information for use. The first essentials in andling information are sound judgment and a clear nderstanding of the extent to which the use of a articular piece of information is to be limited, either n the general interests of the industry or organization hich an information department is serving or, as ith the Ministry of Information, of the national inerests in the widest sense. The work of the ablest inormation bureaux, however, can be seriously injured y departmentalism which is lacking in vision or a ense of proportion. Sir Edward Grigg, Parliamentary ecretary to the Ministry, was able to give a welcome ssurance that no effort would be spared by the inistry to see that the country preserved its right o know the truth about the war in which we are ngaged and its right to comment with absolute reedom on that truth.

eace Aims

The correspondence columns of the leading lay ournals have given ample evidence of the lively oncern felt by thoughtful men everywhere as to he ultimate goal towards which Great Britain and rance are striving through the present conflict. A oteworthy pronouncement in the form of a manifesto igned by no fewer than fifty-seven men of science, all f whom are fellows of the Royal Society, appears in he *Manchester Guardian* of October 13. The names f the signatories represent many branches of scientific vestigation, but in the covering letter sent with the anifesto and signed by the Bishop of Birmingham, ir Richard Gregory, Prof. Lancelot Hogben, Sir John rr, Prof. A. J. Clark and Sir Peter Chalmers Mitchell, is pointed out that they "do not claim to speak for eir scientific colleagues as a body". The manifesto oints out that the "progress of science and its pplication to human well-being are threatened by e prevailing anarchy of international relations", nd states that a new international order, going far eyond the provisions of the Covenant of the League f Nations in its claims on individual States, should e set up when the war ends. All nations prepared renounce war between themselves should be vited to unite under a federal Government, which ould have power to use armed force against aggreson, would control the raw materials of undeveloped rritories in the possession of member States, and ould undertake the education of backward comunities without racial discrimination. Although perience of the League of Nations shows that these provisions are bristling with practical difficulties, there will be general agreement that a new world order based upon them would command the support of a considerable body of informed opinion.

T. K. Penniman

The curatorship of the Pitt-Rivers Museum in the University of Oxford, which has been vacant since the death of Dr. Henry Balfour earlier in the year, has been filled by the appointment of Thomas Kenneth Penniman, the appointment being for a period of seven years dating from October 1, 1939. Mr. Penniman is a member of Trinity College, Oxford, and holds the diploma in anthropology of the University of Oxford. He is the secretary of the Board of Anthropological Studies in the University, and is the author of a history of the progress in anthropological studies in the last hundred years, which in its introductory chapters traces the beginnings of anthropological observation, the work thus being a complete survey of the development of the science. Mr. Penniman was also joint editor with Dr. R. R. Marett of the correspondence of the late Sir Baldwin Spencer, the distinguished authority on the primitive tribes of central and northern Australia.

Robert Henry Thurston (1839-1903)

On October 25, Cornell University will celebrate the centenary of the birth of Robert Henry Thurston, the distinguished American professor of engineering, who by his work at the Stevens Institute of Technology, Hoboken, and the Sibley College of Engineering, Cornell University, contributed more than any other man of his time to the advancement of engineering education in the United States. Thurston was a man of great force of character, but sympathetic, the friend of all his students, and he was possessed of a wide and generous outlook. With a remarkable memory, great powers of concentration and unceasing industry, he was not only a teacher and engineer, but also an original investigator, an expert, and a public servant. He published some 300 scientific and technical papers and twenty separate works. When engineering education was in its infancy he founded the first engineering laboratory in the United States, and he was the first to serve as president of the American Society of Mechanical Engineers.

Thurston was born at Providence, R.I., the son of Robert L. Thurston, one of the pioneers of steam engineering in America. At the age of sixteen he entered Brown University, and after graduating, went into his father's workshops. The Civil War saw him an assistant engineer in the U.S. Navy, and at its close, in 1865, he was made an assistant professor of natural philosophy at the Naval Academy, Annapolis. This, however, was but a stepping stone. On the inauguration in 1870 of the Stevens Institute of Technology, Hoboken, the president, Henry Morton, invited him to become professor of mechanical engineering. For fifteen years he laboured at Hoboken and then, in 1885, the trustees of the Cornell University asked him to undertake the organization and development of the Sibley College of Engineering. When he took charge the total attendances in all classes was about 60; at his death in 1903 the attendances were about 960. The teaching staff had grown from 7 to 43. Besides his work as a teacher, writer and experimentalist, Thurston served on various committees and was a member of numerous societies both at home and abroad. The gathering at Ithaca on October 25 will pay tribute to his memory, and will also discuss ways in which engineering may meet the crucial challenge of our rapidly changing world.

A National Atlas of Great Britain

THE report of the committee appointed by the British Association in 1938 to prepare a scheme for a projected National Atlas of Great Britain and Northern Ireland was presented to the Association at the Dundee meeting and contains provisional details of the format and contents of such an atlas. "The proposed atlas," the report runs, "aims at a strictly objective and scientific presentation of the natural conditions, natural resources and economic development of the land (and adjacent seas), of the history and pre-history of the country, and of the distributions, occupations, movement and social conditions of the population." To this very comprehensive programme the proviso must be added "in so far as they provide suitable material for cartographic exposition", since it is not intended that there shall be any accompanying text to the maps. Such a work necessarily involves the collaboration of scientific workers in very different fields, and six sections of the Association were represented on the reporting committee, which sat under the chairmanship of Prof. E. G. R. Taylor (Section E).

THE complete Atlas will be in two large folio volumes, each volume containing 60–70 plates. The number of maps will, of course, be many times greater than the number of plates, but the sheet size has been selected so as to show the whole of England and Wales at a single opening on the scale of one to a million, a scale which experience has shown to be appropriate for many types of general map. The maps are grouped under four general headings: physical geography, bio-geography, industry and commerce, and human geography. Under physical geography are included cartography, orography, geology (with geomorphology), climatology and hydrography. Under bio-geography the sub-headings are soil, vegetation, distribution of species, pre-history (of plants), land utilization, forestry and agriculture. Many of the maps will be of types not hitherto constructed, or at least not hitherto published for Great Britain. Such, for example, are maps dealing with health and disease, recreation and amenities, which fall within the human geography section, and maps of accessibility from and to the leading cities, in the section devoted to industry and commerce. For certain sections and sub-sections, the contents of individual maps are indicated in the report, the object being to ensure constructive criticism and co-operation from workers engaged in particular fields of research. As the report states, the success o the enterprise "must depend on scientific workers an scientific bodies willing to undertake responsibilit for the accuracy of maps within particular fields"

Contemporaries of the Mammoth

IN an article contributed to "Russia To-day Pres Service" (Sept. 12, 1939) Prof. P. Kapterev gives a account of his experiments with organisms containe in frozen soil from Siberia. A paper by Prof. Kaptere on his discoveries was read before the Academy o Sciences of the U.S.S.R. during 1936 (see NATURE 138, 714; 1936). The flora associated with th mammoth has been known for years from the content of the food canal of frozen individuals, but it i astounding to learn that plants and animals contemporary with the mammoth have been brought t life after remaining in a state of suspended animatio which at a low computation must have extended ove twenty thousand years. The soil from which th organisms were obtained consisted of silt strat obtained in the galleries of mines in the taiga c Siberia at a depth of 131¼ feet, far within the limi of the permanently frozen soil, for even in th hottest summer the thaw never penetrates deepe than seven to ten feet. In contemporary strata th explorers found the bones of mammoths, the wooll rhinoceros, bison, and musk-ox, indicating a perio contemporary with the interglacial period whic came between the last two Ice Ages (Riss-Würm period) or with the last Ice Age (Würm period). Th soil samples were placed in sterilized containers in sterilized atmosphere, and they eventually yielde living organisms which included several kinds of soi bacteria, including a distinctive nitrogen bacterium fungi and water plants, the majority being closel related to present-day forms. From another sampl of later geological date, taken at a depth of 14 feet twenty different kinds of water-plants, mosses, filaments of fungi and a crustacean (entomostracean were obtained, and placed in favourable laborator conditions these organisms began to multiply rapidly But this stratum is reckoned to have been only from one to three thousand years old!

Archæological Excavations in Northern Syria

MR. M. E. L. MALLOWAN's account of his furthe excavations in Northern Syria in the report of th British School of Archæology in Iraq (Gertrude Bel Memorial) for the year ended June 30, 1939, agai records a striking frequency in the occurrence o amulets of various kinds among the finds—a featur to which attention was directed in earlier report The report on Mr. Mallowan's work covers the fift expedition to Northern Syria and the third consecutive season's excavations at Brak, one of th largest of the mounds in this part of Syria. Th great mud-brick temple, which Mr. Mallowan ha named "The Temple of a Thousand Eyes" on accoun of the enormous number of alabaster "eye idols" found in the foundations of the platform on whic the temple is built, has so far produced the mo important discoveries of the expedition. Its dimensions are approximately 30 yards by 25 yards; and its walls are exceptionally heavy, the outer walls being more than eight feet thick. They are buttressed with rough blocks of limestone and basalt. The temple dates from about 3000 B.C. and is thus the oldest shrine yet discovered in eastern Syria. Its architectural relationship to archaic temples at Warka, about eight hundred miles down the Euphrates from Brak, points to cultural contacts between north-east Syria and Sumer at this early date. A striking feature of the plan of the temple is a central shrine, three times as long as it is wide, with a pedestal for the presiding god against the end wall.

The adornment of the temple would appear to have been remarkable. A magnificent frieze consisted of three separate panels on the three faces of the pedestal in the sanctuary. Each of these was three feet in length and eight inches in breadth, and was composed of outer bands of heavy gold foil encasing blue limestone, white marble, and green corrugated shale. The panels were fastened to a wooden background with copper holdfasts, while the gold borders were held down by gold-headed nails with silver stems. No panels of this kind have previously been discovered. One of them has been allocated to the British Museum. Fragments of fluted copper panelling, which had adorned the walls, have been discovered; while on the south side the wall was embellished with a mosaic of clay cones painted in bright colours, and surmounted by large stone rosettes with alternate petals of white marble and dark green shale and a central corolla of red limestone. In the material of the mud-brick platform on which the temple stood, many thousands of objects were found. These include many beautifully carved amulets—models of lions, rams, bears, monkeys and vultures in serpentine and bone. A number of human heads in alabaster are said to be landmarks in the history of sculpture. A summary of the report appeared in *The Times* of October 14.

Juvenile Delinquency

In a discussion on juvenile delinquency before the Royal Statistical Society on April 18 which has now appeared (*J. Roy. Statist. Soc.*, **102**, 384; 1939), Dr. Rhodes concludes that juvenile crime appears to be part of a major problem, including adult crime, which involves social and economic considerations. More exact information regarding the age-constitution of local populations is required to gauge properly the differences between the incidence of juvenile crime in different parts of the country. In considering changes with time, we must take account of changing environment if we are to deduce anything from the facts of recorded crime regarding changes in the naughtiness of the juvenile population. Mr. C. P. Hill agreed that juvenile delinquency was linked both with density of population and with unemployment, but considered there were so many other unknown variables to be taken into account that no accurate forecast was possible as to the probable future course of juvenile delinquency from the data available. Mr. J. H. Bagot, from Liverpool experience, stressed the wastage in probation and education offices and police departments through the non-use of statistics, and concluded that the vast proportion of the delinquents were drawn from one section of the population, and, within that section, from a defective group, either from the point of view of family or overcrowding.

Alcohol and Crime

In an important paper on the problem of alcohol and drug addiction in relation to crime, published in the October issue of the *British Journal of Inebriety*, Dr. W. Norwood East, formerly H.M. Commissioner of Prisons, discusses the relation of parental alcoholism and drug addiction to crime, alcoholism in the individual as a cause of crime, the medical and legal aspects of alcoholic crime, and the treatment of criminal alcoholics and drug addicts. He illustrates the insignificant part played by drug addiction as a cause of crime, at least in Great Britain, by the fact that in 1937, when the number of drug addicts known to the central authority was only 620, not more than 31 persons were dealt with under the Probation of Offenders Act, or fined or imprisoned for offences against the Dangerous Drugs Act. Dr. East further points out that while every practical criminologist will attach some importance to the association of alcoholism and crime, it is easy to over-emphasize the connexion, and in support of this contention brings forward statistics from various prisons showing that familial or individual alcoholism is a much less frequent cause of crime than was formerly supposed. While allowing that the general medical treatment of alcoholism and drug addiction may be supplemented by psychotherapy in suitable cases, Dr. East asserts that this method is apt to be disappointing, and that he does not know of any impressive series of figures illustrating the success of such treatment.

Future of Welding

It is now known that the substitution of fabrication for casting is very advantageous to heavy-machine makers in a number of ways, mainly because it obviates the necessity of pattern-making. The time that would otherwise be lost in the foundry is considerable, especially when new patterns have to be evolved. In a leader on welding in the *Electrical Review* of September 29, it is stated that many electrical and allied manufacturers are now using welding on a fairly large scale. Some of them go so far as to design and make their own welding equipment. There are on a conservative estimate about forty manufacturers of electric welding machines in Great Britain and there are nearly as many suppliers of rectifiers for welding and thermionic valve control devices. Besides, there are one or two factories which make holding frames for rotating or otherwise manipulating the welding work being done. It is probable that not more than about a quarter of the known applications of welding are utilized in industry. The large amount of research being done is shown in the second progress report of the Institute of Welding. Further evidence is given of the increased applications by the issue of official regulations and specifications for welded steelwork by national bodies in many countries. Some manufacturers think that the welding industry may ultimately employ as much capital and labour as the steel industry now does. Such considerations apply equally to shipyards, and remembering the inherent water, oil and gas tightness of welded vessels, the rate of advance in the use of welding in shipyards will doubtless advance more rapidly in the future. The progressive widening of applications is producing fresh problems. Large-scale operations indicate the desirability of carrying out as much as possible of the actual welding in specially devised workshops rather than at the shipbuilding berth. This requirement will sometimes entail the re-design of component sections to render them more transportable and also the provision of suitable and adequate manipulative and adequate lifting equipment.

Johannesburg Municipal Bus and Tram Sheds

The all-welded structure of the new municipal bus and tram sheds at Johannesburg is claimed to cover an area greater than that of any other welded structure in South Africa. In *Electric Welding* of August, it is stated that, excluding an office block of reinforced concrete, the building has a frontage of 465 feet and an area of approximately 186,000 square feet. The outer walls are of concrete but all the interior walls are steel-framed. The floor is of concrete throughout. To give unobstructed floor space, the number of columns was cut down to a minimum. The largest of the girders span 90 feet and are 12 feet deep. They were dispatched by road from the company's workshops at Benoni, where all the steelwork was fabricated. To allow of transportation through Johannesburg, they were split into halves, the halves being welded together at the site and the girders lifted in one piece. A striking feature of the design is the absence of gusset plates and the lightness of all the sections employed. The entire framework is welded, including even the site connexions. The saw-toothed type of roof employed produces excellent internal lighting. The percentage of windows to floor space is about thirty. The lamps provided are of the mercury vapour type. Between 500 and 600 tons of steel were used in the erection of the sheds, the greater portion of this steelwork being produced in South Africa.

Electric Lighting in a Modern Store

In Welwyn Garden City, Herts, an entirely new building now houses the Welwyn Stores; a description of the building is given in the *Electrical Review* of October 13. The Welwyn Electricity Supply Co. built and equipped a new sub-station near the site to meet the required demand. The G.E.C. Co., Ltd., installed the whole of the lighting and fittings for 336 combined tungsten and Osira lamps, The outside illumination consists of four large neon signs. The shop fronts have artificial stone piers, marble risers and a painted wooden facia and cornice in which is set a line of fluorescent tubing running round three sides of the building. About 900 feet of 'Clora' coated tubing has been used for this purpose. The store itself comprises ground floor and part of the first floor. Under an artificial daylight effect achieved by 'T.O.T.' units, the natural wax-polished oak counters, stock fittings and panelling show up well. During the daytime, the daylight entering the ground floor through 'glass-crete' rooflights from the staircase blends with the artificial illumination, all strong contrasts being eliminated. Each lighting unit consists of one 80-watt 'Osira' fluorescent type discharge lamp and three 150-watt tungsten lamps enclosed in opal sphere pendants 18-in. in diameter. All the main selling floors have this type of lighting. The food hall is a separate section on the ground floor. There are 1,400 feet of fluorescent tubing, arranged round the ceiling in three parallel rows—one red tube and two blue—and the effect of this diffused brilliance is enhanced by the green and white chequered flooring, the tiled walls and counter fronts, and other modern fittings. Light signalling by pre-arranged combinations of four different colours is used throughout the store for attracting the attention of managers or other persons.

Soil Science at Adelaide

The Winter School in Soil Science held during August 14–23 at the Waite Agricultural Research Institute, Adelaide, was a signal success. It was sponsored by the Council for Scientific and Industrial Research and the University of Adelaide and met under the chairmanship of Prof. J. A. Prescott. Sixty members attended, all directly engaged in work on soils, and representative of universities, State departments of agriculture and of forestry, water supply commissions, Government chemical laboratories and other interests. Papers were presented on classification, physical composition, colour, water relations, acidity and lime requirement of soils; methods of soil surveying and utilization of soil maps and data; spectrochemical and polarographic methods of analysis; methods for determination of soil carbon, soil reaction and soluble salts; the erosion problem in pastoral areas; and other topics. Numerous demonstrations were arranged. As a result of the School, soil investigators throughout the Commonwealth will in future be working in more intimate association and along more uniform lines.

Rare Medical Books

On the occasion of the seventieth birthday earlier this year of the late Prof. Harvey Cushing, Schuman's of New York brought out, under the title of "Seventy Noteworthy Medical Rarities", an illustrated and annotated catalogue to which are prefixed a portrait of Dr. Cushing, taken about forty years ago, and an appreciation of the eminent surgeon and bibliophile by Dr. Lawrence Reynolds. Among the notable works listed in the catalogue may be mentioned a thirteenth century medical manuscript on vellum containing some of the works of Constantinus Africanus, Giles of Corbeil and others, the work of Bartholomaeus Anglicus entitled "De Proprietatibus Rerum" (1535), Ambroise Paré's "Dix Livres de la Chirurgie" (1564), Gasparo Aselli's book on the lacteals (1627), Robert Boyle's "Sceptical Chymist" (1661) and modern works by Oliver Wendell Holmes, Sir William Osler and S. Weir Mitchell.

The Science Library

The Science Library, Science Museum, South Kensington, is remaining open. Books and periodicals are available for consultation in the reading room and for external loan to institutions engaged on research work. A relatively small number of the older books and periodicals have been removed and are not at present available. Although difficulty is anticipated, every endeavour will be made to maintain the collection of important current foreign scientific and technical literature up to the pre-war degree of completeness. The bibliographical and information service of the Library will be maintained so far as the reduced resources permit.

Royal Astronomical Society

The meetings of the Royal Astronomical Society will continue to be held at Burlington House, London, but at an earlier hour. The *Monthly Notices* and also *Occasional Notes* will be published so far as possible, but the former will not necessarily appear each month. The library will be closed except on meeting days, as the assistant secretary and office have been transferred to Oxford. The Christmas lecture, soirées, etc., have been postponed indefinitely. Prof. H. H. Plaskett, the senior secretary, is serving in the Royal Artillery, and Prof. W. M. H. Greaves has been appointed acting secretary for the present.

British Astronomical Association

The annual general meeting of the British Astronomical Association will be held as usual on October 25, in accordance with the articles of the Association, and no arrangement has been made at present to alter procedure in the matter of ordinary meetings. The president, two secretaries and treasurer have been empowered to conduct the business of the Association if war-time emergency should cause a discontinuance of the meetings. If this contingency arises, the *Journal* will still be published monthly, and it is hoped that papers will be contributed as usual by members. The library will be open only on the second and fourth Wednesdays of each month, but the librarian has power to refrain from opening in case of emergency.

Institute of Physics

The offices of the Institute of Physics have been transferred to the University of Reading, where accommodation had been reserved for them, by the kindness of the Council of the University. It is hoped to carry on so far as possible the normal work of the Institute, with such further activities as may be necessitated by emergency conditions. The Institute is in touch with Government departments and other employers, and has been collecting and collating such information as is available regarding the employment of physicists during war conditions. A considerable number of inquiries for advice on this and other emergency matters have received attention. It has been decided, unless unpredictable circumstances intervene, to continue the publication and distribution of the *Journal of Scientific Instruments* on the same terms as in the past, though it may be necessary to reduce to some extent the number of pages in each issue.

Announcements

Dr. Ian Galloway has been appointed scientific superintendent of research at the Pirbright Research Station of the Foot-and-Mouth Disease Research Committee.

Dr. S. C. Harland has been appointed director of the Institute of Cotton Technology of the National Agricultural Society of Peru.

Sir Frederick Menzies has resigned his position as medical officer of health and school medical officer of the London County Council, and has been succeeded by Dr. William Allen Daley.

In the hope of giving assistance to students in London who have been unable to follow their university colleges into the provinces in the present emergency, the managers of the Royal Institution have arranged for additional short courses of lectures to be given dealing in an introductory manner with certain subjects of modern physics and chemistry. Applications should be made to the Royal Institution, 21 Albemarle Street, London, W.1.

It is hoped to arrange day and/or evening courses in electrical methods of chemical analysis, microchemical analysis, spectroscopy and bacteriology at the Sir John Cass Technical Institute. Those wishing to take classes in these subjects should write, stating possible days and hours of attendance, to Dr. E. de Barry Barnett, Sir John Cass Technical Institute, Jewry Street, London, E.C.3.

The governing body of the British Medical Postgraduate School has decided to carry on postgraduate instruction for the present.

Owing to the war, the International League against Rheumatism will no longer be able to carry out its activities, and its bureau at Keizergracht 489, Amsterdam, will be closed.

Eighteen cases of smallpox were notified in England in 1938, of which nine were variola major and nine variola minor, and there were three deaths. These are the first deaths from smallpox which have occurred in England since 1934.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 713.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Kinematical Relativity and the Geological Time-Scale

IN a recent paper, a detailed analytical theory of time-keeping has been developed on an axiomatic basis[1]. Starting from the existence of a temporal sequence for events at any given observer and the existence of a 'substratum of equivalent observers', it has been found that amongst all possible graduations of the clocks of a substratum two families stand out with special properties, namely, the family τ, according to which the substratum is described by each of its members as static, and the family t, according to which it is described as uniformally expanding from a point origin. By deriving the equation of motion of a free particle, it has been found that if we identify the smoothed-out universe of extra-galactic nebulæ with a substratum, then the uniform time of dynamics is to be identified with τ-time[2], which gives an infinite 'age' to the universe, whereas the uniform time of optics and atomic vibrators is to be identified with a t-time[3], which gives 2×10^9 years as the 'age of the universe'.

It is well known that this 'age of the universe', as derived from Hubble's law, is of the same order as the 'age' assigned to the oldest rocks on the earth's surface by analysis of their uranium-lead ratio. This result, by itself, cannot be taken as conclusive evidence that this is the earth's 'age' because, as Holmes remarks[4], "Hutton's oft-quoted dictum that he could find 'no vestige of a beginning' remains true of geology to this day. Geological time dates from the deposition of the oldest known sediments, and whatever their age may be that of the earth must be still greater". However, strong corroborative evidence for the significance of this figure comes from recent investigations of the helium ratio of iron meteorites, about 70 per cent of which are now believed to reach our planet from outside the solar system[5]. These again lead to a greatest 'age' of the order 2×10^9 years.

These investigations of rocks and meteorites are based on the Rutherford-Soddy law of radioactive decay, which states that if N is the number of atoms of a particular radioactive element present in a specimen at a given epoch, and if δN is the number of these atoms which disintegrate in the subsequent interval δt, then

$$-\delta N = \lambda N \delta t,$$

where λ has been found to be independent of temperature, pressure, etc. 'Ages' are then assigned by this law on the 'assumption' that λ is invariant for change of epoch. This, of course, is simply a *definition* of the particular uniform time of radioactive decay of a given element. Since different elements and methods lead to consistent results, we have good reason for believing that there is a unique uniform time of radioactive decay, and the agreement between the 'ages' assigned to the oldest rocks and meteorites with the 'age' assigned to the universe by Hubble's law makes it extremely plausible to identify this time with the uniform t-time of optics.

If, therefore, we regard the dates assigned to geological epochs as t-scale dates, it becomes of interest to compare them with the corresponding dates on the τ-scale, given by[6]

$$\tau = t_0 \log (t/t_0) + t_0,$$

where t_0 is the present t-epoch, since this is the scale which has been identified with the uniform time of dynamics. It is readily seen that if t_1 is any past t-epoch and τ_1 is the corresponding τ-epoch (the two scales agree on the value of the present epoch, t_0) then

$$t_0 - \tau_1 = t_0 \log (t_0/t_1).$$

We can, therefore, immediately compile the following table to illustrate the difference between the t- and τ-periods assigned to geological eras, all figures being in millions of years.

Geological period	t_1	$t_0 - t_1$	$t_0 - \tau_1$
Present	2,000	0	0
Base of Eocence Rocks	1,930	70	71
Base of Cretaceous Rocks	1,900	100	102
Base of Triassic Rocks	1,800	200	210
Base of Devonian rocks	1,700	300	325
Base of Ordovician rocks	1,600	400	445
Base of Cambrian rocks	1,500	500	575
Laurentian rocks	1,000	1,000	1,400
Oldest European rocks	500	1,500	2,800
Oldest rocks (Manitoba)	250	1,750	4,200
'Creation'	0	2,000	∞

We observe that the t- and τ-measures of the whole fossil period (Cambrian age to present) differ by about 15 per cent of the t-measure, which is not much greater than the probable error in assigning epochs by the present radioactive methods. Moreover, when we go back a thousand million years on the t-scale, that is half way back to 'creation', we find that the τ-measure of this period is not more than fourteen-hundred million years.

Fission of Uranium under Deuteron Bombardment

Since the phenomenon of neutron-induced fission of the uranium and thorium nuclei is now indisputably established, attention may be turned to the possible efficacy of other bombarding particles in this respect. An outline is here presented of evidence suggesting that high-energy deuterons are, in fact, capable of producing fission in uranium.

The following experimental arrangement has been used. One inside surface of a copper box is covered with a 20 mgm./cm.^{2} layer of uranium metal, and is bombarded by deuterons passing through an aperture in the opposite side of the box. An inside pocket on one of the other walls contains metal foils for the purpose of collecting particles projected from the target through an aperture in the pocket. A thickness of 2 mm. S.P. aluminium is always present to protect the collecting foil from the low-energy products due to mechanical disintegration of the target. Bombardments of about 1 μamp. for ten minutes are convenient, and are found to produce on the collector activities of intensity suitable for measuring with a Geiger counter.

It is necessary to estimate what part of the activity on the collector is due to general neutron radiation and to deuterons scattered from the target. In the pocket are placed three foils of 3·3 mgm./cm.^{2} aluminium, F, D and N in order of proximity to the target, and a single thickness of half-millimetre copper sheet between the foils D and N. Five minutes after a 4 μamp./min. bombardment with 9 Mv. deuterons, it is found that the neutron effect of the irradiation has produced in N a small activity of 40 counts per minute; the neutron effect is eliminated from D and F simply by subtraction of this N effect. D's activity measures the scattered-deuteron effect and is initially about 100 counts per minute, decaying with a half-life of 2·3 min. to reach a negligibly small value after 20 min. F's activity, however, is about 1,500 counts per min., and is much longer-lived, although with a target entirely of lead, F as well as D shows only a D effect.

The decay curve for F's activity has been followed for about 7 hours and has been compared with that calculated from Frisch's formula[1] for the decay of multiplex activity. The measure of agreement is so substantial as to preclude the possibility of a merely accidental coincidence.

A stack of six 0·66 mgm./cm.^{2} aluminium foils has been placed in the pocket and after the lapse of 30 minutes (when the D effect has decayed) the activities are found to decrease regularly through the stack, reaching inappreciably small values in the fifth and sixth foils. Regarding another aspect, the fact that replacement of aluminium as the collector material by silver causes no significant difference in the decay curve, suggests that the activity has been implanted rather than induced. The evidence thus indicates that radioactive nuclei are projected from the uranium target with a range of the order of 2 cm.; this occurrence is evidently to be ascribed to a fission of the uranium nucleus.

It is important to assess the magnitude of the fission effect caused by background neutron radiation, and for this purpose there has been enclosed in the pocket itself a layer of uranium, separated from F by 2 mm. S.P. of aluminium, and from the target by the copper sheet, this arrangement necessarily reproducing fairly closely that activity in F which is due to neutron-induced fission. The intensity in this case is less than one twentieth of that observed in the positive experiment.

Approximate measurements have been made on the excitation function for deuteron-induced fission, using aluminium absorbers to modify the energy of the beam and a suitable disposition of diaphragms to protect the collector against deuterons scattered from the absorbers. The threshold for the process appears to lie at about 8 Mv., and the cross-section increases rapidly in the range 8–9 Mv.

The conclusions drawn from these preliminary experiments would receive unequivocal confirmation from a chemical identification of the fragment nuclei or a detection of their large ionization impulses in an ionization chamber. It might also prove profitable to examine the effects given by others of the heaviest elements (especially thorium).

Dr. R. S. Krishnan and other colleagues of the Cavendish cyclotron group have rendered me indispensable assistance, and I am indebted also to Prof. J. D. Cockcroft for pertinent suggestions.

Absorption of Polymolecular Films in the Infra-Red

The use of infra-red absorption spectra as a means of investigating molecular structure has still to be extended to surface films. Until very recently, the possibilities of this extension seemed remote, since a monomolecular layer does not contain enough molecules per square centimetre to produce measurable absorption. Thus it is found experimentally that approximately 10^{19} molecules are required to produce appreciable absorption in a beam of 1 sq. cm. cross-section, whereas the number of molecules per square centimetre in a monomolecular layer is about 5×10^{14}. With the production of polymolecular films close to 1,000 molecules thick, the possibility of detecting absorption still seemed slight, but technically feasible, if a method employing several reflections through such a film were employed.

As a matter of interest, it was decided to try whether any absorption could be detected using a single reflection through a film of methyl stearate 700 molecules thick, deposited on a chromium-plated strip of metal. We were surprised to find that the well-known absorption at 3·3 μ due to CH groups was easily detectable, showing about 30 per cent absorption, while other weaker bands were noticeable between 6 μ and 10 μ. Next, a film only 200 molecules thick was tried. This still gave the 3·3 μ band with appreciable intensity. These results mean that absorption spectra were being obtained from approximately 10^{17} molecules, instead of the customary 10^{19}. In other words, the absorption coefficient of a molecule in the infra-red seems to be considerably increased when it is in a surface film.

The possible causes of this will not be discussed here. The purpose of this note is merely to record this fact, which opens up a new and potentially interesting field of research in infra-red spectroscopy and its application to problems of molecular structure. In particular, this may prove to be a very suitable method of studying protein molecules.

We wish to express our thanks to Dr. Stenhagen, who prepared the films.

Analysis of Varying Sound

The only reasonable method of frequency analysis applicable to the case of varying sound as yet published is that of Germansky[1] and Brown[2], using diffraction of light by varying-density sound-film. But the technical difficulties owing to low dispersion seem to prevent further development in practical applications of that method. I have recently used a very simple photographic method of frequency analysis which can be designed so as to satisfy all the requirements met with in the analysis of any sounds or other vibrations.

The essential part of this method is a photographic plate (analysing plate), illustrated in Fig. 1, in which the transmitted light intensity varies as $A + B\sin\frac{2\pi}{d}x$, $(0 < B < A)$, along the x direction in the figure, and the wave-length d varies continuously in the y direction. The incident light intensity is varied according to the sound to be analysed, and a photographic film is moved at constant velocity along the x direction at the back of the analysing plate.

Let the incident light intensity be expressed as $P + Qf(t)$, $(0 < Q|f(t)| < P)$, and the velocity of the film be V; then a point on the moving film receives an amount of light which can be expressed as

$$\int_{-Nd}^{Nd} \left[P + Qf\left(\frac{x-\xi}{V}\right)\right]\left[A + B\sin\frac{2\pi}{d}x\right]dx,$$

where ξ is the co-ordinate of the point at $t = 0$, and $2N$ is the number of waves in the analysing plate. If N is sufficiently large, the above integral reduces to a constant term added to the expression

$$QB\int_{-Nd}^{Nd} f\left(\frac{x-\xi}{V}\right)\sin\frac{2\pi}{d}x\,dx = QB\int_{t_1}^{t_2} f(t)\sin\frac{2\pi}{d}(Vt+\xi)\,dt,$$

which is practically the Fourier component of $f(t)$. On a uniform background, sharp lines, the blackness of which varies sinusoidally, are obtained stroboscopically, one corresponding to each component.

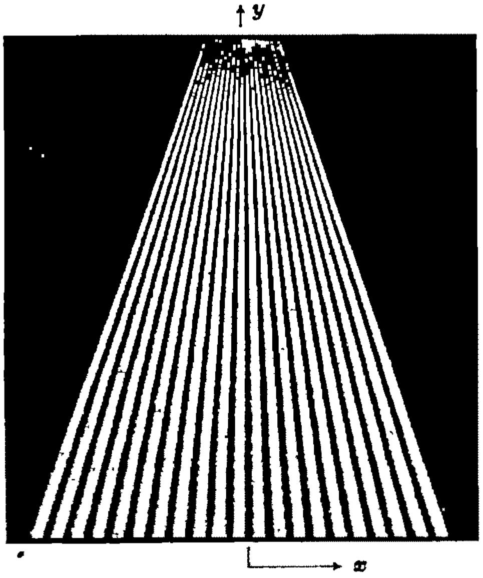

Fig. 1
Analysing Plate

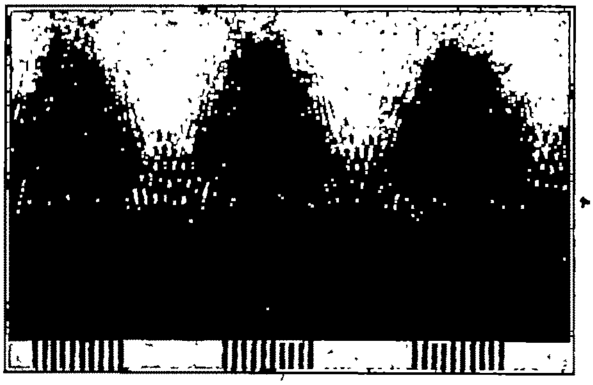

Fig. 2

If the number N is not very large, these lines are broadened to bands, and this broadness limits the resolving power. In the case of varying sound, the variation of the spectrum can be followed by making N sufficiently small, so that the resolving power of frequency and that of time counteract each other. But this is not a defect in the method. The lack of resolving power in frequency is complementary to precise knowledge of time variation, and vice versa.

A simple example is given in Fig. 2, which shows the analysis obtained for the 'square waves' (10 pulses followed by an intermission of 10 periods) shown at the bottom of the figure, n_0 being the fundamental frequency. A preliminary test of the application of this method to the analysis of speech was also undertaken. The variation of word pitch and the crossing of different successive overtones over the formant region of the vowels were clearly observed.

The analysing plate can be modified in various ways for different purposes, Fig. 1 being merely an example. Further, the sinusoidal transmission character of the analysing plate may be generalized to any orthogonal sets of functions, and thus a method is obtained of expanding given functions in series or integrals of some suitable orthogonal functions.

Another application of the analysing plate is found in the artificial composition of sound. By throwing on the plate suitably formed moving rays of light, and receiving the transmitted light on a photo-cell, any desired sound can be produced.

The construction of this analysing apparatus and investigations of some of its applications are now in progress in Prof. Takeo Hori's laboratory. I wish to express my gratitude to Prof. Hori, and also to the Hattori Hokokai for financial support.

Atomic Parameters of γ-Silver - Cadmium

Readjusting atomic parameters of γ-brass, we have calculated three successive sets of atomic parameters for γ-silver - cadmium. These sets we tested by comparing the intensities calculated with them with the observed intensities of the reflections of γ-silver - cadmium. For our thrice readjusted atomic parameters, namely, $a = 0{\cdot}105$, $b = 0{\cdot}175$, $c = 0{\cdot}358$, $d = 0{\cdot}310$, and $e = 0{\cdot}038$, the agreement between the observed and the calculated intensities was sufficiently good to afford confirmation of the correctness of these values. Interatomic distances calculated from these adopted atomic parameters suggests a regular distribution of the silver and the cadmium atoms, silver atoms occupying positions of B atoms and C atoms, cadmium atoms those of A atoms and D atoms.

Our calculations were based on powder photographs and the data of reflections made available to us by Prof. A. Westgren of the University of Stockholm. A detailed account of them will be published in the *Acta et Commentationes Universitatis Tartuensis*.

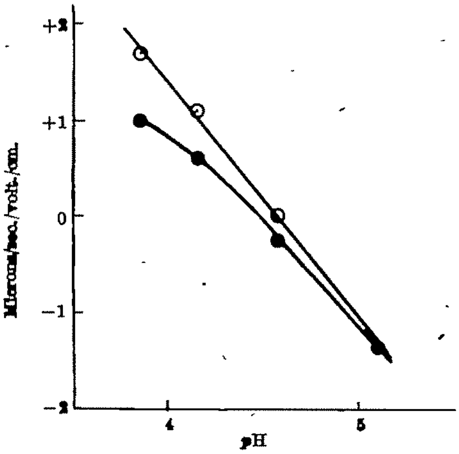
Cataphoretic Measurements on Solutions of Visual Purple and Indicator Yellow

LIGHT transforms visual purple, the substance responsible for scotopic vision, into a yellow compound, the colour of which depends on pH ('indicator yellow'[1]). Visual purple behaves as a coloured protein, that is, it is a 'chromoprotein'. Experiments have been carried out to see if a shift of the isoelectric point occurs on bleaching.

The visual purple was obtained from Hungarian frogs by means of extraction with digitonin, and the solution dialysed for long enough to remove the bulk of the salts, but not to precipitate the protein. Measurements were made with a micro-cataphoretic cell which will be described elsewhere. Quartz particles of the size 2–5 μ were suspended in the solution and $N/100$ acetate buffer added. The particles adsorb the chromoprotein and their movement is governed by the ionization of the latter[2]. The measurements on visual purple were carried out in ruby light to prevent bleaching. After each determination, white light was switched on without removing the cell, so transforming the visual purple into indicator yellow. During the bleaching the cataphoretic velocity of the particles increased in solutions more acid than about pH 4·5, and decreased in solutions more alkaline than pH 4·5. After a few minutes a steady velocity was reached, which was independent of whether observation was made with ruby or white light.



THE VARIATION OF THE CATAPHORETIC VELOCITIES IN SOLUTIONS OF VISUAL PURPLE AND INDICATOR YELLOW WITH pH VALUE

The cataphoretic velocities before and after bleaching for one preparation are plotted against pH in the accompanying graph. It appears that the isoelectric point of the particles in the visual purple solution is 4·47, and in the indicator yellow solution 4·57 pH units. Other preparations gave the same type of curves and the same shift on bleaching, but sometimes the positions of the isoelectric points were slightly different (±0·1). The isoelectric points are, therefore, in a comparatively strongly acid range. This explains the observation that solutions of visual purple become acid on prolonged dialysis against distilled water[3].

No other case appears to be recorded in literature where moderate illumination produces a change in the isoelectric point of a protein or chromoprotein. The bleaching process of visual purple is apparently associated with an increase in the number of alkaline groups, such as NH_2, available for ionization.

Our thanks are due to the Rockefeller Foundation for financial help.

A Mechanism for the Concentrating of Potassium by Cells, with Experimental Verification for Muscle

THE membrane considered is one of special type, with cation and anion pores, permeable to potassium but not to larger sodium ions, and permeable at the same time to small anions of the type of chloride, bicarbonate, phosphate, etc., but not to larger anions such as hexose esters, phosphocreatine, etc. The concentrations inside (or within the cell) and outside the membrane are represented as follows: B/V and b, impermeable cations; k_1 and k, potassium; d_1 and d, permeable anions; A/V, impermeable non-colloidal anions; C/V, colloidal anions inside; x, external impermeable non-electrolyte such as glucose.

The permeable anions, which will be almost entirely chloride and bicarbonate, are considered as monovalent, and the valencies of B, A and C are written as m, n and p. V is the volume of the solvent inside, which is considered to be initially one litre. The quantities A, B and C are regarded as independent of V. The total external concentration is written as 'c'.

From the requirements of the osmotic, electrical and Donnan equilibria we may deduce the following equations:

$$V^2(c^2-4kd)-2VKc+(K^2-K_1^2)=0 \quad . \quad (1)$$

$$2k_1 = c-(K-K_1)/V \quad . \quad . \quad . \quad . \quad (2)$$

$$kd = k_1d_1, \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$\text{where } K = B+A, \quad . \quad . \quad . \quad . \quad (4)$$

$$\text{and } K_1 = nA+pC-mB. \quad . \quad . \quad . \quad (5)$$

Reckoning the value of $(K-K_1)$ from the available data, it is found to be sufficiently small to be neglected in approximate calculations, so that we may write for (1) and (2) :

$$V = \frac{2Kc}{c^2 - 4kd} \quad . \quad . \quad . \quad . \quad . \quad (6)$$

$$\text{and} \quad k_1 = c/2, \quad . \quad . \quad . \quad . \quad . \quad (7)$$

From equations 6 and 7 it appears that as potassium is substituted for sodium in the external solution, the potassium concentration in the cell will remain unchanged, but potassium will enter and the cell volume increase. As the external concentration is increased, the potassium concentration inside will increase ; but if the external potassium is also raised, the volume will stand higher than otherwise and potassium will have entered the cell.

When excised muscle is immersed in Ringer or Barkan fluid, potassium is lost until the external potassium is 29 milliequiv./litre. The raised equilibrium value appears associated with widening of the cation and anion pores, and it is from this raised value we shall consider the effect of potassium changes. The interspace fluid is taken as 9 ml./100 gm. tissue (from magnesium and inulin methods), though small differences with total volume changes will not materially affect the calculations.

The following table illustrates the kind of results obtained ; each figure being the mean of four or five experiments. Concentrations are expressed as milliequiv./litre of external fluid or 'fibre' water (which latter is normally 71 ml./100 gm. muscle).

Potassium conc. in ext. fluid	Total conc. of ext. fluid	Potassium conc. of 'fibre' water Exper.	Theor.	Potassium entry. Milliequiv./litre of 'fibre' water
2·5	240 (plasma)	119	120	
33·5	248	115	124	12·5
103	256	121	128	83·8
103	384	196	192	33·2
103	534	263	267	8·8

For equation 3 we have the following data, taking chloride as an example of the permeable anion.

External conc.		Inside conc		Products	
K	Cl	K	Cl	K × Cl	K × Cl
29	106	119	26·6	3074	3165
80·4	132	145	73·0	10613	10585

Original entrance of potassium and relation of potassium interchanges to carbohydrate metabolism. Here we shall consider briefly an apparently easy and effective means of increasing the potassium in cells without change in external potassium or in total concentration outside. If, in the above scheme, impermeable anions are formed from permeable, V the volume of the cell will increase from equation 6, and potassium and more diffusible anion will enter the cell in accordance with equations 3, 2 or 7. No intermediation of hydrogen ion with its excessively low gradients will be necessary. A permeable anion that could play this part pre-eminently is phosphate, and when we examine the nature of the impermeable non-colloidal anions within the fibre we find that they are mostly if not quite formed of phosphorylated compounds important for the carbohydrate cycle. If such compounds decrease in concentration during rapid carbohydrate oxidation, potassium should leave the cell, and when reformed the reverse should occur. A relation between carbohydrate metabolism and potassium interchanges has, in fact, been already noted (for example, by Verzar) and is here rationally interpreted.

With the above membrane the potential changes with varying external solutions can also be readily understood, previous explanations assuming chloride impermeability being demonstrably incorrect.

The above research was supported by a grant from the Irish Medical Research Council.

Action Potentials Recorded from Inside a Nerve Fibre

Nervous messages are invariably associated with an electrical change known as the action potential. This potential is generally believed to arise at a membrane which is situated between the axoplasm and the external medium. If this theory is correct, it should be possible to record the action potential between an electrode inside a nerve fibre and the conducting fluid outside it. Most nerve fibres are too small for this to be tested directly, but we have recently succeeded in inserting micro-electrodes into the giant axons of squids (*Loligo forbesi*)[1].

The following method was used. A 500 μ axon was partially dissected from the first stellar nerve and cut half through with sharp scissors. A fine cannula was pushed through the cut and tied into the axon with a thread of silk. The cannula was mounted with the axon hanging from it in sea water. The upper part of the axon was illuminated from behind and could be observed from the front and side by means of a system of mirrors and a microscope ; the lower part was insulated by oil and could be stimulated electrically. Action potentials were recorded by connecting one amplifier lead to the sea water outside the axon and the other to a micro-electrode which

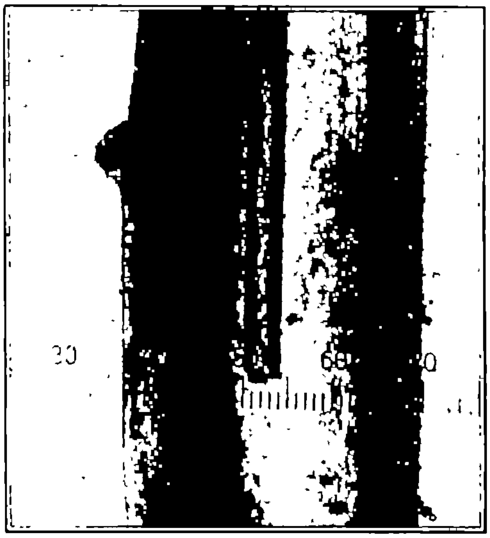

Fig. 1.

Photomicrograph of electrode inside giant axon. 1 scale division = 33 μ.

was lowered through the cannula into the intact nerve beneath it. The micro-electrode consisted of a glass tube about 100 μ in diameter and 10–20 mm. in length; the end of the tube was filled with sea water, and electrical contact with this was made by a 20 μ silver wire which was coated with silver chloride at the tip. Fig. 1 is a photograph of an electrode inside the living axon. The giant axon shows as a clear space and is surrounded by the small fibres and connective tissue which make up the rest of the nerve trunk. The silver wire can be seen inside the electrode and about 1 mm. from its tip. A small action potential was recorded from the upper end of the axon and this gradually increased as the electrode was lowered, until it reached a constant amplitude of 80–95 mv. at a distance of about 10 mm. from the cannula. In this region the axon appeared to be in a completely normal condition, for it survived and transmitted impulses for several hours. Experiments with external electrodes showed that the action potential was conducted for at least a centimetre past the tip of the micro-electrode.

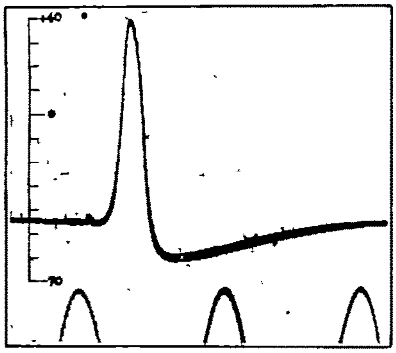

Fig. 2.

Action potential recorded between inside and outside of axon. Time marker, 500 cycles/sec. The vertical scale indicates the potential of the internal electrode in millivolts, the sea water outside being taken at zero potential.

These results are important for two reasons. In the first place they prove that the action potential arises at the surface, and in the second, they give the absolute magnitude of the action potential as about 90 mv. at 20° C. Previous measurements have always been made with external electrodes and give values which are reduced by the short-circuiting effect of the fluid outside the nerve fibre.

The potential difference recorded between the interior and exterior of the resting fibre is about 50 mv. The potential difference across the membrane may be greater than this, because there may be a junction potential between the axoplasm and the sea water in the tip of the electrode. This potential cannot be estimated, because the anions inside the nerve fibre have not been identified.

We wish to express our indebtedness to Mr. J. Z. Young, whose discovery of the giant axon in *Loligo* made this work possible.

Legume Nodule Metabolism and Nitrogen Fixation

The extent of nitrogen fixation in legume nodules is governed primarily by the carbohydrate supply[1,2]. Quantitative information concerning the carbohydrate and nitrogen metabolism of nodules is, however, somewhat limited. Investigations of this subject, conducted during the past four years, are here reported upon briefly.

The experimental procedure involved the use of standard manometric techniques supplemented by chemical analyses. Nodules from twelve species of legumes were compared with normal root tissues of these legumes and of twelve species of non-legumes. These tissues were detached from young field-grown plants, washed, and used as quickly as feasible in Warburg respiration experiments, or otherwise as desired. The outstanding results of these studies are given below.

Variations in behaviour between samples of nodules of different species were not much greater than between samples of the same species, hence the selection of a species for an experiment was relatively unimportant. The same generalization applies also to root tissues.

The inner tissues of most nodules kept in air were under partially anaerobic conditions; this was likewise true for large nodules even in oxygen. This conclusion is based upon the relative rates of respiration and respiratory quotients of nodules and roots in different partial pressures of oxygen. In air, the average Q_{O_2} of whole legume nodules and small roots of legumes and non-legumes was about 2·2; the values for nodules immediately after crushing usually varied between 3 and 7. The use of pure oxygen increased the average Q_{O_2} of whole nodules to about 5·3, but changed that of small roots only slightly. Small root tissues are evidently well aerated, even in air. The *R. Q.* values of nodules increased with nodule size and with decrease in oxygen concentration. In air most nodules, even though small, showed *R. Q.* values considerably above 1·0, whereas in pure oxygen the values were usually near 1·0. Small legume and non-legume roots usually gave values appreciably below 1·0 even in air.

Small roots apparently contain less available carbohydrates than do nodules, since glucose additions increased the Q_{O_2} of the former about 40 per cent and of the latter 12 per cent. The smaller diameter of the roots, however, favoured sugar penetration, and this fact may account for a portion of the greater increase. Under anaerobic or partially anaerobic conditions both nodule and root tissues formed ethyl alcohol[3]; under aerobic conditions alcohol was oxidized completely to carbon dioxide and water.

The rates of respiration per unit of tissue nitrogen of legume and non-legume roots was 3–4 times as great as for nodules in air, and twice as great as for nodules in oxygen. This indicates that a considerable portion of the nitrogen in nodules is either in storage, translocatory or other biologically inactive compounds.

Repeated attempts to obtain nitrogen fixation by detached nodules of different species and ages and maintained under various conditions were, with one possible exception, unsuccessful. Nitrogen analyses were made either by the Kjeldahl method or by gas analysis.

These experimental results are in harmony with the generally accepted idea that the bacteria in nodules are mostly in a dormant condition. Under ordinary atmospheric conditions the Q_{O_2} of nodule tissue was not greatly different from that of young root tissues, and the average respiration rate of the bacteria corresponded to or was even lower than that of resting rhizobia (Q_{O_2} usually about 6–8) in culture. Considering, furthermore, that nodules usually represent only 1–5 per cent of the total dry weight of the plant, it is obvious that the bacteria in the nodules oxidize only a small portion (see earlier discussion[1]) of the carbohydrate synthesized by the host plant. The bulk of the carbohydrate supply that largely determines the magnitude of nitrogen fixation is actually used by the host in its growth processes.

A detailed account of these investigations will be published shortly in a series of papers.

Correlation between Seed Weight and 'Adult' Weight in Tomatoes

In a recent contribution to the study of heterosis, Luckwill[1] adduces evidence that in different crosses of tomatoes hybrid vigour may appear at different stages in the life-cycle. He states that in certain crosses "there was found to be very little correspondence between the presence of heterosis in the seed and in the mature hybrid". A possible reason for this, as Luckwill mentions, is that seed size is influenced by other than genetic causes, but there is another explanation which has been overlooked, and which is important in all such studies of plant growth.

In Luckwill's experiments seeds of known weight were planted in pots, and were afterwards transplanted "with the greatest possible care" into garden plots. Luckwill assumes that the disturbance in growth due to transplanting does not interfere with any correlation between seed weight and adult weight, and that if seed weight is important in determining size, larger seeds should give rise to larger plants, notwithstanding this treatment. The following data show that this assumption is incorrect.

Covariance of seed weight and adult weight for ten strains of tomatoes, between means of strains.

Treatment	Degrees of freedom	Sums of products	r
Transplanted	9	18·8193	0·503, not significant
Control	9	28·7683	0·949, significant

Weighed seed of ten strains of tomatoes (five inbred lines and five F_1 crosses) were planted in uniform conditions in a greenhouse. After an interval of 31 days half the seedlings were transplanted with great care into ten-inch pots. The other half remained in the ten-inch pots in which they had germinated. The transplanted and control seedlings were arranged in blocks in a greenhouse, to facilitate statistical analysis. On the 78th day after germination, as the first flowering truss appeared, the plants were harvested, dried in a stream of air at 95°, and weighed. The accompanying table shows the result of an analysis of covariance between seed weight and adult weight for the transplanted and control plants.

It is clear that there is a highly significant correlation between seed weight and dry weight at the onset of flowering, and that this correlation is destroyed if the plants are transplanted between sowing and harvesting, however carefully the transplanting is carried out. It seems obvious that Luckwill's method of comparing the significance of differences of means of seed weight on one hand, and of means of fresh weight 145 days after planting, and after transplanting, on the other hand, can give no reliable information as to the relation between seed size (whether in hybrids or inbred lines) and adult size.

A full account of these experiments will shortly be published.

Loaded Dice

Dice have been used as a game of chance from time immemorial and have in all ages been associated with gambling for high stakes. Loaded dice or dice adjusted to increase the probability of a particular face or one of a group of faces turning up have been used by swindlers from very early times, and such methods of destroying symmetry as unsymmetrical weighting and slight alteration of form are well known. Even in the case of normal dice, the method of numbering the sides may cause a slight departure from perfect symmetry, and there may be justification for the alleged belief of professional gamblers that there is a slight tendency for the higher numbers 4, 5 and 6 to turn up more often than 1, 2 and 3.

Dice are numbered in such a way that the sum of the numbers on opposite sides is always 7. There are two possible arrangements which are mirror images of each other, but I do not know whether both are used. The numbers 1, 2 and 3 are grouped around one corner of the cube and the opposite numbers 6, 5 and 4 around the diametrically opposite corner. It follows that if conical or hemispherical holes are used for numbers, since more material is removed the higher the number, the centre of gravity will be displaced towards the corner adjoining the three low numbers, and there should in consequence be a slight bias in favour of the higher numbers turning up, the magnitude of the bias being increased with the size of the holes. There should also be a bias, though very much smaller, in favour of even numbers against odd numbers.

Attempts to detect such a bias by a very large number of throws have, I believe, been recorded but I am unable to trace such records. Experimental detection of a bias would not show, however, that the bias was due to displacement of the centre of gravity, since another and very important factor is involved, namely, lack of uniformity in the frictional resistance of the surfaces of the die.

In professional gambling, dice are thrown along a plane surface of correct texture such as a billiard table. A die near the end of its course with just sufficient momentum to overturn it, if arrested by the surface will, if its frictional resistance is low, slip forward without overturning, but if sufficiently retarded by friction will turn over on to the next face. The result of this can be more easily seen by considering dice marked, as they frequently are, black and white on opposite faces. If the black faces have low and the white higher frictional resistance, a die on its black face will slip forward and stay on that face when one with the same momentum but on its white face will turn on to one of the four adjoining faces, two of which are white and two black. Assuming that there is equal probability of a die being on any one of its six faces before frictional resistance is operative, friction can thus cause a large bias, of limiting probability 3 to 1 in favour of the die coming to rest with one of the faces of higher resistance on top.

In order to test this effect of frictional resistance, I marked plain, transparent coloured dice of the modern type with a small black dot on three adjoining faces and a small white dot on the three opposite faces, and treated the faces having black dots in various ways with the view of increasing resistance to slip without leaving visible signs of treatment. Excellent results were obtained with a specially prepared slow-drying colourless varnish, undetectable by appearance on the treated dice. When the varnish had hardened sufficiently, a slight difference of touch was detectable though not obvious. Numerous trials with treated dice thrown on a suitable surface, best on a billiard table, showed a most pronounced bias in favour of the treated sides with black dots turning up. The bias decreased as the varnish became harder, and was much smaller twenty-four hours later. The following throws made with a single die and grouped into hundreds are typical:

$$\frac{\text{black}}{\text{white}} = \frac{65}{35} + \frac{74}{26} + \frac{69}{31} + \frac{62}{38} + \frac{67}{33} + \frac{69}{31} + \frac{65}{35} + \frac{61}{39} = \frac{1\cdot 9}{1}$$

If two such dice are thrown, as in a common form of gambling, the probability of a pair of black against a pair of white is $1\cdot 9^2 = 3\cdot 6$ to 1.

With ordinary numbered dice with conical or hemispherical holes, it is possible that the frictional resistance may be increased or diminished with the number of holes according as the edges of the holes are sharp or rounded. Consequently, any observed bias cannot be attributed to displacement of centre of gravity unless the possibility of such bias being due to difference of frictional resistance has been eliminated.

Points from Foregoing Letters

The uniform time of radioactive decay is identified by G. J. Whitrow with the *t*-time of kinematical relativity, according to which the 'age of the universe' is of the order 2×10^9 years. Since this is not the uniform time of dynamics, according to which the 'age of the universe' is infinite, a comparison is made between the dates assigned to various geological epochs by radioactive methods and the corresponding dates in dynamical time. It is found that the two measures of the whole fossil period differ by an amount not much greater than the probable error in estimating its duration by the present methods.

D. H. T. Gant has bombarded uranium with high energy deuterons, and by studying the decay curve of the recoiling fragments he has obtained evidence suggesting that radioactive nuclei are projected from the uranium target with a range of the order of 2 cm., due to a fission of the uranium nucleus. The threshold for the fission process appears to lie at about 8 Mv. and the cross-section increases rapidly in the range 8–9 Mv.

G. B. B. M. Sutherland and W. T. Tutte report that appreciable absorption in the infra-red region of the spectrum between 3 μ and 10 μ is exhibited by polymolecular films only a few hundred molecules thick. This rather surprising result opens up a new field of research in the application of infra-red spectroscopy to the structure of surface films, and may be of importance in studying protein molecules.

K. Imahori describes a photographic method of frequency analysis which can be applied to sound.

From powder photographs by A. Westgren and H. Ålstrand, H. Perlitz and R. Aavakivi have calculated the atomic parameters of γ-silver - cadmium, finding by the method of successive approximations values which gave calculated intensities in good agreement with those observed experimentally.

E. E. Broda, C. F. Goodeve, R. J. Lythgoe and E. Victor find that the iso-electric point of visual purple is 4·47 *p*H units, and that it undergoes a shift by 0·1 *p*H units to the alkaline side on bleaching to indicator yellow. This is taken to suggest that bleaching results in an increase to the number of alkaline groups available for ionization.

A special type of cell membrane is dealt with by E. J. Conway and P. J. Boyle which is both anion- and cation-permeable up to certain size limits of the ions. Potassium, for example, is considered permeable and sodium impermeable. In contact with ionic media like blood plasma, such a membrane will result in a high internal potassium concentration being in equilibrium with a low value outside, and certain relationships can be deduced which are shown to apply to excised muscle. A relation with carbohydrate metabolism, and the manner of the original entrance of potassium into cells, are suggested.

A. L. Hodgkin and A. F. Huxley describe a method for inserting an electrode into a living nerve fibre. They have recorded action potentials of 90 mv. across the surface of the fibre.

Respiration studies made by F. E. Allison *et al.* show that the inner tissues of legume root nodules are usually partially anaerobic. Both nodule and root tissues may produce or oxidize ethyl alcohol, depending upon the oxygen supply. The rates of carbohydrate consumption under ordinary atmospheric conditions by nodule and young root tissues are usually about the same. Attempts to obtain nitrogen fixation by detached nodules were unsuccessful.

RESEARCH ITEMS

Blood Groups among Primitive Peoples

The British Association Research Committee on Blood Groups among Primitive Peoples, of which Prof. H. J. Fleure is chairman, reported at the Dundee meeting on its work during the year 1938–39. Results obtained by Dr. F. W. Vint in Nairobi, Kenya, in 1936, which it has not been possible to carry further, are recorded as follows: Individuals tested, 121 (Bantu, 73; half-Hamites, 5; Nilote, 33; mixed, 10); percentages: *O*, 42·1; *A*, 22·3; *B*, 30·6; *AB*, 5. In the Naga Hills, Assam, from observations in 1936–37, 407 tests were made in all. Of these 140 were of Angamis, Lhotas, Rengmas, and Semas, known historically to be of similar stock. They gave the percentages, Angamis, *O*, 35·4, *A*, 34·4; *B*, 25·0; *AB*, 5·2; while all four tribes together gave, *O*, 40; *A*, 33·6; *B*, 22·1; *AB*, 4·3. The percentages for the four tribes together do not differ appreciably from those for the Angami alone. Larger numbers are required to determine whether Semas, Lhotas and Rengmas show significant differences. Three other tribes were tested as follows: Konyaks (127): *O*, 45·7; *A*, 40·2; *B*, 10·2; *AB*, 3·9; Aos (57): *O*, 47·4; *A*, 22·8; *B*, 22·8; *AB*, 7·0; Thado Kuki (83): *O*, 19·3; *A*, 30·1; *B*, 32·5; *AB*, 18·1. These results accord with the view of Mr. J. P. Mills that the Konyaks are more primitive than the Angami-Rengma, that the Konyak and Aos have much more in common, and that the Thado Kuki are an entirely different race. The Konyak and Aos may be regarded as the most primitive in blood grouping. In Travancore 171 Kannikars, as well as Pulayas and other tribes, have been tested with results markedly different from the general population of Trivandrum. Anthropometric measurements and blood group tests have been carried out on 1,000 Egyptians of the Sharqiya Province, Upper Egypt; and 300 tests have been made in Co. Antrim, Northern Ireland, on individuals with a residential history in the district of three generations, to show whether local differences can arise in a small isolated population.

Alsea Ethnography

The Alsea, like other coast Oregon groups, have suffered both a decline of their numbers and a shattering of their culture under the impact of white civilization. At the time Philip Drucker collected data of their culture in 1933 (*Univ. California Pub. Amer. Ethnol. and Archæol.*, 35, 7; 1939) three persons only remained cognizant of their languages and customs; and from them these particulars were obtained. The Alsea territory comprised the two short river valleys of the Alsea and the Yaquina, and the ocean frontage between them. Adjoining to the north were the Salishan Tillamook; to the south the linguistically related Siuslaw and Lower Umpqua. They were never numerous. Their culture was definitely peripheral, possessing the broader outlines of Northwest Coast culture, but lacking the refinements of the focal civilization. They were off the main lines of communications, along which many complexes were diffused. They were a fisher folk, their choice of dwelling-sites, their seasonal migrations, and their technological interests reflecting the importance of this pursuit in their lives. Salmon ranked first of the several kinds of fish taken. Dried, it was the mainstay, which provided a winter of leisure to a people lacking a plentiful and easily preserved food source. Other fish and game only supplemented this diet. Of a full list of fishing devices, traps and harpoons were regarded as the most effective. Traps were used in conjunction with weirs. Dip-nets—conical sacks—were used. The salmon club was indispensable. Hunting was considered an adventurous way of supplementing the fish diet. Probably there were many who rarely hunted. Elk were hunted in the fall. Dogs were used to hold the elk at bay until the hunter came up. The paucity of hunting devices emphasizes the lack of interest in any pursuit other than fishing.

Behaviour of Tsetse Flies

Under the title of "Studies in the Physiology and Behaviour of *Glossina morsitans*", R. W. Jack, chief entomologist for Southern Rhodesia, gives a detailed account of observations made upon this species of tsetse fly (Mem. Depart. Agric., Southern Rhodesia, No. 1, 1–203; 1939). It embodies, in the main, the results of laboratory research, but certain field data are also included. It is evident, according to the author, that *Glossina morsitana* can thrive under a relatively wide range of conditions, given an adequate food supply. The only extremes of climatic conditions which might exclude *G. morsitans* from extensive tracts of country appear to be too low a mean temperature, which retards reproduction below the survival limit, and too high a maximum temperature especially if it is associated with an inferior cover of vegetation. Interference with the food supply is undoubtedly the best general method of eradicating this insect. It is possible, and economically feasible, in Southern Rhodesia to clear any kind of country of *G. morsitans*, but only at present at the expense of the wild game. With the object of finding alternative measures which can be used over wide areas, it is necessary to continue both laboratory and field research. Not enough is known to combat the fly in its habitat and at the same time to spare the game. A large proportion of the country in Southern Rhodesia infested with *G. morsitans* is relatively sterile, largely waterless, mostly unfit for Europeans and only capable of supporting a very scattered native population. Such areas constitute the major problem because, unless they can be cleared of the tsetse fly or shut off by an effective barrier, they will remain a constant danger to more valuable land where it may otherwise be possible to control the situation.

Replacement of Fangs in Rattlesnakes

The functional fangs of rattlesnakes are changed or replaced periodically, such replacement occurring whether the discarded fang has been damaged or is still intact. Laurence M. Klauber describes the method of replacement (*Occasional Papers*, No. 5, *San Diego Soc. Nat. Hist.*, Aug. 1939). There are two maxillary fang sockets on each side of the head, and these are used alternately as the site of the functional fang on that side. The next replacement fang always lies behind the vacant socket, in which it becomes anchored by the solidification of a bony pedestal when the time for replacement arrives. Replacement on the two sides of the head is not synchronous, but at the time of replacement there is a short period when the new fang and the one which will shortly drop out are both functional. Fang change is so frequent that only during the period of most rapid growth in the largest species can a difference in length be detected between a fang and its next replacement. The author also describes and illustrates the method by which the maxillary is rotated so that a fang can be translated from a resting position against the roof of the mouth to a striking or biting position perpendicular thereto. He notes that the fangs are particularly well adapted for biting rather than merely for striking.

Larval Trematodes in Molluscs

AN exhaustive memoir by Dr. Annie Porter on the larval Trematoda found in certain South African Mollusca, with special reference to schistosomiasis, was published in 1938 by the South African Institute for Medical Research (No. 42, 8, Johannesburg). The memoir is zoological, and describes very fully the life-history of *Schistosoma hæmatobium* and *S. mansoni*, their intermediate molluscan hosts, experiments on transmission, and methods of control—an invaluable survey for the medical man and the parasitologist. In South Africa the vectors of *S. hæmatobium* are the snails *Physopsis africana* and *P. globosa*, while *S. mansoni* is carried by *Planorbis* (? *Biomphalaria*) *pfeifferi*, *Physopsis africana* and *Bulinus tropicus* (Cf. Mozley's paper on the fresh-water molluscs conveying schistosomiasis in Tanganyika, NATURE, 143, 951; 1939). Dr. Porter was able to obtain all stages of the parasites from egg to adult, and successfully carried out artificial infection of the snails by miracidia, and of rats and puppies by cercariæ obtained from the snails. She also investigated the penetration of the skin by the cercariæ in native children bathing in infested pools. She concluded that persistent education, treatment of sufferers and mollusc control are the most effective methods of reducing the incidence of both urinary and intestinal forms of this terrible disease. Shorter accounts of other species of Schistosoma follow. The greater part of the book is taken up with descriptions of cercariæ, mostly of unknown parentage, collected by the author from South African snails and studied alive. The eighty-one plates drawn from living material are to be commended for their excellence.

Caridea of the John Murray Expedition

SEVEN new species of Caridea have been described by W. T. Calman and eighteen recorded for the first time from the area traversed by the *Mabahiss* (British Museum (Natural History). The John Murray Expedition 1933–34. Scientific Reports, 6, No. 4. Crustacea : Caridea. 1939). Most of the sixty-seven species identified were from deep water and include some particularly interesting forms. One new species of Plesionika, *P. minor*, has epipods on the first two pairs of legs only, thus being intermediate between Plesionika and Parapandalus. *Parapandalus filipes* n.sp. is peculiar in having the fourth and fifth legs very long and of "thread-like tenuity", the propodus being excessively attenuated and the dactylus microscopic. Two new Pontoniids, both found in association with sponges and referred to the genus Periclimenes and to the sub-genus Periclimenœus and Ancylocaris respectively, are very much alike, and the second resembles *Periclimenes* (*Periclimenœus*) *robustus* of Borradaile in its massive claws, the armature of the fingers and the short thick claws of the walking legs. It is possible that Borradaile's species may also be associated with sponges. *Periclimenes* (*Ancylocaris*) *crassipes* is the only one of these three with simple claws on the walking legs, but otherwise resembles the others very closely : this supports the suggestion of Kemp (1923) that Periclimenœus may not deserve to be even a sub-genus. None of the three has a hepatic spine, which seems to be a further reason for placing them together.

Vegetation of a South Westmorland Fell

THE district described by Alwyn Bennett (N. W. Nat. Union Year Book 1936–37, 19–48) lies between Burton-in-Kendal and Hutton Roof, and its chief ecological interest lies in the close proximity of limestone and acid gravel drift. The glacial drifts, formerly covered by oakwoods, are now, as a result of deafforestation and subsequent grazing, largely covered with bracken, which is actively spreading on land gone out of cultivation. Changes in the ground flora consequent upon the eradication of bracken by cutting and burning are outlined. The limestone area shows stages in development of closed communities from bare scree slopes to grassland or gorse scrub. A flora rich in species is present in the deeper crevices of the limestone pavements, which afford protection from grazing and conserve moisture. The filling of the crevices with humus leads finally to the development of grass heath corresponding to that of the scree slopes, which may later be invaded by bracken or juniper. Grazing pressure prevents the final succession to ash wood. Some statements referring to the wider distribution of certain species require correction. *Asplenium viride* is said not to be recorded in Ireland. It occurs in 30 per cent of the Irish vice-counties. *Dryas octopetala* is wrongly stated to occur on Ingleborough, whilst *Actæa spicata* is not, as stated, absent in Westmorland, but is recorded from the same limestone formation within six miles of the area studied.

Principles of Plant Geography

THE wide scope of plant geography and the varied methods of phytogeographical research are summarised by W. B. Turrill in a paper based on a series of lectures delivered at Westfield College (*Kew Bull.*, No. 5; 1939). The distribution of the main types of world vegetation is determined by climatic factors, principally temperature and precipitation, similar climates giving rise to plant communities with similar physiognomy, for example, the Mediterranean macchie and Californian chaparral. The distributional area of cultivated crops is also a valuable indication of natural conditions, and the areas in which they show maximum diversity have been used to determine their centres of origin. Distribution of the taxonomic units is discussed under physiographic, climatic, edaphic, biotic and historical headings. Other "inherent and miscellaneous" factors which influence distribution are cytogenetics (the distribution of polyploids, for example, often differs from that of diploids), plasticity of species, structural adaptations permitting survival of plants during unfavourable seasons, seed and fruit dispersal and seed setting. The last includes internal and external factors such as carbohydrate-nitrogen ratios, photoperiodism, pollination mechanisms, environmental control of seed ripening and cytogenetic factors for fertility and sterility. Brief reference is made to the determination of past and present migration routes and the theories of continental drift, age and area, and tolerance.

Hot Water Treatment of Iris Bulbs

IT is now a standard practice to heat most kinds of bulbs for three hours in water at 110° F. to combat attacks of eelworm. Iris bulbs have not usually been subject to the pest, but W. Buddin recently described a considerable attack of this plant by the stem eelworm *Anguillulina dipsaci* (*J. Roy. Hort. Soc.*, **64**, Pt. 9; September 1939). He applied the usual heat treatment for the comparatively short period of 50 min.; but even this slight operation had the unfortunate result of diminishing the flowering capacity of the bulbs. Exposure to the hot water for 25 min. had little effect upon the bloom, but was of doubtful value for control of the pest. It remains to find a critical length of treatment between 25 and 50 min., where the pest will be controlled, and the flowering not markedly reduced. Lowering of the floral vigour appears to be a direct lethal effect of the hot water, for increased exposure killed the vegetative parts also.

Spiral Structure in *Osmunda regalis*

I. MANTON (*Phil. Trans. Roy. Soc.*, B, **230**, 179–215; 1939) shows that the chromosomes of *Osmunda regalis* provide excellent material for the analysis of chromosome behaviour. The haploid number of chromosomes is 22 and all have terminal or subterminal centromeres and are similar in size. The number of coils at the first meiotic division is 4, at the second meiotic division is 8 and during mitosis is between 12 and 16. The coils are in equilibrium and exhibit no signs of torsional strain during meiosis. The author is of the view that the chromosomes exhibit high elasticity. Measurements indicate that the chromosome length remains constant throughout mitosis, but that at leptotene the thread is about 50 per cent longer, and at first meiotic metaphase 33–50 per cent shorter, than at mitosis. A hypothesis utilizing the apparent similarity to a proteinaceous elastic fibre in the α, β and supercontracted state suggests that the straightening of the molecular contractions at leptotene is a causal factor in chromosome-pairing.

Genetic Construction in Triticum

L. SMITH (Univ. Miss. Research Bull., 298; 1939) describes 56 mutants resulting from the X-raying of *Triticum monococcum* var. *vulgare* and var. *flavescens*. Only 9 of these 56 viable mutants had been found in untreated material. Among the genes were some which controlled the development of chlorophyll, of anthers and sporogenesis, while others influenced colour, hairs, stiffness of leaf and other characters. Ninety-seven combinations of genes have shown that there was no linkage between them, while nine pairs are closely linked, four (involving six genes) being very closely linked.

Thermal Properties of Water and Steam

Two papers by N. S. Osborne, H. F. Stimson and D. C. Ginnings (*J. Res. Nat. Bureau of Standards*, **23**, 197, 261; 1939) describe measurements of the heat capacity and heat of evaporation of water in the range 0°–100° C., and the calculation of the thermal properties of saturated water and steam. The papers include a careful critical examination of previous work. The second paper contains extensive tables. It may be mentioned that the value for the latent heat of evaporation at 100° found is 2256·30 internat. joules per gm., and that the specific heat values accord better with the results of Rowland, Laby and Hercus, and Jaeger and von Steinwehr, than with those of Callendar and Barnes. The new data affect the accepted values of the saturation properties of water and steam in the whole range up to the critical region.

Vapour Pressures of Sulphuric Acid Solutions

SOLUTIONS of sulphuric acid should be suitable as standards in the isopiestic method of investigating the thermodynamic properties of aqueous solutions in the higher concentration range, and S. Shankman and A. R. Gordon (*J. Amer. Chem. Soc.*, **61**, 2370; 1939) describe some measurements of the vapour pressure of sulphuric acid solutions at 25° for concentrations of 2–23 molal by the static method. The results are in good agreement with previous vapour pressure measurements up to 8 molal, and with electromotive force measurements up to 3 molal. At higher concentrations the vapour pressure and electromotive force measurements are in definite disagreement. A possible explanation is that the cell reaction in the case of the electromotive force measurements is not that postulated. The authors have calculated the activity of the water and the activity coefficient of the acid at various round values of the concentrations.

Reinforced Concrete Research

THE eighth of the studies in reinforced concrete made at the Building Research Station (Dept. of Scientific and Industrial Research, Building Research Technical Paper No. 25. H.M. Stationery Office. 1*s*. 3*d*. net) deals with the strength and deformation of reinforced concrete slabs subjected to concentrated loading. Various tests were made on slabs, 6 ft. × 6 ft. × 4 in., 12 ft. × 6 ft. × 4 in. and 6 ft. × 9 in. × 4 in., the concrete mixture in each case being 1 : 2 : 4 by weight, water-cement ratio 0·62 by weight, giving a slump of 1 in. to 1¼ in. At low loads, before the incidence of cracking, the slabs deformed in accordance with the theory of the elastic homogeneous plate. After the incidence of cracking under higher loads, considerable redistribution of moments was apparent and the ultimate loads were about twice as great as the values calculated by the elastic theory for square slabs and 1¼ times in the case of rectangular slabs. Hence the design of reinforced concrete bridge deck slabs on the usual basis of the elastic theory is conservative for the case of point loading under static conditions, since the high theoretical stresses in the neighbourhood of the load are considerably reduced as a result of plastic deformation at high loads. While this conclusion bears the satisfactory inference that the theory is a safe basis of design, it has been pointed out that the mechanics of slab action after the incidence of cracking are so complex that no alternative method of design is at present suggested. It is also mentioned that in this investigation the deflections of the supporting beams were so small that they were considered as not seriously affecting the moment distributions. In practice, however, the yielding of the supporting beams may be of considerable importance in this respect.

INTERNATIONAL UNION OF GEODESY AND GEOPHYSICS

THE seventh General Assembly of the International Union of Geodesy and Geophysics was held at Washington, D.C., during the period September 4–15, 1939, after the declaration of war upon Germany by Great Britain and France, consequent upon the German invasion of Poland. It was therefore probably the last of the series of great international scientific conferences of the period following upon the War of 1914–18. The choice of Washington as the place of the seventh assembly was made at the sixth assembly, in Edinburgh, in 1936. At Washington the invitation of Norway to the Union, to hold its eighth assembly in that country, was formally accepted, for 1942 or as soon thereafter as conditions in Europe permit. The first five assemblies of the Union were held at Rome, Madrid, Prague, Stockholm and Lisbon.

On August 30, when the political crisis was already nearing its height, the president and secretary of the Union, Dr. D. la Cour (Denmark) and Brigadier H. St. J. L. Winterbotham (Great Britain), after consulting the American Organizing Committee and other colleagues then in Washington, cabled to all adhering organizations intimating that the assembly would be held, but that its activities would be confined to scientific matters only. This last decision was subject to the approval of the executive committee of the Union, and was later agreed to; it was made because many of the expected delegates would be absent from the assembly, either because, having crossed to America, they had been recalled (as was the case with the whole French delegation and many of the British delegates, including most of those in the service of the Government), or, having started, did not proceed to their destination (as happened to the delegation from Germany, with the exception of one member who had travelled earlier to Washington), or had cancelled their journey before leaving. The business thus excluded from the original agenda included the discussion of administrative matters and of the proposed amendments of statutes, and also the election of new officers and executive committees for the Union and its seven associations. The existing officers were continued, as an emergency measure, until such time as a postal ballot seems desirable and feasible. Hence, for the present, the above-mentioned officers of the Union continue in office, as also those of the associations, as follows (*P* = president, *S* = secretary): Geodesy: (*P.*) Meinesz (Holland); (*S.*) Perrier* (France). Seismology: (*P.*) Heck (U.S.A.); (*S.*) Rothé* (France). Meteorology: (*P.*) Chapman (Britain); (*S.*) Bjerknes (Norway). Magnetism: (*P.*) Fleming (U.S.A.); (*S.*) Goldie* (Britain). Oceanography: (*P.*) Helland-Hansen (Norway); (*S.*) Proudman (Britain). Volcanology: (*P.*) Michel-Lévy* (France); (*S.*) Signore* (Italy). Hydrology: (*P.*) Lütschy* (Switzerland); (*S.*) Diénert* (France).

The vice-president of the Association of Hydrology, Prof. Slettenmark (Sweden), was present and presided over its meetings; the Association of Volcanology was entirely without officers present, and Dr. L. H. Adams (U.S.A.) was chosen as acting president.

Brigadier Winterbotham returned to England before the assembly opened, and Dr. W. Bowie (president of the Union at the Edinburgh Assembly) was chosen as acting general secretary of the Union; the work of the five absent secretaries of Associations was also undertaken by American delegates.

At present, about thirty-two countries adhere to the Union, and twenty of these were represented at Washington (Argentine, Belgium, Canada, Chile, Columbia, Denmark, Eire, Finland, Germany, Great Britain, Greece, Holland, Japan, Mexico, Norway, Poland, Rumania, Sweden, Switzerland and the U.S.A.). Visitors were present also from Bulgaria, Dominica, Hungary, India, the Philippines and Venezuela (non-member States). The United States naturally provided the largest section of members present, numbering approximately three hundred (with a hundred non-members); the number of other members present was about ninety-five (with about twenty-five non-members); thus the Assembly was one of the largest yet held. The absence of French and Italian delegates (and Russian visitors, as at Edinburgh) was much regretted.

In accordance with the decision not to discuss new administrative questions, the associations adopted no schemes involving new expenditure, and agreed to continue their financial management and programmes along the lines heretofore followed, so far as the available funds allow. Fortunately, the Union (and some of the associations in addition) has accumulated a certain reserve of unexpended money, and with its aid it is hoped that, despite the probable reduction of subscriptions accruing during the next year or two, the work of the Union and its associations can to some extent be continued until peace is restored.

The interest of the United States Government in the Assembly was shown not only by the financial provision which (with other assistance) enabled the American organizing committee (president, Dr. R. M. Field, secretary, Dr. J. A. Fleming) to make the excellent arrangements that helped so much towards the efficient conduct of the meetings. The Government, which during the development of the crisis clearly indicated its wish that the Assembly should be held, showed its good will also by an address of welcome from Mr. Cordell Hull, Secretary of State, at the opening meeting of the Union; moreover, the President, Mr. F. D. Roosevelt, received the Union officers and the presidents of the associations, together with Dr. Field, at the close of the Assembly. The closing words of Mr. Cordell Hull may be quoted here:

"If is my fervent hope, which the people of this country share, that the day may soon come when the statesmen of the world will take a leaf from the book of the scientists and solve international political problems in the same dignified and friendly spirit."

The scientific meetings of the Associations, and of the Union's Inter-Association Commission on Continental and Oceanic Structure (president Dr. Field), were held at the George Washington University, the new and older premises of which, generously placed at the Union's disposal, proved very satisfactory and convenient. The absence of administrative business enabled the full time of the Assembly to be devoted to scientific discussion, including several joint meetings between two or more associations, such as are rendered desirable by the ever more closely interwoven problems in the different departments of geophysics. At the end of the Assembly, when reports on the work of the seven associations and the Commission were presented, it was on all sides agreed that the scientific discussions had been most useful and successful, and that the Assembly had been as valuable as it was harmonious. Apart from the exchange and clarification of knowledge by the reading and discussion of scientific reports and papers (many of which had been circulated in full or in abstract beforehand), the associations were able to perform useful business in arranging for the continuance, in some cases with useful modifications or extensions, of international enterprises of geophysical importance, which they organize or support. Valuable and instructive scientific excursions, and visits to American scientific institutions, also took place during or before the Assembly.

---

* These officers were not present.

Personal meetings and discussions between fellow-workers in geophysics, from different countries, form another important contribution which such international assemblies afford to scientific progress. These were facilitated not only by the formal meetings, but also by the public and private hospitality which were dispensed to delegates, with the proverbial American warmth and generosity. Recollection of the kindness thus received from our American hosts will long be treasured in our memories.

The president and general secretary of the Union were honoured during the Assembly by the conferment of the doctorate of the George Washington University.

The Pan American Institute of Geography and History (director, Dr. P. C. Sánchey, Mexico) co-operated with the Union and held three meetings of its executive committee during the Assembly, at which many matters of interest to geodesists and geophysicists were discussed. S. Chapman.

WORK OF THE WATER POLLUTION RESEARCH BOARD

A PART of the programme arranged for the Conference of Delegates of Corresponding Societies during the Dundee meeting of the British Association was a discussion on river pollution. Sir Robert Robertson, chairman of the Water Pollution Board of the Department of Scientific and Industrial Research, had prepared a statement of the work of the Board for presentation to the discussion, from which the following account has been prepared. Details will be found in the reports of the Board published by H.M. Stationery Office.

Trade Effluents

Beet-sugar factory effluents. The evil due to these effluents can be avoided by passing the effluents through a biological filter, similar to that used on sewage disposal works. It is also practicable, however, to avoid the discharge of effluent by simple treatment by sedimentation, and addition of small quantities of lime so that the waters can be re-used in the factory.

Milk-factory effluent. This effluent, which is highly polluting and may be inimical to fish-life, since it removes dissolved oxygen from the water, has been demonstrated to be capable of complete purification by two methods: that of biological filtration, in which two percolating filters in series are employed, and the sequence of the two filters is periodically changed, and by the activated sludge process. The former method has been adopted in a number of factories. Fish can live in the treated effluents.

Studies of River Pollution

The River Tees. A river was chosen which is substantially unpolluted in its upper reaches, then polluted by sewage from a large town, and finally contaminated by sewage and trade effluents in its estuary. The Tees was formerly an important salmon river; it was found that in their progress down the Tees to the sea the smolts were poisoned in thousands. There has been no study made of a river's life-history so intensive, from the different aspects, chemical, biological, and hydrographical. In the non-tidal reaches the effects of sewage were studied on the chemical composition, and animal and vegetable life of the river, and on the seasonal changes with respect to the self-purification of the river. Similarly, in the estuary, these effects were observed on the composition of the water and estuarine life. An interesting conclusion was reached that the hitherto unsuspected cause of the death of smolts was due to cyanide from the coke-ovens; and methods of avoiding this were suggested, and to some extent have been adopted. This intensive study of a river from source to sea may be taken as an authoritative model for future investigations of other rivers.

The Mersey Estuary. Possibly as a result of its successful investigation of the River Tees, the Board was asked to carry out an investigation on the effect of the discharge of crude sewage from Liverpool and other towns in the district on the presumed silting-up of the estuary of the Mersey. This work, on which a comprehensive report has been made, involved nearly four years investigations by hydrographers, chemists, and biologists, and its findings, which are unequivocal, have been accepted by the interested bodies. It was found that the volume of the estuary is subject to periodical changes, but that the alleged shrinkage in the volume and hardening of the bed could not be attributed to the discharge of sewage into the estuary.

Water Supply

Two aspects of water supply have engaged the attention of the Board: the base-exchange process for softening water, and the question of prevention of contamination of drinking water by lead.

Base-exchange process. The effect of the various substances used for this process has been examined, and quantitative determinations have been made of the efficiency of the substances on the market, as well as of others, including treated natural clays. A remarkable discovery has been made whereby suitably prepared artificial resins can be used to remove both acidic and basic radicals from water.

Prevention of contamination by lead. A study of plumbo-solvency is being made with the object of improving large-scale methods of treatment of water. In the meantime, an apparatus has been evolved which on being introduced into a water circuit enables a quantitative measure of the lead present in the water to be obtained.

Sewage Purification

As fundamental knowledge was wanting as to the mechanism of methods of treating sewage, such as the activated sludge process, two groups of workers have been engaged on the chemistry and biology of this problem.

The effect of the air-bubbles, which are an essential part of this process, has been examined by chemical and physico-chemical methods, and the changes which occur in the nitrogen and carbon compounds found in sewage and sewage-sludge have been studied in conjunction with the enzymic activity of bacterial cells.

ROAD DEVELOPMENT IN THE UNITED STATES

Mr. E. L. Leeming, an expert on road construction, has given a description in *Roads and Road Construction*, of October 2, of a motor journey he made recently across the United States from Washington to San Francisco, along the Lincoln Highway. This road is now practically completed.

The first thing which strikes the eye of a road engineer, or a road user, when 'docking' at New York, is the sight of the motor traffic speeding along the overhead 'express highway' parallel with the Hudson River and linking the busiest parts of 'downtown' with Riverside Drive, Bronx and other suburbs. For the rapid movement of people, this artery is just as important to the city as the underground railways are. In Washington, since the economic blizzard of 1929, considerable transformation has taken place. Where streets are wide, many things are possible in the way of accommodating traffic. There is room for parking at the side or in the centre, and it is possible to construct an underpass of one road relative to another. Mr. Leeming saw a scheme of this kind in progress; one road is being carried beneath the other, while the surface of the junction is being arranged as a circle to link the connecting roads.

The Lincoln Highway connects the east coast at New York, where it passes beneath the Hudson River by the new Lincoln tunnel, with the Pacific coast near Portland. The road touches Philadelphia, Pittsburgh, Fort Wayne, south of Chicago, Cedar Rapids (Iowa), thence crossing Nebraska, Wyoming, Idaho and Oregon. At Wyoming the road crosses the 'continental divide' at a height of about 7,000 feet. At Salt Lake City he left the Lincoln Highway (U.S.30) and travelled by U.S.40 to San Francisco. Between Nebraska and Wyoming his average speed was 55 m.p.h. in his Studebaker car and his longest day's run was 610 miles. With daily mileages of 500–600, the number of restrictions or hazards are few. Cyclists and pedestrians are entirely absent, while horse vehicles are very rare.

Some curious notices were observed: "Danger, slippery, beware crickets" (meaning dead grasshoppers). In some of the villages, signs were noticed, such as, "Stop when pedestrians are on the crosswalk", "No overtaking for 700 feet", and so on. Good work is being done in the States in regard to 'safety first' measures by organizing schoolchildren. Selected children are trained as leaders to act as traffic police for the purpose of conducting schoolchildren across the roads to and from school. They carry signs indicating "Stop", and every motorist obeys them. Besides preventing children from being run down on the road, it teaches them to observe habits of 'safety first'. In Salt Lake City, where wide streets occur, parking is arranged with the aid of a special meter mounted on a pedestal opposite each vehicle parked on the slant. This meter is operated by placing a nickel (2½*d.*) for half an hour's parking, two nickels or one dime for an hour, and two dimes for two hours. Within these periods an indicator finger is visible at the top of the meter. The meters are only employed between the hours of 9 a.m. and 6 p.m.

Mr. Leeming's journey back from the Pacific coast to New York was made by air over a route covering the Boulder Dam, Grand Canyon, Texas, Kansas City, St. Louis and Pittsburg. This trip takes about 18 hours flying time, but compared with the journey by road, one does not acquire any intimate knowledge of the continent. The author strongly recommends a road journey across from east to west, by one of the arterial routes, U.S.30, U.S.40 or U.S.50. If it is not practical to hire or share a car, the Greyhound, a motor-bus service, is always running. These buses travel over the whole of the States, day and night, and one can sleep on them in very comfortable reclining chairs, if time has to be saved. The cost appears to be much less than that of the rail services. While the latter cost 90 dollars return from New York to San Francisco (without extras), the bus services cost about 65 dollars (about £14) for some 6,000 miles. These buses travel along the highways at about 50–60 m.p.h. and make very good progress.

Some indication of the programme of road development which is likely to be followed in the future is given in the General Motors Exhibition at the New York World Fair. Before making the tour, on the moving chairs of the panorama depicting the highways of America in 1940 gradually changing into the highways of 1960, you are shown a large map of the United States on the ceiling. By an arrangement of the lighting the existing roads are replaced by the new system of modern highroads which will cover the whole continent. Mr. Leeming was informed in Washington that there is enough road development work progressing in the States to keep them busy for the next two generations. Taking into account the remarkable progress which America has already made in road planning, bridge construction and the provision of flyover junctions, he has no doubt that the scheme outlined at the World Fair will be brought to fruition within the period contemplated.

SCIENCE NEWS A CENTURY AGO

Artesian Well in Paris

In the *Athenæum* of October 26, 1839, it is stated that: "At a late sitting of the Academy of Sciences M. Arago stated that he had that morning been making some thermometrical experiments at the artesian well at Grenelle, in order to ascertain the temperature at the depth which had already been attained, viz., 483 metres or 1584 feet. When the workmen had reached 466 metres the chalk was of a green colour, indicating the proximity of water. Since then the chalk had become mixed with clay, and of a dark colour, a still stronger indication that the sheet of water which it intended to meet is near. M. Arago used the thermometer of M. Walferdin, and after having taken all the precautions in order that the pressure which at such a height is equal to 50 atmospheres would not injure the bulb, six thermometers of the same kind were successively let down to a depth of 481 metres, care having been taken not to lower them until 36 hours had elapsed since the boring, in order that the heat which this work might have communicated should have subsided. The thermometers were left in the well for thirty-six hours. The heat at this depth was 27° of Réaumur, or 92¾° of Fahrenheit, being about 23 metres for each degree of temperature. M. Arago expressed a hope that no water might be found for a hundred metres more, as in that case there would be a permanent hot spring at the very gates of Paris."

The well was ultimately driven to a depth of 547 metres. A monument which existed at this spot was demolished in 1904 and a statue of Pasteur erected in its place.

Dye-Wood

This issue of the *Athenæum* of October 26, 1839, contains the following note: "A method of extracting the colouring matter from wood has been lately employed by a M. Besseyre with much success. He first reduces the woods to very small divisions, and then immediately places them in a closed vessel exposed to a current of steam. When the whole has attained 80 degrees of heat, it is uncovered and watered with several pints of cold water. By means of a tap below the condensed liquid is drawn off, and thrown back upon the chips, and the operation is repeated until the dye has acquired sufficient strength."

Edward Cowper at King's College, London

"On Monday last," said the *Mechanics' Magazine* of October 26, 1839, "a new and very important class of manufacturing art and machinery was opened to the students of this institution by Mr. Edward Cowper." The objects of the lectures and instruction were to familiarize students with machinery in actual use, and students were to make experiments themselves and also visit factories and works accompanied by the lecturer.

Edward Cowper, who was born in 1790 and died in 1852, was well known for his important inventions in connexion with printing machinery. With Augustus Applegarth (1790–1871) in 1827 he invented the four-cylinder machine which superseded the Koenig machine for printing *The Times*. His son, Edward Alfred Cowper (1820–93), the inventor of the hot-blast stove, was in 1880–81 president of the Institution of Mechanical Engineers.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant I in the Directorate of Communications Development—The Under-Secretary of State, Air Ministry, Dept. ZA. (B.127), Harrogate, Yorks (quoting B.403) (October 27).

Borough Engineer and Surveyor of the Metropolitan Borough of Stepney—The Town Clerk, Municipal Offices, Raine Street, E.1. (October 30).

Lecturer in Pharmacy in the Department of Chemistry of the Witwatersrand Technical College, Johannesburg—Frank Ross and Co., 9 Fenchurch Avenue, E.C.3 (November 1).

Professor of Chemistry and a Professor of Biochemistry—The Registrar, Indian Institute of Science, Bangalore, India (December 15).

Lecturer (Woman) in Mathematics—The Principal, Training College, Lincoln.

Assistants Grade I (Ref. A.001), Assistants Grade II (Ref. A.002), and Assistants Grade III (Ref. A.003)—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants.

ANTHROPOLOGICAL STUDIES IN INDIA

ALTHOUGH India offers in its aboriginal tribes and its diversity of peoples, languages, nd cultures a field exceptionally favourable for he development of anthropological studies, it annot be said that either Government authorities r those responsible for the direction of higher ducation have given them the encouragement hich such opportunities deserve. The valuable ork initiated by Sir Herbert Risley, and more articularly the Ethnographic Census, has been llowed to lapse, while until recently the universities have shown little inclination to include this nportant department of investigation within the ange of subjects in which they have provided acilities for research. It was, therefore, doubly nfortunate that for some considerable time nterest in Indian racial and cultural history was ostered by argument of a strongly tendentious haracter. The 'dry light' of pure science and isinterested research was, however, kept aflame y a small band of devoted enthusiasts, among hom the veteran anthropologist, Sarat Chandra Roy, will ever be held in honour. The establishment of a department of anthropology in the University of Calcutta, under the guidance of the ate Sir Asutosh Mookerjee, heralded the dawn of etter things, of which the work now carried on in the Universities of Bombay and Lucknow is an arnest.

Although the period which has elapsed since the nitiation of these facilities for anthropological tudy has been comparatively brief, it has sufficed o bring out certain difficulties which arise from he extent of the territory to be covered and the cattered distribution of the workers. Notable mong these shortcomings was a serious lack of o-ordination and co-operation in both research and instruction. It was felt that if research was to go forward with any measure of success, some centre at which workers from different parts of the country might meet for discussion and interchange of views was an imperative need. Only from full and free discussion, it was evident, would it be possible to formulate and give concrete shape to the problems which urgently call for investigation. The leading anthropologists of India thereupon decided to form an Indian Anthropological Institute, at which such meetings and discussions might take place. This was inaugurated in 1936, with Dr. J. H. Hutton as its first president, and a number of prominent anthropologists from different parts of India as the first members of its Council.

It is obvious that an institute of this character, founded and maintained on broad and catholic lines, should be in a position to exert a dominant influence in determining the future development of anthropological studies in India. It promises well that certain fields which are in urgent need of research, certain departments of investigation in which there are defects of organization urgently calling for reform, have already been indicated as demanding the consideration of the Institute's members, and it may be hoped that this will also arouse the interest of a wider public.

It was unfortunate that the foundation of the Institute took place only a short time before Dr. Hutton's retirement from the Civil Service and his departure from India. His many years' experience of ethnographical survey work among primitive peoples under the Government of Assam, as well as his organization and superintendence of the Census of India, 1931, gave him a knowledge of the problems of Indian ethnology which is unrivalled among anthropologists of to-day. This knowledge would have been of inestimable value in shaping and carrying out a policy of development in anthropological research in India. Dr. Hutton himself has not been without recognition of his responsibilities; and in his presidential address to the Institute, written towards the close of 1938 after his return to England, and in the nature of both an inaugural message and a valediction, he has wisely taken advantage of the opportunity thus offered him to suggest briefly the lines upon which the future work of the Institute might be carried on in relation to the organization of scientific study of the problems of anthropology in India.

No one is more fully aware than Dr. Hutton of the difficulties which lie in the way—the vast distances, and the differences of language, of temperament and even of script, which hinder co-operation among anthropological workers in India; but he suggests that these very difficulties make it all the more imperative that anthropologists should co-operate in a science "which can do more than any other branch of study to resolve into a homogeneous unit the racial, cultural, and temperamental diversities inevitable in the inhabitants of so great an area and such varying environments". Indeed, when he goes on to enumerate the subjects which urgently demand investigation, he points out how this very diversity in the peculiar social conditions of India provides a field more favourable to investigation than any other extant.

Nor is the question one of purely domestic concern to India alone, for, as Dr. Hutton justly adds, it may provide the solution of problems of world-wide application. Caste, for example, affords an unrivalled field for research, in that it preserves better than any other institution the pure genetic line and hence, owing to the wide and varied field of distribution, provides exceptional material for the study of the effect of different geographical and climatic environments on physical characters, on successive generations, and, in relation to the study of heredity, on individual aptitudes, on the inheritance of acquired characters, and a number of other cognate problems—in short, it opens up an opportunity for the full investigation of the effects of isolation on human groups, physically, psychologically and culturally. A further matter which is stressed, and is of more than local interest, is the need for detailed monographs on the aboriginal tribes and other groups, of which the lack severely circumscribe the study of Indian ethnology in the English universities.

Passing over other problems of research, upon which Dr. Hutton touches, as matters of technica rather than general interest, there is one question commended to the care and attention of th Institute which is vital for the future successfu pursuit of these studies. This is the supply o trained men, though in this connexion Dr. Hutton speaks more especially with reference to the need of museum work. If the efforts of the Institut in this direction are to be of any avail, it is scarcely necessary to point out that the closest co-operation with the universities must be secured, as well a an increased recognition among academic bodie that additional facilities for these studies wi have to be provided.

On one aspect of anthropological studies and research Dr. Hutton, in addressing a body o scientific men, did not dwell. In speaking of th need for a linguistic survey of languages south o the Godavery—a need upon which all anthropologists in India are agreed, and of which th lack is a serious bar to successful research—th need for ethnographical monographs on th aboriginal tribes, for the study of caste in it various aspects, and the like, the plea for study o all these problems might well be reinforced by stressing their practical bearing on the work o administration, and their value, if not indeed their vital necessity, for successful government under the new constitution, of peoples in whom racial, social and traditional differences run deep.

However much it may be felt that the study o the modern peoples of India falls short of th merits of its intrinsic interest, there are those wh think that the investigation of its past civilizations is in an even more parlous state. In communication, which appears in the first issu of the Institute's journal, Lieut.-Colonel D. H Gordon puts forward a grave indictment of thos who are responsible for the study of the pre- an proto-historic archæology of India, whether in India itself or outside, more especially since th retirement of Sir John Marshall from the archæological service.

It is evident that Colonel Gordon feels strongl that the position of archæological studies relatin to India calls for plain speaking. Nor does h stand alone. It is unnecessary here to enter int a detailed examination of Colonel Gordon' contentions in view of the report prepare y Sir Leonard Woolley on the results of his ecent inspection of the field organization and ccomplishment of archæological studies in India, digest of which is printed on page 758 of this ssue of NATURE. Colonel Gordon's views, indeed, nd further emphasis to Sir Leonard's criticisms. tringent though Sir Leonard's comment may be, specially in dealing with the work of the Archæoogical Department since the retirement of Sir ohn Marshall, and drastic as may be the changes dvocated, his recommendations are measures of eform, and not revolution. He admits the xcellence of the material in the members of the taff, and the learning and enthusiasm which net him everywhere; although the Department as been starved financially, the need of the noment is not the immediate expenditure of more noney, but training and experience in both fieldvork and the museum, combined with differentiation in function of the members of the staff. Hence follows the need for more complete co-operation between the universities and the Archæological Department inside India, and the participation in excavation and research of cientific and learned bodies from without.

Sir Leonard Woolley, as one of the foremost f practical archæologists who have worked n modern lines, has stressed fully the principle hat research on the grand scale, such as the importance of the cultural history of man in India demands, is an affair of the close adjustment of preliminary planning, field-work exactly carried out and precisely recorded, and the further analysis and study of the immediate results in the archæologist's laboratory—the museum—followed by early and widespread dissemination through prompt publication in appropriate form.

Opinion in India no doubt will be divided on Sir Leonard's recommendation that skilled assistance should be brought in from outside for a period to organize archæological studies. Yet in view of recent advances in technique and the wide field to be covered, especially in the earlier stages of prehistory, it would be difficult to ensure speedily a sound foundation for an Indian school of archæology by any other means at present.

For the moment, reforms must stand in abeyance; but even so it is not too soon to plan for the future. India is entering upon a new phase of its history. Could a more fitting memorial of that event be found than the institution of an organization for research which, in course of time, would build up worthily a comprehensive panorama of the development of the civilizations of India from the very earliest times down to the present day?

YOUTH AND NATIONAL SERVICE

The Needs of Youth

A Report made to King George's Jubilee Trust Fund. By Dr. A. E. Morgan. Pp. xi + 434 + 8 plates. (London: Oxford University Press, 1939.) 10s. net.

THE raising of the school-leaving age is only one of the factors which in recent years have directed special attention to the welfare of the adolescent. Reports from the Commissioners for the Special Areas have evinced concern at the effect of prolonged unemployment on the juvenile worker. and the situation has prompted attempts at amelioration such as the juvenile transference scheme and the junior instruction centres. Social surveys, such as the work of the Social Science Department of the University of Liverpool on population problems of new estates, have directed attention to educational and labour problems nvolved in the decline of the juvenile population, and to the need for industry to concern itself more closely with questions of recruitment. The annual reports of the Chief Inspector of Factories continue to emphasize the alarming proportion of preventable accidents among young workers, and the need for greater training and care for the young recruit to industry. The question has also been examined from the point of view of nutrition. as in the University of Bristol social survey of the standard of living in Bristol, or of general physical fitness from the point of view of the National Fitness Council, or the demands of national service. The present concern with the question of juvenile delinquency is yet a further factor, possibly less serious than some are inclined to fear.

In all such approaches, however, the welfare of the adolescent has been considered primarily from the point of view of the needs of the community if not rather of some special section of it. Even if we concede that the Education Act, 1936, was prompted mainly by a desire to safeguard the interests of the adolescent, it must be admitted that few, if any, authorities on education are satisfied with a measure which stops short of raising the school-leaving age to sixteen years, with provision for part-time training up to eighteen years. Moreover, however conscientiously the Act is administered, there has been evidence, in the applications for exemption, of failure once again to realize that the adolescents of the nation are ultimately more important than any industry.

The report which Dr. A. E. Morgan has recently prepared for the King George's Jubilee Trust Fund is thus opportune. Dr. Morgan reviews social, educational, industrial and recreational conditions in so far as they touch the adolescent, and his impartial and scientific survey, if it makes no claim to be a piece of sociological research, permits in any event an attempt at a coherent and comprehensive statement of the needs of youth in Great Britain to-day. Moreover, he contrives in his survey to give a picture of the life of youth in great industrial cities which is as welcome for its human appeal as for its challenge to constructive planning and resolute action.

One of the great merits of this survey is that it views the problem and the needs of youth as a part of the general problem of national welfare. Only on the bedrock of youth, Dr. Morgan asserts, can we lay the foundations of real national fitness. If under the specious plea of the needs of any particular industry, through the opposition of any vested interest, or even the demands of national defence, we allow the physique or morale of youth to be damaged, we are in danger of finding that not merely industry but also the nation as a whole is impoverished. There is a point beyond which the enforcement of economy at the expense of youth, even at the behest of national defence, may vitiate or nullify that last colossal effort.

The favourable comments on the first militiamen have often failed to direct attention to the debt owed to the extension of education to cover every kind of social service to the child. The schools are not only training the mind and body of the child, they are eradicating the results of the hectic industrialization of the nineteenth century. Extension of education to cover recreation, medical inspection and treatment, physical training and introduction to the use of leisure is only rectifying some of the great social injustices of the past.

If, for example, we see in the quality of mind and body revealed by recruits of the former militia some of the fruits of educational policy and expenditure, Dr. Morgan's book indicates how great the need still is, and the grave danger that in the years of unguided or unhelped adolescence, serious damage may be done alike to the physical, mental or moral development of youth which will prevent the full benefits of educational advance being reaped. Even on the educational side, the Education Act of 1936, however conscientiously administered, does not take us far enough. The nation cannot be said to be taking the care of its children seriously until the school-leaving age is raised to sixteen years. Even at sixteen we cannot afford to let the boy or girl step out of our care. The imminent decline in the adolescent population might well impel us now to take steps to prevent further invaluable human capital running to waste by insisting on a system of part-time continued education during the working day up to the age of eighteen years.

Next to this insistence on the need for providing for further education, at least part-time education, up to the age of eighteen, and for resisting any financial or industrial pressure that might endanger the interests of youth, Dr. Morgan stresses the need for much more careful provision for training and selection for a job and for dealing with the blind alley difficulty as well as with the serious problem of juvenile unemployment, so as to prevent both physical and moral deterioration. Similarly, juvenile delinquency is to be regarded as essentially an educational problem, the successful handling of which is an educational process.

Moreover, it is not merely in the actual training for a particular occupation and the selection of individuals for a job for which they are suited that closer attention to the needs of youth is required. Definite exclusion of youth from occupations which from their nature are unsuited requires extension. Much more could be done to reduce or prevent the alarming incidence of accidents among young persons entering industry. This involves not merely more careful training and instruction of the entrant to industry, and the placing of the accident-prone in jobs which are free from hazards; it involves also education of management and employers to a fuller sense of responsibility Nutrition, hygiene, medical care—these are all matters where extension of provisions or services for the school child to the young worker in his or her first trying and formative years in industry might be as sound an investment from the national point of view as it is socially desirable.

These are fields in which many scientific workers, by virtue of their managerial responsibilities or professional knowledge, may well be able to assist. When, however, Dr. Morgan proceeds to the discussion of the needs of youth in leisure and recreation and the means of meeting those needs, he raises a number of questions which are of the widest interest and significance. For all but a small minority who find expression in their vocation, workers as a whole look outside their labour for the expression of their lives. In our modern civilization, work has largely ceased to be an absorbing means of expression and is sought merely as the device by which we get the money wherewith to buy the things we desire. The hours of work are suffered for the sake of the reward which is to be reaped thereafter.

This salient factor, which the scientific worker is liable to overlook, gives special significance to the right use of leisure, above all when the tendency is to decrease the hours of work. Even adult education, for a quarter of a century claiming to be designed not for livelihood but for life, has emphasized this gulf which separates work and living. Moreover, with this search for real life outside work, leisure has largely become commercialized with debasement of artistic and other standards, while the functions of leisure have been widened and the need for its proper use enhanced.

The difficulties are increased by the confusion introduced by the false emphasis placed on freedom, particularly at a time when a democracy is especially nervous of anything which threatens the sacred principle of liberty. Ultimately, leisure must be a voluntary pastime. It is the means of expressing the vital aspect of human capacity, and as such must be free. Like any other human faculty, however, the capacity for recreation needs education, and the process of training involves compulsion. Again, while work may narrow with increasing specialization, the scope of leisure occupation is as wide as life itself, and even within the compulsory stage training must give the widest options.

These considerations lead Dr. Morgan to place his main emphasis on the need for leadership. This is a dominant factor in guiding and training youth so that its dormant faculties find normal and healthy expression, whether in physical recreation, in hobbies and pastimes, or whether, as in the 'Young Farmers' Clubs' in the union of vocational education with recreation, thus contributing to the solution of that major social problem of our time, the divorce of work and leisure. The value of the great majority of juvenile organizations, such as boys' and girls' clubs, depends on the right quality of leadership being available, and even in various community centres, facilities are being neglected and wasted for lack of leaders to manage and lead them. Moreover, when local authorities are actively assisting juvenile organizations and providing facilities, they are often unacquainted with the practice of other authorities. No one appears to have made a survey of the situation, and the Board of Education itself is without comprehensive information.

This matter of co-ordination and further survey of actual practice calls for further investigation, either by a group such as Political and Economic Planning or by the social science departments of the universities.

The general question of leadership, however, touches scientific workers generally even more clearly. It is not merely that the training which they have received carries with it certain social responsibilities, and that by virtue of their training the proportion of leaders should naturally be higher than in classes which have not been so highly trained or educated. The traditional source of supply for club leaders has been the young men and women of the better-to-do classes, whose sense of social responsibility urged them to devote time, and often money as well, to the welfare of the less privileged. The universal difficulty of recruiting enough help is an indication of a lack of social sense and responsibility to-day, and our educational system might well do more to impart such a sense of social responsibility. Leaders are in fact being recruited from every walk of life, but the significant fact to which Dr. Morgan directs attention is that leaders can now no longer be secured in sufficient numbers on a voluntary basis.

At present, the number of paid leaders is small, but boys' clubs must face the fact they will depend more and more on professional service, and the practical problem is to ensure that it is of the right kind. The basic difficulty is that imposed by the limited financial resources of such clubs. A club leader should have had a good education and some professional training. Much is expected of such leaders, but rarely is a boys' club in a position to offer a salary of more than £200 a year.

Dr. Morgan insists that we must recognize that club leadership is a profession and must be remunerated properly if the right men are to be forthcoming. He suggests it is essentially educational, and that local education authorities might well be persuaded to make far more grants to the voluntary movements for this purpose. Recognizing that even with this help there are limitations to the remuneration which could be expected, he suggests that more could be done to make such work a stepping-stone or stage to other careers whether in teaching, in industrial welfare work, probation service and the like, where the experience gained should be an asset.

Certain obstacles would have to be overcome. Such work must receive full recognition in regard to security and pension rights. Closer attention must be given to the training of entrants for such positions, and in this the social science departments of the universities might well co-operate.

As this tendency develops, it might open up careers for those taking a diploma in social science or pursuing a short course of social research, provided they possessed the essential qualities of leadership.

Here are suggestions which should be welcome to many scientific workers who are turning their attention to social problems. For some of them the voluntary work which will long be required may offer an opportunity for the expression of their sense of social responsibility, and for maintaining or even raising the standard of leadership. Others may find a like opportunity in the social surveys and investigations which are still necessary to render further information available as a basis for the national action required. For all, however, there is the opportunity to assist by pressing for adequate attention to the problem by local and national educational authorities, by supporting with their active interest such work as is already being carried out in this field by the universities, by bringing sympathy and insight and creative thought to bear on the problems which the needs of youth present to-day. Nor should scientific workers be unmindful of their responsibility as citizens to protest against any hesitation by public authorities to exercise their powers of compulsion to stop certain abuses which at present, as Dr Morgan so clearly shows, are detrimental to both the health and morale of youth, and, in effect squander capital which grows the more precious in a time of emergency. R. Brightman.

PLANETS AND SUNSPOTS

Tidal Forces in the Sun's Corona due to Planets
By K. G. Meldahl. Pp. 14+7 plates. (Copenhagen: Berlingske Forlag, 1938.) n.p.

THE author of this work believes that radiation pressure on certain small particles in the corona should balance gravitation so closely that a 'sensitive layer' exists. If this is disturbed, it will undergo violent motion and probably ejection. The force likely to produce the disturbances is the tidal action due to the planets, and though this is too weak to cause any noticeable motion in the heavier, luminous portion of the sun's gases, nevertheless, as the hydrogen prominences appear at a level comparable in height to the altitude of the 'sensitive layer', it is important to seek for some connexion between the disturbances and tidal forces. Only five planets need be considered to contribute anything of importance to the tidal force—Mercury, Venus, Earth, Jupiter and Saturn. Mercury, though very small, must be taken into account because the tidal force varies inversely as the cube of the distance of the planet from the sun; Mars is neglected as its tidal force is only about 3 per cent that of the earth. The five tidal forces are added vectorially, the resultant vector giving the height h of the force wave running round the equator, and the main investigation is carried out on these lines.

The period of Mercury is close to 88 days, and for this reason diagrams of vectorial additions for every eleventh day are drawn from 1663 to 1966 to test for periodicities. It does not appear that the period of Jupiter or the longer secular period of the three inner planets taken together is concerned, but a period of 243 years is partly noticeable, and a multiple of this seems to be indicated.

Discussing the connexion between the diagrams and the observations of disturbances, the author directs attention to two important matters. (1) Where radiation pressure is not constant, an increase in it would drive out the previously balanced particles and bring heavier ones into floating equilibrium, thus facilitating disturbances in the lower layers of the corona. (2) If existing spots increase radiation locally, this provides the possibility for relatively smaller tidal forces to generate disturbances. It will be misleading to compare the periodicity of *observed* spots and group sizes with tidal forces; the latter should be compared with the *genesis* of spots, and the existing spots should generally show a lag.

The mechanism of spot creation is considered to be as follows: Gases of the sensitive layer rotating with the sun at a speed of about 2 km./sec. run through the tidal field of force. At times they encounter forces greater than those that permit quiescent motion, and there ensues a break-up into vortices such as hydrogen prominences. A detailed description is given for the appearances of spots with regard to certain physical features, but it is open to some doubt whether all these are fully explained by the supposed mechanism of spot creation.

The author predicted a number of disturbances recently, which have since been observed, and it is possible that he has opened the door for further investigation into the genesis of sunspots, auroras, magnetic storms, etc. If it is true, as he states, that prominences are started in the corona by external forces and that spots are the consequence a fruitful field for research lies in this realm.

M. D.

AQUATIC PLANTS OF INDIA AND BURMA

Hand-Book of the Common Water and Marsh Plants of India and Burma, 1936
By K. Biswas and C. C. Calder. (Health Bulletin No. 24: Malaria Bureau No. 11.) Pp. xiii + 140 + 38 plates. (Delhi: Manager of Publications, 1937.) Rs. 2.12 or 5*s*.

THE purpose of this book is to facilitate the field work of those associated with anti-malarial investigations of the breeding places of mosquitoes. It is obvious that a sound knowledge of the plant life found in those localities, their reactions to each other and their relations with the animal life in their surroundings is an important stage in this research.

Brief accounts of the bionomics of freshwater vegetation, general features of aquatic vegetation, periodicity of water plants, methods of control, precede the systematic enumeration of the plants likely to be encountered. The work is not exhaustive, but is intended only to comprise the commoner plants. Short descriptions of the 61 families, 126 genera and 220 species (including Cryptogams) are set out, together with practical keys for the determination of genera and species where necessary. A key to the families would have been helpful to those inexpert in systematic botany.

Six reproductions from photographs of aquatic habitats and line drawings of 157 of the species or varieties listed are appended. Comparison would have been made easier had the plants of the same family, or at least genus, been juxtaposed. Only in the case of the Cryptogams have the magnifications of the enlargements been stated.

The nomenclature is not in all cases that accepted nowadays by systematists: for example, *Herpestes Monniera* has been retained in place of *Bacopa Monniera* (L.) Wettst., and *Panicum muticum* is given preference over *Brachiaria mutica* (Forsk.) Stapf

There are a number of errors and omissions; many of these have been corrected in an addendum not bound up with the publication, but others have escaped: for example, at the foot of p. 7, "Whether this . . ." should read "Where this . ." and *Leersia hexandra* Sw., described on p. 100 and figured on Plate III, is omitted from the index.

The work, however, is generally good and should amply fulfil its object. C. E. C. Fischer.

SOME ASPECTS OF CHEMICAL ENGINEERING

A Practical Manual of Chemical Engineering
By Harold Tongue. Pp. xvi + 560. (London: Chapman and Hall, Ltd., 1939.) 36*s*. net.

A BOOK on chemical engineering published in England is welcome, even if only to show the growing interest in this subject. Mr. Tongue's work does more: it fills, as he claims, a gap in the literature, by dealing with the materials which modern science has placed at our disposal, and methods of using them. It is admittedly a compilation and, as such, it is bound to exhibit a certain lack of balance; for example, under the heading "Wood", with the exception of a table of the mechanical properties of a few American woods, redwood is the only material discussed. Under "Rubber", six pages have been transcribed verbatim from a well-known pamphlet, apparently without acknowledgment—no doubt a slip on the part of the author—and there are other abstracts which, although good in themselves, are often somewhat disconnected.

The chapters dealing with metals and alloys are excellent, and the only criticism which need be made is again a certain lack of co-ordination, the mass of isolated facts tending to produce a sense of confusion. Perhaps in a future edition the author would consider the introduction of a few phase diagrams to explain the interrelations of some of the alloy systems. Since space is important, details of welding procedure might be curtailed, and extraneous matter, such as the uses of platinum as a catalyst, omitted.

The following sections on pressure vessels and piping are up to the high standard which is to be expected from the author of "The Design and Construction of High-Pressure Chemical Plant", and they are followed by a useful chapter on heat insulation and an even more valuable summary of recent data on the economic utilization of power in works. This difficult subject is one which should have more attention than it frequently receives.

At this point the author appears to have realized that the book was becoming too large, and to have attempted the impossible task of crowding heat transfer and a few selected unit processes into two hundred pages. The result is unfortunate, for the theory is inadequate and a great deal of the remaining matter, although by no means uninteresting, is strongly suggestive of a collection of manufacturers' catalogues. In the section on heat transfer, reading is not made easier by the use of different symbols for the same quantity and, in the chapter on distillation, modern work such as that of Kirschbaum is not mentioned. Under "Filtration", there are no fundamental principles at all. In short, in contrast to the earlier chapters, this part of the book contains little that is not to be found in standard textbooks. It would have been better omitted, or, alternatively, expanded into a second volume dealing not only with the plant itself, but also with recent research into fundamentals, which is becoming daily more important for the purpose of design

Any defects in the second half, and they are only defects of omission, are more than compensated by the earlier chapters, which presen in a handy form a summary of valuable information collected from sources which are not always readily accessible. As a volume of reference the work should find a place in the library of every chemical engineer. H. E. W.

APPLIED MECHANICS

Proceedings of the Fifth International Congress for Applied Mechanics

Held at Harvard University and the Massachusetts Institute of Technology, Cambridge, Mass., September 12–16, 1938. Edited by J. P. Den Hartog and H. Peters. Pp. xxxii+748. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1939.) 30*s*. net.

THIS account of the work of the Fifth International Congress for Applied Mechanics is contained in a volume of 748 pages preceded by preliminary matter including the list of the four hundred members of the Congress. The proceedings consist of general lectures and short papers of about six pages, divided among three groups.

The first group deals with Elasticity and the Properties of Materials. The general lectures by Hardy Cross, Joseph Pérès and F. Körber are reported in full and are followed by forty-four papers about equally divided between theory and experiment. Obviously no summary could do justice to the variety of topics here treated, so we select for special mention, on account of its historical interest, a paper by Hetenyi on photo-elastic studies of three-dimensional problems. In 1850 Clerk Maxwell observed that, if isinglass is loaded at an elevated temperature, after cooling and removal of the load it exhibits, in polarized light, permanent fringes which correspond to an elastic stress condition. Maxwell also concluded that there could not be actual stresses present in the annealed specimen, from which conclusion it would follow that slicing the piece should not change the fringe pattern. From an examination of the slices the stress distribution in a three-dimensional model could be inferred. This final step was not taken until 1935. The paper gives experimental evidence justifying the method of slicing together with some interesting photographs.

The second group, Fluid Mechanics, begins with general lectures by C. H. Chatfield, H. U. Sverdrup and G. I. Taylor, followed by sixty-two papers. The numerical comparison with the first group throws an interesting light on the relative trend of present day research. Not only so, but of the sixty-two papers, twenty-four deal with turbulence and related problems; indeed, a turbulence symposium was a feature of the Congress. In this group we select for special mention the paper by Norbert Wiener on "The Use of Statistical Theory in the Study of Turbulence". Behind the seeming innocence of this title there lies in this paper the beginning of a more general and systematic method of attacking the important problem of turbulence. The basic theorem is an extension by Wiener of the original ergodic theorem of Birkhoff to include the equi-measure transformation corresponding to the translation groups in space. The importance of this theorem is that it permits us to translate averages over all systems of an ensemble into averages over all points of space for a given system in the ensemble. This theorem, together with the definition of certain specific ensembles which can be described in detail, and for which every average can be computed, would appear to form a firmer foundation for the examination of turbulence than any which has hitherto been suggested. To complete the picture the abandonment of the hypothesis of the continuous medium will probably be found necessary.

The book concludes with seventeen papers on dynamics and an appendix. The whole volume has been reproduced from typescript. There may be some good reason for preferring this method to ordinary print, but there can be no question that the ragged margins inherent in typescript and the handwritten mathematical symbols are not things of beauty. Nevertheless the volume does give a cross-section of modern research in applied mechanics and is therefore worthy of serious attention. L. M. M-T.

METAMORPHISM AND IGNEOUS ACTION[*]

By Prof. H. H. Read, F.R.S.,
Imperial College of Science and Technology, London

THE consideration of the relation between metamorphism and igneous action, which forms the subject of Prof. H. H. Read's presidential address to Section C (Geology), falls into two parts. First, a brief historical summary of the peculiarly national contributions serves to display the wide divergences in opinion on this question. The views of the Rosenbusch school of pure thermal metamorphism are contrasted with the imbibition notions of the French, and the work of Becke of Vienna, the Swiss, Sederholm of Finland and the Americans is reviewed. The classic investigations of George Barrow on zones of progressive regional metamorphism in the Highlands north of Dundee and their causal relation to granitic injections are sympathetically summarized. In the second part of the address, a discussion is presented of the origin of regional metamorphism, that is, of the transformations which have affected large portions of the earth's crust.]

I first note the equivalence, according to Rosenbusch and others, of regional and dynamic metamorphism. The forerunner of the term dynamic metamorphism was Lossen's dislocation-metamorphism, a simple expression denoting a transormation genetically connected with dislocations of the crust. Lossen's old term would cover a arge class of phenomena, such as the dominantly mechanical breaking-down of rocks, cataclasis, mylonitization and the like, all connected with demonstrable dislocations. I propose to continue o use dislocation-metamorphism for this class of phenomena.

Rosenbusch, having replaced Lossen's excellent erm by his dynamic metamorphism, proceeded o make this the equivalent of regional metamorphism, and to regard orogenic pressure as its cause. Backed by the authority of Rosenbusch, dynamic metamorphism became fashionable, the dynamic aspect overshadowed all others and mountain-building movements could do all things requisite and necessary. It must be remembered, however, that many of the French were frankly sceptical; nevertheless, the notion of a metamorphism on a regional scale "induced in rocks because of their deformation" remains still a leading principle in many schools of metamorphic geology.

On the other hand, the emergence of ideas on a static or load metamorphism of regional extent, in which orogenic pressure is not a causal condition, indicates that all is not well with the supposed equivalence of dynamic and regional metamorphisms. Before discussing static metamorphism itself, I deal with some of the difficulties raised by this equivalence.

I mention certain facts commonly observed in regionally metamorphosed rocks but difficult to reconcile with the operation of pressures tangential to the earth's surface. One of the chief of these observations is the coincidence of schistosity and bedding. As metamorphic rocks showing this coincidence are often horizontal over great areas, the notion of static or load metamorphism has been put forward. But Daly has cited a score of regions where schistosity and bedding agree—in folded and horizontal rocks alike. These are the phenomena that Daly felt to be "truly inexplicable by pure dynamic metamorphism", an opinion with which I am in complete accord.

The preservation of original textures in rocks that have been completely recrystallized is a matter of common observation. There are innumerable examples of the preservation in regionally metamorphosed rocks of minute sedimentation-characters, such as graded bedding, current bedding, the interlamination of undisturbed, exceedingly thin, beds, and so forth—characters that should have been obliterated by the action of orogenic pressures. As an instance of how excellent this preservation may be, I may recall the successful use of current bedding and graded bedding in unravelling the stratigraphical sequence in the Grampian Highlands. An additional and telling example is the recognition of varved bedding in the metamorphic rocks of Finland and Canada. It seems to me that such details of original textures cannot possibly be preserved if the rocks in which they occur were metamorphosed "because of their deformation". I admit, of course, the operation of dynamic action in the production of various metamorphic rocks of low grade, but in these cases the original primary textures are completely obliterated. This obliteration in low-grade metamorphism and preservation in high-grade metamorphism of original textures shake my faith in the unity of the progressive series from the chlorite zone or epizone to zones of higher grade.

---

[*] From the presidential address prepared for Section C (Geology) of the British Association.

Whilst stress is admittedly the dominant factor in the production of low-grade metamorphic rocks, there is agreement that its effect is small in the higher grades, where the products of regional and thermal metamorphisms converge, high temperatures being in control. There is no correspondence between the degree of deformation and the metamorphic grade, unless it be one of the greater the deformation the lower the grade. In this connexion, I may cite the failure of experimental work, like that of Larsen and Bridgman, to produce minerals characteristic of rocks supposedly formed by dynamic metamorphism. Stress, by itself, is not enough.

No one can dispute the observed fact that regionally metamorphosed rocks are often more or less violently folded. The inference so often made that the metamorphism and the folding are coeval is not, however, always justified. It seems to me clear that most fold-structures in regionally metamorphosed rocks ante-date the crystallization, this being post-tectonic in the terminology of Sander.

It will be realized, I trust, that there are many features of regional metamorphism that are incompatible with dynamic action. The recognition of this has led to the invocation of static or load metamorphism, and I examine the validity of this notion.

One of the especial difficulties that has to be faced by advocates of a metamorphism due to the vertical pressure of the overlying beds is the existence of completely non-metamorphic rocks which have nevertheless been covered by an immense thickness of superincumbent strata.

This difficulty confronting static metamorphism has been tackled by Daly, who meets it by relaxing the rigidity of the doctrine of uniformitarianism. He admits that, compared with its proposed potency in Pre-Cambrian times, load-metamorphism must have been of relatively little importance in later geological eras. To account for this, he assumes that the earth's thermal gradient was steeper during the formation of the Pre-Cambrian so that regional metamorphism under a moderate cover was possible. I am not competent to discuss Daly's speculation, and I have only to state that I feel that the proposal does not strengthen the case for regional static metamorphism.

The idea of a metamorphism controlled by load, as such, fails to meet many other observations. I have space here only to cite the occurrence, in the eastern United States, of highly metamorphosed stratigraphically younger beds resting naturally on lowly metamorphosed stratigraphically older beds; of high-grade sillimanite-zone rocks overlying lower-grade rocks as in Sutherland and Norway; of the passage, in Banffshire, from slates to metamorphosed rocks containing andalusite garnet, cordierite, sillimanite and staurolite withi a half-mile of coast-section; of a similar narro restriction in the Barrovian zones as in Dutches County, New York. Load, by itself, is not enough.

The literature of regional metamorphism abound in references to the great depths within the crus at which such metamorphism takes place. Thes suggestions of great depths, however, carry n kind of conviction to my mind. On the contrary I consider that high-grade regionally metamorphosed rocks must have been formed in man areas under relatively little cover. Daly was o this opinion, too, and he was influenced thereb in his idea that thermal conditions were differen in Pre-Cambrian time from what they were i Palæozoic time. He pointed out that from Clarke' data it is possible to form a rough estimate of th total amount of rock eroded in geological time and that only a small portion of this amount can be assigned to Pre-Cambrian time. Of thi small portion, part is represented in the non metamorphic Pre-Cambrian sediments which li unconformably on the metamorphosed basement The several complexes of the basement were highl metamorphic before the denudations correspondin to the unconformities which separate them. Fron a consideration of these points, and of the grea volume of Pre-Cambrian rocks, Daly conclude that the average cover on the complexes at th time of their metamorphism was much less than 5,000 metres in thickness. Barrell came to similar conclusion by an argument based upon the amount of salt in the sea, and the erosion of the igneous rocks to give this. He decided tha Pre-Cambrian erosion had removed a cover of les than a mile in thickness.

Though these arguments may not appear altogether sound to some, still I suspect that th notion of the great depths of regional metamorphism flourishes because of the supposed necessit of carrying rocks *down* to be metamorphosed. suggest that as an alternative we should conside the possibility of bringing the metamorphosing agents *up*.

I next discuss certain aspects of the zona notion, especially in connexion with a depth control.

I note the development of ideas on depth-zone and, in connexion with static and load metamorphism, I direct attention to difficulties encountered in regarding grade of metamorphism a directly controlled by depth. Admittedly, metamorphism does often increase in grade with depth but, as I have said in another place, I personall find no difficulty in envisaging a metamorphism which increases laterally or vertically; I conside depth, as such, not to be a factor in metamorphism nd that if we are to retain a zonal notion, then he idea of depth-control must be completely disregarded.

The relation between the large-scale tectonics nd the metamorphic zones in the Highlands is a question which, in the present state of our knowedge, bristles with difficulties. The Cambridge School considers that the metamorphism is pre-ectonic, and that the metamorphic zones can be ecumbently folded. On the other hand, Bailey nd others regard the metamorphism as partly ontemporaneous with the folding. For my part, suggest that the metamorphism may be post-ectonic. Both in the Highlands and elsewhere it eems to me that the isograde lines are indeendent of both stratigraphical and tectonic arrangements, and I prefer to relate regional metamorphism not to load, nor to deformation, nor to tectonic or any other depth.

I have pointed out the destruction of sedimentary structures in low-grade metamorphism and their apparent perfect preservation in high-grade metamorphism. If these are valid observations, then it seems to me that the progressive series from slates to higher-grade rocks must break down, or, at least, that high-grade rocks were not necessarily at one stage of their career in the condition represented by the lowest-grade rocks of the zonal series. Low-grade rocks may once have been high-grade, but the reverse is not necessarily true.

(To be continued.)

REACTIONS OF ACCLIMATIZATION AND OF NON-ADAPTATION

By Prof. M. Piery and Prof. J. Enselme,
Faculty of Medicine, Lyons

UP to the present time, physiologists have been especially concerned with the cute effects of high altitudes or of acute mountain ickness. As a consequence of the work of Prof. Monge of Lima, who both discovered and studied hronic mountain sickness as manifested in human eings, we, in our turn, have investigated the xperimental effects of high altitudes on animals. We believe that in this way we may be able to discover more about the mechanism of adaptation f organisms to altitude, and thus explain the athogenesis of Carlos Monge's disease.

With this object in view, we studied the effects roduced in various animals by a sojourn of six months in the laboratory of the Jungfraujoch, at an altitude of 3457 metres. We have already described elsewhere the technical methods and detailed observations which we have made in his experiment. Here, our object is to give xpression to certain views which we hold relating o the adaptation of the animal organism to the ower atmospheric pressures of high altitudes.

The problem of the effects of altitude upon nimal organisms gains considerably in depth and nterest if, by exceeding certain limits which are usually accepted, we consider it from a more eneral point of view.

In order to do so, the following facts must first f all be taken into account:

(1) The problem constitutes a particular case f the much wider problem of adaptation in general; it is the case of adaptation to the lowering of atmospheric pressure.

(2) It consists of several biological stages which, like all adaptations, may be schematized as follows:

(*a*) A tissue forms the receptive element for the external influence. Sometimes this is the skin, sometimes the digestive organs and, in this particular case, the lungs.

(*b*) The effects there are carried by a transmission system into the innermost tissues and set up a connexion between the receptive tissue and the whole of the organism. This transmission system consists of two physiological pathways, a neuro-vegetative action, adrenergic or cholinergic, or alternatively in the form of an action of a chemical messenger.

(*c*) A system of tissue reception which affects the various organs and those elements of inter-tissue synthesis; namely, the glands of internal secretion.

(*d*) A mechanism of genetic transmission, the reaction of the genital elements.

(3) Furthermore, in the case of each one of these components, the following must be distinguished:

(*a*) The modifications which appear as direct effects of the climatic change: as, for example, the modification of the tissues by chemical or mechanical influences.

(*b*) A number of reactions which are not so easily explained and which are called defensive reactions because they permit of the survival of the tissues. These constitute the actual basis of the phenomena of adaptation.

(4) The adaptation thus effected constitutes a new form of state of the organism which, in order to return to its previous state, must pass once more through the same stages.

These principles set forth, we will now proceed to apply them to the problem with which we are concerned, namely, that of adaptation to the lower atmospheric pressure of high altitudes. And here, we propose to divide the subject as follows:

Effects of Reduced Pressure on an Organ Sensitive to Climatic Anomaly

Here, climatic anomaly is constituted by the drop in the partial tension both of the oxygen and of the carbon dioxide in the air inhaled; and consequently in the alveolar air. The sensitive organ here is the lung.

The effect of this lowering appears to be a congested state such as we have witnessed in rabbits and geese which have spent six months in the laboratory at the Jungfraujoch. This congested state is characterized by a decided vaso-dilatation of the inter-alveolar capillaries. A large number of alveoli contain red corpuscles, and some of them contain, in addition, alveolar cells in process of desquamation. These lesions have no characteristic localization. There is no indication either of inflammatory cells or of the presence of fibrin in the alveoli.

The importance of these lesions varies according to the subject. In order to estimate them to the best advantage we conducted, on one hand, a histological examination of the lungs; and, on the other, we administered doses of iron to the entire organism. The results given by the two methods appear to agree with one another.

These lesions appear to aggravate further the difficulties experienced by oxygen in passing through the walls of the pulmonary alveoli. Their action is of the same kind as that of the diminution of the partial tension of oxygen in the alveolar air. They thus appear to act in the same direction as the reduction of atmospheric pressure and to increase the disturbances which it evokes. In addition, we observed that these lesions actually lower the oxygen saturation of arterial blood.

On the other hand, a defence reaction which tends to correct the abnormal phenomena evoked by the lowering of pressure is observed. This defence reaction consists of an unfolding of those alveoli which have not, as yet, been utilized; and of a polypnœa which renews the alveolar air more rapidly and thus contributes to a slight rise in the partial tension of the oxygen in the alveoli.

Disturbances at the Level of the Systems o Transmission

We have already seen that it is convenient t distinguish two systems.

(1) The system of neuro-vegetative transmission responds to the excitation evoked by reductio of atmospheric pressure and to the lowering of th blood oxygen by tachycardia, which permits of more rapid circulation of arterial blood and consequently of transmission of oxygen. Furthermor a reflex produces a splenic reaction which throw a large number of red corpuscles, oxygen carrier into the circulation. These ensure the mos complete circulation of oxygen.

(2) The system of chemical messengers show two types of reaction:

(*a*) An inevitable chemical effect of the lowerin of the partial pressure of alveolar oxygen is th fall in the oxygen saturation of the blood. This in any event, represents a classical idea which w re-discovered in the case of the rabbits in th Jungfraujoch laboratory, among which the averag was 77, while that of the control animals was 91

Another result of the same type is the marke drop in the total quantity of carbon dioxide i the blood. Lowering of the partial pressure of th alveolar carbon dioxide has also been described and we found it again. Actually, our rabbit showed an average of 29·6 for total blood carbo dioxide, while the controls gave an average of 42·7

(*b*) The defensive reaction of the organism is shown by a hyperactivity of the hæmatopoietic centres, which throw a large number c corpuscles, usually of the smaller kind, into th circulation and thus increase the surface o absorption reserved for hæmoglobin. The averag number of red corpuscles in a rabbit is abou 4,300,000; in the experimental rabbits it increase to a total of 6,978,000. An important increase i the oxygen capacity of the blood ensues; an while among the animals experimented upon i Lyons this capacity was represented by an averag of 12, in those at the Jungfraujoch it increase to 19.

In another connexion, the lowering of th carbon dioxide of the blood effects a lowering c the alkaline reserves. Compensation for this i obtained by an increase of certain buffer system

Disturbances of the Tissues

Disturbances of the tissues are manifold. In general sense they correspond to the phenomen of anoxia and acapnia. The phenomena of anoxi are distinguished, in every part of the organism by chemical modifications, such as the lowerin of the basal metabolism and the increase c of lipides or of cholesterol. They become mor easily recognizable when they affect special organ

(1) We made a special study of muscle, and hile in rabbits generally we found equal amounts f muscle iron, in those animals which had been n the Jungfraujoch laboratory we observed a arked decrease in the quantity of the iron. We re of the opinion that during the first months of daptation, a diminution in exchanges, together ith a lowering of the iron content, takes place. his irregularity soon passes off Clinically peaking, muscular anoxia is expressed in the form f asthenia and disturbances of a painful nature.

(2) The liver also has occupied our attention o a large extent. In our rabbits, the iron increased. We are of the opinion that this constitutes a first efence reaction against anoxia, the iron playing e part of an active agent of oxidation. Hepatic noxia is expressed clinically by the characteristic gns of insufficiency of the organ.

(3) The heart very often gives rise to acute mptoms, and in our animals we observed, stologically, traces of sclerosis.

(4) Finally, a number of other organs are also fected, such as the nervous centres or the kidneys; ut histologically, in the case of our animals, no ions were visible.

Conclusions

In this preliminary study, we have considered e mechanisms of adaptation at an altitude of out 3,500 metres as observed during a sojourn six months' duration. We have observed the adual development of a certain number of these echanisms. The observations which we were le to make on the constitution of the blood have ly served to confirm data that had already come classical. On the other hand, the observaons which we were able to make on the tissues, ngs, muscle and liver, give rise to a number of w conceptions. For example, in the lung, phemena of congestion appear which seem to gravate the anoxæmia, while in the liver and muscles, variations in the iron content seem to be in accordance with adaptation to anoxia.

It remains now to distinguish among the facts which have been observed and described above; those which arise from a successful adaptation—that is to say, from successful acclimatization—and those which in the animal correspond to the chronic mountain sickness manifested in human beings.

In this connexion, non-adaptation to lowering of atmospheric pressure is accompanied by congestion and capillarization of the lungs, by a drop in the oxygen saturation of the blood, by a marked lowering of the total quantity of the carbon dioxide of the blood, by the diminution of the alkaline reserves, by the diminution in muscular iron, and finally, a light sclerosis of the myocardium. On the other hand, the phenomena of effective adaptation give rise to polypnœa, to the unfolding of the alveoli, to emphysema, to increased activity of the hæmatopoietic centres, to an increase in the oxygen capacity of the blood, to the growth of certain buffer systems and finally to an increase of iron in the liver.

Thus our analysis, both chemical and histological, results in arguments in favour of the idea of a complex response of the organism to anoxæmia and of the existence of manifold reactions of acclimatization. It now remains to apply to man the experimental observations which we have carried out on animals. This we hope to be able to do at some future date.

NUTRITION DURING WAR-TIME

By Sir John Boyd Orr, F.R.S.

THE new science of nutrition has raised issues which profoundly affect the economic and cial structure of the State. During the last few ars, the agricultural, trade, health and social pects of these issues have been studied by rious groups of investigators, and arrangements re made by the Division for the Social and ternational Relations of Science for a discussion the subject at the British Association meeting at Dundee on September 8. Owing to the outbreak of war, the discussion did not take place. The results of the investigations promoted by Government committees, research institutes and other organizations in recent years will now prove invaluable to those adjusting the national food supply to war needs.

These studies of the food position have clarified ideas. It is now common knowledge that a great deal of disease, ill-health and physical disability, which in the past were regarded as normal and inevitable, are due to faulty diet and, therefore, preventable. We now know the kind of diet needed for health. The British Medical Association standard was calculated to be good enough to prevent obvious clinical signs of malnutrition. According to the results of Sir William Crawford's survey, which agrees closely with the results of other investigations, there are nearly nine million of the population of Great Britain whose diet is below that standard. But there is a great difference between the mere absence of disease and full vigorous health, which is provided for in the higher standard of the League of Nations Nutrition Committee. The diet of nearly half the population does not come up to this higher standard. Quality of diet is correlated with income. Dietary and health surveys have shown that as family income falls the diet becomes worse, and ill-health and poor physique become more prevalent. The infant mortality rate is three times as high among the very poor as among the wealthy. The incidence of disease attributable to faulty diet is several times as high, and the average adult stature is three to four inches less.

In addition to poor diet, there are, of course, other factors associated with poverty, especially bad housing and psychological factors which affect health. It is difficult to assess the relative importance of these, but there is no doubt about their combined effect on health. As the Right Hon. Mr. Bruce has put it: "Poverty is directly correlated with ill-health, disease and premature death."

It used to be assumed that the poor represented an inferior strain of the population and that the high infantile mortality among the poor was Nature's salutary method of eliminating the unfit. This view, which would absolve us from doing anything to abolish poverty, is not supported by facts. Where the infantile mortality rate is highest, the survivors are of poorest physique and vice versa. The factors which make for high infantile mortality seem to be the same factors which make for ill-health and poor physique among the survivors. There is no doubt about the importance of heredity, but we cannot dogmatize about inherited difference in health and physical fitness between the well-to-do and the poor until environmental conditions affecting health and physique are comparable in both classes.

Of these environmental factors, nutrition seems to be of prime importance, because the results of feeding tests show that when the diet of the children of the poorer classes is improved, making it more like that of the well-to-do, the rate of growth of children approaches that of children of the well-to-do classes, and there is a noteworthy improvement in health and physique. In the la twenty-five years, there has been a remarkable im provement in the national dietary. Consumption 'protective' foods has increased by nearly fifty p cent; there has been an accompanying improv ment in national health and physique; infa mortality rate has fallen by nearly fifty per cent the gross forms of deficiency diseases, such rickets, are rapidly disappearing; deaths fro tuberculosis, resistance to which has increased b good diet, has been reduced by nearly fifty p cent; children leaving school to-day are two three inches taller than their parents at the sa age. What has been done shows how easily li could be saved and life and happiness increase It affords complete justification for the publ health and social services which have made t 'protective' foods, especially milk, available, fr or at reduced prices, to necessitous mothers a children.

Although such a remarkable improvement h taken place, we are still far from our goal, whi is an adequate diet for every member of the co munity, however poor. In the United States, t British Dominions and other countries, whe investigations have been done, the position is n markedly dissimilar to what it is in Great Britai National health and physique, especially of t poorer classes, is far below what it would be the new knowledge of nutrition were fully applie This opens up a glorious vista for the futu Even in the most advanced countries, man h not yet attained his full capacity for health a physical fitness. We have the knowledge and can provide the means for a further great advan in human welfare. Rapid improvements have be made in Great Britain and elsewhere, and, in atmosphere of increasing good will, schemes we maturing for adjusting national food policies provide diets for the whole community on t standard now known to be necessary for healt

It would be disastrous if this work were push into the background as being of minor importan in war-time. As a matter of fact, the nutriti problem becomes even more urgent in war. T will continue to be a war of nerves, and the iss may well depend upon whether or not the peo are able to withstand the physical and men strain of war. Malnutrition, due to lack of 'p tective' foods, leads to lack of capacity for s tained physical and mental effort, apathy a despondency, all factors which make for fear and spirit of defeatism. For maintaining the will victory in this war for liberty, the quality of t national diet is as important as the quantity. O aim should be to accelerate the remarka improvement in diet and accompanying impro ment in health of the last few years.

Fortunately, the food policy for war is the same as the food policy needed for peace, namely, ncreased production and consumption of 'protective' foods. Food defence, in addition to providing stores of wheat, sugar, fats and other foods, and organizing distribution and rationing, must consider the question of what additional foodstuffs agriculture must produce to maintain and improve the national diet. Yield of protein, vitamins and minerals per acre must be considered as well as yield of calories.

This is one of the war measures for which we need not grudge expense. A war food policy, designed to increase the health and vigour of the population and to adjust agriculture and trade in foods to the needs of the population, will leave a national asset which will be invaluable in the reconstruction period after the war for world freedom is won. There is here a great opportunity for the Ministry of Food to co-operate with the Ministries of Health and Agriculture, involving a national policy which will help to win the war and have at the end of it a vigorous race ready to take a lead in post-war world reconstruction.

OBITUARIES

Prof. Sigmund Freud, For. Mem. R.S.

By the death of Sigmund Freud, the world of psychology has lost its best-known figure. Born in 1856 of Jewish parents in Moravia, he decided at an early age to take up the study of medicine. While still in the twenties he went to Paris to study psychiatry under Charcot; and at the age of thirty-one returned to Vienna, where he spent the greater part of his life.

To the scientific world, Freud's name first became known through researches on the nervous system. But while working in France he became strongly mpressed with a notion that had already been taking shape in his own mind, the notion, namely, that in the existing state of physiological knowledge nervous disorders are best investigated, not by looking for physical causes, but by studying mental causes, particularly emotional conflict and repression. In his early work as a neurologist he began by applying the methods of hypnosis which he had learnt in Paris. Gradually, however, he abandoned this approach for a more effective technique, to which he gave the name of psycho-analysis. The method, suggested it would seem by the work of Wundt and Galton on free association, threw an unexpected light on symptoms and processes which the patient's answers to the direct questioning of the consultant were apt to leave wholly obscure or even to misinterpret. To-day the term psycho-analysis is applied, not merely to the method, but also to the vast body of doctrine built up with its aid by Freud and his disciples: it might be loosely defined as the empirical study of unconscious mental processes.

The essential framework of Freud's views was laid down in his early writings on hysteria nearly forty years ago. He never hesitated to modify or expand his hypotheses; but in the main his later publications, running to something like two hundred books and articles, consist in suggestive and provocative applications of these leading ideas and principles to various branches of psychology. From the study of major nervous disorders, he proceeded to minor abnormalities that characterize mental life for every one of us—dreams, lapses of memory, slips of the tongue, and the like; and thus showed in concrete detail how the scientific study of the exaggerated reactions of pathological cases may explain the more puzzling or neglected phenomena of normal persons. From this he turned to other fields. Art, poetry, religion, crime, mythology, anthropology—nearly every sphere of life was illuminated by the inquiries he attempted and the principles that he applied.

Freud was, indeed, one of the boldest and most original of thinkers. Nevertheless, the isolated items in his theories were by no means so novel as is popularly supposed. Both in Great Britain and in America a strong reaction against the intellectualistic psychologies of the nineteenth century had already set in: James and Stout had emphasized the need for a more dynamic psychology; McDougall had urged the importance of unconscious motives, particularly in the instinctive and emotional life; Janet had emphasized the importance of dissociation in mental disorder and disease; Havelock Ellis had attempted a scientific study both of dreams and of sex. Freud's own great achievement was perhaps to incorporate what was most fruitful in these ideas in a single, striking, unifying system, and to collect a vast amount of empirical data from a wide variety of sources, all illustrating much the same fundamental mechanisms of the mind.

Though widely read in psychological literature—English and American as well as German and French—Freud never cared to bring his own views into line with academic tradition. This led at first to wide misunderstanding, but was equally a condition of his fresh and revolutionary outlook. In Great Britain, as elsewhere, his bold speculations and even bolder expression of them aroused initial opposition. But a wide experience of nervous disorders during the War of 1914–18 quickly convinced workers like Rivers, Myers and McDougall that there was a most important foundation of truth in the novel doctrines that Freud had advanced. It was perhaps the very antagonism aroused by his frank utterances that in the end gave a wide publicity to the new attitude towards mental disorder, and brought home to the medical man what the psychologist had long urged—the need for considering not merely the physical but also the mental, emotional, and social condition of his patients.

CYRIL BURT.

Prof. Harvey Cushing, C.B., For. Mem. R.S.

THE death of Prof. Harvey Cushing on October 7 at the age of seventy years removes from the world of medicine its greatest ornament since William Osler. Cushing and Osler had much in common. Each had tireless energy, unbounded enthusiasm, and that great gift of making friends and keeping them. The love of all that was good in literature and of the classics of medicine was as much a characteristic of Cushing as it was of Osler.

Born of a Massachusetts family which had migrated in the early part of the nineteenth century to the Western Reserve, now part of the State of Ohio, Harvey Cushing was the ninth child of a Cleveland doctor whose father and grandfather before him had practised the art of healing. If on his father's side he had inherited a love of medicine, he obtained an almost equal love of literature from his mother, whose forebears had migrated from Connecticut to carry Yale learning to the new country in the west. It was inevitable that he should have graduated in arts from Yale and in medicine from Harvard.

The attraction of Johns Hopkins Hospital was too strong to be resisted by the young graduate in medicine, and there began his life-long friendship with Osler and his apprenticeship in surgery under Halstead. During his early days at Baltimore, he commenced his experimental work, which he continued in Europe under Sherrington, Horsley, Mosso, Kronecker and Kocher. This training was to fit him to be a neuro-surgeon. In the early stages of his surgical career at Johns Hopkins, he had to persevere with his work in the face of a heavy mortality rate in his cases. It was Osler who encouraged him to keep on trying until success came.

Until 1912, when he was appointed to the chair of surgery at Harvard and surgeon-in-chief to the Peter Bent Brigham Hospital, Cushing was laying the foundations on which he built so well in Boston. Physiology and pathology were his favourite studies, but he did not neglect the equally important fields of neurology and ophthalmology. Every new development which could be of use in the study of diseases of the nervous system or employed in the treatment of them was eagerly improved and adapted by him for use in his clinic. With his translation to Boston came the great period of his life; he drew to himself pupils from every civilized country, endowed them with a knowledge of their craft, and engendered in them an affection proof against his ruthless criticism and one which grew with the years. He worked his pupils hard, and after they had set out on their own way, he plied them with questions and tasks which they answered and undertook because it was "the Chief" who had asked them.

Cushing's contributions to surgical knowledge must be his chief claim to fame, but his work on cerebral pathology and physiology is scarcely less outstan ing. His earliest monograph, on the pituitary bod (1912), was the starting-point from which most the present-day work on pituitary physiology ha sprung. He was a first-class clinician who neve neglected or overlooked a sign or symptom which h could not understand. His thoroughness and hi amazing powers of observation, coupled with judgment founded on his own experience, enable him often to arrive at a diagnosis in cases which ha baffled the skill of his colleagues and pupils. H treated the patient as well as the disease, and non better than he knew the value of a word of encourag ment or sympathy to a suffering man or woman.

The War of 1914–18 found Cushing in Franc early in 1915 working with the American ambulanc at Neuilly. Later he worked at No. 46 C.C.S. wit the B.E.F., and towards the end of the War wa transferred to the headquarters of the America Expeditionary Force as its senior consultant i neuro-surgery. He has told the story of those yea in his war diary, written mostly when he was wear after a long day's operating and benumbed with th damp cold of a Flanders winter.

On his retirement in 1932, Cushing left Harvar to return to Yale, there, as he so often expressed i to survey in peace his work on brain tumours and t give to his successors the results of his experienc In his suite of rooms he collected the case records all his patients. These, together with the afte history of each case, provided him with the materi which he used so well in writing his last monograp on the meningiomas. This work was not his onl interest at Yale. Since the early days of his friendship with Osler he had collected books. The histor of his own craft enthralled him and he collecte during the last forty years what must be a uniqu library of early medicine and surgery. When onl a little more than a year ago he came to Grea Britain, libraries and booksellers' shops claimed mos of his time, for he was engaged on a bibliography o his great hero Vesalius, of whose writings an Vesaliana he possessed an unrivalled collection.

In the world of letters, Cushing gained fame b his biography of Osler. Five years of steady readin and writing went into the making of this book, bu during the whole of this time he carried on his wor in hospital and laboratory. It was no mean achievement for a busy man. Others have directed attentio to his self-effacement in this book. That is a tribut to his own sense of modesty, but it removed fro the pages almost every trace of the great friendshi of two great men.

WE regret to announce the following deaths:

Mr. M. A. Bailey, director of the National Institut of Agricultural Botany, Cambridge, on October 16.

Prof. A. Gilligan, professor of geology in the University of Sheffield, during 1922–39, aged sixty-five years

Dr. E. P. Poulton, senior physician to Guy' Hospital and president in 1937 of Section I (Physiology) of the British Association, on October 18, age fifty-six years.

NATURE

SUPPLEMENT

Vol. 144 SATURDAY, OCTOBER 28, 1939 No. 3652

SHORT REVIEWS

ANTHROPOLOGY AND ARCHÆOLOGY

African Women

A Study of the Ibo of Nigeria. By Sylvia Leith-Ross. Pp. 367+8 plates. (London: Faber and Faber, Ltd., 1939.) 15*s*. net.

IT is, of course, no more possible to generalize about the African woman than it is about the women of Europe and still less Asiatic women. Notwithstanding the title of her book, Mrs. Leith-Ross makes no such elementary mistake. She gives her readers the results of a careful and detailed investigation of the position of women among the Ibo people of Nigeria; and even here, she is careful to discriminate. The specific problem with which she was concerned was the reaction of the Ibo woman to the changes which are taking place around her under European administration and owing to the contacts with white civilization. Mrs. Leith-Ross, whose acquaintance with the African is of long standing, directed her observations to female life and character in four different types of community: the isolated bush community, where traditional patterns have suffered little modification, or at least so it would appear; a semi-sophisticated rural community, in which certain ideas and movements are beginning to stir the surface, more especially in the women's societies and organizations, such as on a previous occasion gave rise to serious trouble; a town of some considerable size; and finally the commercial and administrative centre, in which society, both European and more especially African, is cosmopolitan or mixed.

The Ibo woman, like women among many other African peoples, is by no means the conventional down-trodden creature of popular conception. She has a sturdy independence, and in some respects is 'more of a man' than her husband. Nor is she cut to a single pattern. The contrast shown here between the women of the bush and the semi-sophisticated village is instructive, and goes deeper than any difference due to degree of white contact. Apart from such individual differences, however, the progression in change of behaviour and character as the author passes from one type of community to another is very clearly marked.

Manuel de préhistoire générale:

Europe, Asie, Afrique, Amérique. Par Prof. Raymond Furon. (Bibliothèque scientifique.) Pp. 398+8 plates. (Paris: Payot et Cie., 1939.) 50 francs.

DR. FORON'S manual covers a wider field than its title immediately suggests. It deals—as the author recognizes—with what is now termed proto-history as well as pre-history, telling the story of man from his earliest beginnings down to the iron age and the spread of the Celtic-speaking peoples.

As the aim of the author is to provide an introduction to archæological studies, rather than an exhaustive treatise, it would, perhaps, be less than fair to criticize a lack of balance in treatment. Nevertheless, it must be pointed out that while one half of the book is devoted to the descent of man and stone age culture down to the end of the palæolithic, and seventy pages are given to mesolithic and neolithic, one hundred pages have to suffice for the bronze and iron ages; while Australia and America are dealt with apart in twenty pages. As the whole of the Old World is covered by geographical regions throughout, it will be realized that in the later periods Mesopotamia, Egypt, Crete, and the various geographical regions of Europe come in for extremely short measure indeed. Nevertheless, so far as it goes, the matter is as informative as it can be in so brief a space, while the ampler treatment given in the earlier section relating to the physical development of early man and his predecessors, and the account of early stone age cultures, as known in 1937, the date of the latest reference, will be found most helpful as a general introduction. This applies in particular to the lucid account of the bearing of recent geological and palæontological research on the chronological problem in quaternary times.

Tools and the Man

By W. B. Wright. Pp. xvi+236+9 plates. (London: G. Bell and Sons, Ltd., 1939.) 12*s*. 6*d*. net.

IN one sense the late Dr. Wright's presentation and survey of present-day knowledge of the data bearing on early man and the development of his material culture in the early stone age supersede all previous manuals of the kind. It is the first of such handbooks available for the general reader and the student to review critically the earliest material from East Anglia which, it is claimed, shows evidence of human handiwork, and to give an account of the investigations of the Abbé Breuil on the gravels of the Somme and their bearing on and consequences in determining the dating of palæolithic industries, which, it would seem, must now be subjected to considerable revision. A summary account of the latter research by the Abbé Breuil himself for the benefit of British archæologists appears in the current issue of the *Proceedings of the Prehistoric Society*. Further, Dr. Wright, while pointing out that the familiar classification of palæolithic implements, based on the material from France, is too deeply rooted in archæological studies to be ignored in a general survey, adopts and expounds the core-flake classification of implements, entering fully into its technological, classificatory and ethnical implications, as affecting the world-wide study of stone age cultures.

Dr. Wright's critical examination of the evidence and of the development of hitherto accepted theory, consequent upon recent archæological discovery and discussion, gives this manual an authoritative position, and makes it, at present, unique in the English literature.

Studies on the Ice Age in India and Associated Human Cultures

By H. de Terra and T. T. Paterson. (Publication No. 493.) Pp. xi+354+56 plates. (Washington, D.C.: Carnegie Institution, 1939.)

As Dr. de Terra and Mr. Paterson themselves have already summarized the main results of their investigations for the benefit of the readers of NATURE, it would be a work of supererogation to deal here with their report in its final form in detail. It will perhaps suffice to indicate its scope and distribution of topics. The report is in five parts, of which the first deals with the ice age in south-western Kashmir; the second covers conditions in north-west and peninsular India, so far as indicated by investigations in two main regions, the Soan basin and the Indus river; the third section deals with the Nerbada valley Pleistocene; Part iv is concerned with the stratigraphy and typology of Madras; and the fifth and final section is devoted to the late stone age sites of Sukkur and Rohri on the lower Indus, a-proto-neolithic civilization, which it is held may suggest an indigenous evolution and not a foreign origin for Mohenjo-daro and the Indus civilization.

The Mind of Primitive Man

By Franz Boas. Revised edition. Pp. x+285. (New York: The Macmillan Company, 1938.) 12*s.* 6*d.* net.

It is a remarkable tribute to the enduring qualities of the work of the veteran American anthropologist that a new edition of this book should be demanded so many years after its original publication, and when so many developments have supervened in anthropological thought in the interval. The book on its first appearance attained a position of considerable authority not only on account of the originality of its views on the calibre of the mind of primitive man, but also for its statement of the results of the author's observations on changes in the physical characters of immigrants and their descendants after entry into the United States. In the new edition, which has been thoroughly revised, Prof. Boas denounces with unimpaired vigour, in a review of anthropological theories of race, the perversion of racial theory in the interests of political prejudice and propaganda.

(1) Masques Dogons

Par M. Griaule. (Université de Paris: Travaux et Mémoires de l'Institut d'Ethnologie, Tome 33.) Pp. x+896+32 plates. (Paris: Institut d'Ethnologie, 1938.) 275 francs.

(2) Jeux Dogons

Par M. Griaule. (Université de Paris: Travaux et Mémoires de l'Institut d'Ethnologie, Tome 32.) Pp. viii+290+12 plates. (Paris: Institut d'Ethnologie, 1938.) 87.50 francs.

(1) The masked dances which are the ritual manifestation of the ancestor cult of the Dogon of the French Sudan have been made the subject of an elaborate study by M. Griaule. This study is based upon material collected in the course of three expeditions between 1931 and 1937. Although the Dogon all recognize and worship a supreme creating deity, the masks, and the dances in which they figure, and the ancestral cult with which they are associated, take a much more prominent place in their daily life and thought. Of the ancestral spirits, some are regarded as immortal, while others, who belong to the time after death appeared on the earth, are held to be mortal. From the relations to the immortal ancestors, who have returned to exercise a protective function over their descendants, has originated a totemic cult; while the cult of the masks and the dances in which they are used is directed to those of the ancestors who have suffered death.

M. Griaule has made a comprehensive study of an extremely complicated system of religious beliefs, in which *nyama*, a belief akin to the *mana* of Pacific peoples, plays an important part. Students of the history of religions will find here much of the greatest interest.

(2) M. Griaule's record of Dogon children's games, as played in the Bandiagara-Sanga-Kassa district, a region 80 km. long by 10 km. broad, is no less detailed than his study of Dogon masks and dances. It includes a large number of games of every type and variety, some of them belonging to groups which have a very wide geographical distribution. Among the games appearing here which have a special interest are those of a proverbial character, involving a guessing competition, these being especially expressive of Dogon mentality. The author notes a large number of string figures, which have been both carefully recorded and fully illustrated. M. Griaule's monograph is a valuable and very instructive contribution to the literature of a fascinating study.

BIOLOGY

Intermediate Botany

By L. J. F. Brimble. Second edition. Pp. viii + 562. (London: Macmillan and Co., Ltd., 1939.) 8*s*. 6*d*.

THAT in a comparatively short time a second edition of "Intermediate Botany" should be called for is clear evidence that it has been appreciated by teachers and students and has been found as helpful to them as we expected when it first appeared.

While the subject-matter has not been materially altered, the text has been revised and brought up to date in certain directions. Thus in connexion with the discussion of the acceleration of germination a paragraph has been added pointing out the agricultural and economic importance of the recent researches of the Russian investigator Lysenko. By subjecting the germinating grain of winter wheat to low temperature he was able to get it to reach maturity even when sown in spring. This yarovization of grain, as it has been called, is one of the most important botanical discoveries of recent years and its implications will probably have far-reaching results.

In describing the interesting experiments dealing with growth-promoting substances or hormones Mr. Brimble has extended his account by directing attention to the horticultural importance of recent work on this subject, which aims at accelerating the formation of roots on cuttings by treating the latter with synthetic auxins and hetero-auxin. A figure showing the effect of these substances on the formation of roots on cuttings of Buddleia (not Buddleja) is given.

This and other new figures which have been added increase the attractiveness of the book and will be found helpful by its readers. In some cases also better illustrations take the place of some appearing in the first edition. Thus the photograph of the roadway through the base of the Big Tree (Sequoia) and the figure of the Venus fly trap are distinct improvements.

Speaking generally, the value of the book has been enhanced by the careful revision and by the additions made to the text and the illustrations. The second edition will receive as cordial a reception as the first has done.

Practical Botany

A First Year Course for University and Intermediate Science Students. By Dr. S. Williams and Dr. G. Bond. Pp. 96. (London: Edward Arnold and Co., 1939.) 5*s*. 6*d*. net.

THIS book follows the method now very popular in the United States for practical laboratory guides whereby the pages are loose; this, as the authors state, allows "for the interleaving of the book with drawing paper and thus the students' drawings should make the completed book a reasonably adequate factual text-book". The authors omit, however, to point out another important advantage of the method they have adopted, that is, the opportunity thus afforded of changing the order of things in conformity with varying laboratory routine.

The authors have wisely kept the number of illustrations down to the absolute minimum—eight figures in all.

The standard of the course is indicated in the title; but the course is very full, thus allowing a certain amount of choice, and accuracy and personal observation and experimentation are obviously the keynotes throughout.

Unlike many science text-books of this standard, this contribution will certainly fill a serious gap, for, so far as we know, there is no satisfactory practical guide to botany of the standard of post-School Certificate and post-Matriculation. It can be recommended to university departments of botany for the use of first-year students, and to schools where botany is taken in the Higher School Certificate examinations.

Vitamine und Hormone:

und ihre technische Darstellung. Von Dr. Hellmut Bredereck und Dr. Robert Mittag. Teil 1: Ergebnisse der Vitamin- und Hormonforschung. (Chemie und Technik der Gegenwart, herausgegeben von Dr. H. Carlsohn, Band 15.) Zweite neubearbeitete Auflage. Pp. xii + 138. 7 gold marks. (Leipzig: S. Hirzel, 1938.)

Vitamine und Hormone und ihre technische Darstellung

Teil 2: Darstellung von Vitaminpräparaten. Von Dr. Franz Seitz. (Chemie und Technik der Gegenwart, herausgegeben von Prof. Dr. H. Carlsohn, Band 20.) Pp. xi + 205. (Leipzig: S. Hirzel, 1939.) 10 gold marks.

THESE are two indispensable volumes for all who have to follow closely the progress of work in the fields of vitamin and hormone chemistry. They are skilfully prepared encyclopædias giving an immense amount of information in an unusually small compass. Particularly valuable is Dr. Franz Seitz's volume dealing with the technical aspects of the subject. A bibliography of technical and patent literature is given which is alone worth the cost. Two admirable works in a well-planned and well-executed series of monographs. J. C. D.

The Insect Legion

By Dr. Malcolm Burr. Pp. xiv + 321 + 16 plates. (London: James Nisbet and Co., Ltd.. 1939.) 12*s*. 6*d*. net.

MANY popular books on insect life have appeared in the English language but the present volume, from the pen of a mining engineer, is undoubtedly the best of them. Since Dr. Burr is also himself an original investigator of insect life, besides being a traveller and a linguist, he is able to approach his subject from the widest point of view. The result of his efforts is a book of real charm: it is moreover reliable and accurate as to its facts and details, and its author has widely combed the revelant literature for much of his information. We can unreservedly recommend it as an admirable introduction to its subject and one that will appeal to adults and juveniles alike.

CHEMISTRY

(1) Dyeing with Coal-Tar Dyestuffs

The Principles Involved and the Methods Employed. By C. M. Whittaker and C. C. Wilcock. Third edition. Pp. vii+326. (London: Baillière, Tindall and Cox, 1939.) 12*s*. 6*d*.

(2) Hair-Dyes and Hair-Dyeing Chemistry and Technique

By H. Stanley Redgrove and the late Gilbert A. Foan. A new edition completely revised by H. Stanley Redgrove and J. Bari-Woollss. Pp. xiv+214+8 plates. (London: William Heinemann (Medical Books), Ltd., 1939.) 10*s*. 6*d*. net.

THESE two books on dyes and dyeing are in such striking contrast to one another as to justify their inclusion in the same notice.

(1) The first is a succinct account of the general processes of dyeing with the so-called coal tar dyestuffs—a term better indeed than 'aniline' dyestuffs, but nevertheless redundant since there are nowadays no dyestuffs of importance that are not derived from coal tar intermediates.

The book is divided into fifteen sections each dealing with some group of dyestuffs and giving information of value to the users of dyes. Section xi on the dyeing of rayons, and Section xii on the dyeing of synthetic fibres with an affinity for wool dyestuffs, are particularly well written. The book will be of interest to all concerned with the subject of dyeing.

(2) The second is a most amazing book which will be found of great interest to a wide circle of readers. To the uninitiated it is a revelation by which one can recognize a host of friends. The dreadful devices to which the female of the species subjects herself in order, in her opinion, to make herself pleasing to the male, are set out here in all their terrible entirety. The illustrations alone give one a glimpse into the beauty parlour which must make every male shudder with horror. But so be it! Women have done it since the beginning and will do it to the end. J. F. T.

Inorganic Chemistry

By F. A. Philbrick. Pp. viii+396. (London: G. Bell and Sons, Ltd., 1939.) 6*s*.

THIS book provides a course in inorganic chemistry up to the standard of the Higher Certificate, Inter B.Sc. and First M.B. examinations. The author has wisely devoted the introductory chapters to a brief sketch of chemical principles such as the atomic and molecular theories, electrolytic dissociation and electronic theory of valency, which should prove of value to students who have little knowledge of physical chemistry.

The elements are classified and discussed in the order in which they occur in the Mendeléeff table; for example, copper and silver are described in the same chapter as the alkali metals, and manganese, a steel-forming metal, finds its way into the end of the chapter on the halogens. This old-fashioned and clumsy arrangement is not in keeping with the modern and up-to-date factual matter which is given in the text, and is partly responsible for the too brief inter-comparison of the elements. The omission, however, of detailed descriptions of unimportant compounds is a welcome feature, as is also the emphasis which has been laid on the practical applications of inorganic chemistry. The numerous photographic illustrations, collected from many different countries, are an additional attraction. Questions are given at the ends of the chapters, and a selection of revision papers is provided at the end of the book, together with answers to the numerical problems. The omission of logarithm tables is to be regretted, and the index is certainly too brief for a work of this calibre.

Apart from these criticisms, the book is a welcome addition to existing text-books of intermediate standard, and can be recommended to both teachers and students of chemistry. A. C. C.

Intermediate Chemical Calculations

By Prof. J. R. Partington and Kathleen Stratton. Pp. x+240. (London: Macmillan and Co., Ltd., 1939.) 6*s*. 6*d*.

IN accordance with its title, this book provides a complete course of numerical examples, intermediate in standard between the General School Certificate and B.Sc. examinations. A concise but clear account of the fundamental principles underlying the calculations is given at the beginning of each chapter or section, and then suitable examples are worked out in detail for the guidance of the student before he tackles the numerous problems. The latter are chosen in part from former Higher Certificate, M.B. and University Scholarship examinations, and answers are provided at the end of the book.

The subject-matter throughout is accurate and up to date; for example, problems are not set which imply that the extent of ionization of a strong electrolyte can be obtained from molecular weights in solution or from conductivities. It is gratifying, too, to find a clear distinction between the density and relative density of a gas. In the opinion of the reviewer, a copy of this book should be possessed by all teachers and university students, and should be available for the 'Science Sixths' of all schools.

A. C. C.

Wood Pulp

By Dr. Julius Grant. Pp. xi+209. (Leiden: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1938.) 7 guilders; 15*s*.

THIS is one of the "New Series of Plant Science Books" edited by Dr. Frans Verdoorn and printed and published in Holland. It is a comprehensive treatise and contains everything worth knowing on the subject of wood pulp. The multitude of uses to which this material is now put makes it at the present day one of the most valuable natural products that exist. Although the supply is enormous, especially in our jungles and forests, the cost of collection must be almost prohibitive except in places that are supplied with water-transport or other such facilities. Those who have been so fortunate as to visit Shawinigan will realize the speed with which forests in vourable positions are disappearing. The work of forestation lingers, alas ! far behind.

The book contains a very readable account of the lphite process, with a section devoted to the history this great discovery. The other chief processes of rification are also described, and those who are terested will find all the information they need. he book is well set up and is likely to be of great rvice to those concerned. J. F. T.

ENGINEERING

lectro-Acoustics

y Prof. Dr. Erwin Meyer. Pp. xi+117+12 plates. ondon: G. Bell and Sons, Ltd., 1939.) 10*s*. net.

BOTH the orthodox student of electricity and the orthodox student of acoustics are at a loss when nfronted with the intricate and subtle marriage tween the two classical subjects which has taken ace in recent years in response to public demand. Dr. E. Meyer, from the erstwhile Heinrich Hertz stitute, now known as the Institut für Schwingungsrschung, came, at the invitation of the University London, and gave a series of five lectures at the stitution of Electrical Engineers on his view of e present position of electro-acoustics ; the present lume records his material, showing that he disarged his task well. He speaks of what he s first-hand knowledge, and his almost entirely eutonic set of references shows that the Americans e not undisputedly in the lead in this field. The apters, corresponding to the lectures, deal with ysical and physiological foundations, which clude evidence that the strike note of a bell does t exist, and some new applications of supersonic ves ; electro-acoustical measurements, describing acoustic grating analyser, and the high-speed vel-indicator and the spectral analyser in use at e National Physical Laboratory ; microphones and ud-speakers, with reference to response-curves and ansient times, and the logarithmic modulation eter ; sound recording and electrical music, with me explanation of magnetic recording and note nthesis ; and architectural acoustics, in which ethods and results of reverberation measurements d the absorption of acoustic materials are considered. th an engaging reference to his scheme of measuring verberation periods with audience, by using isolated ords from a full orchestra and suitable filters. early Dr. Meyer could deal with few details, but e ground covered is impressive and gives a plan r those who are engaged in working in a small rner of it. L. E. C. H.

ndbook of Technical Instruction for Wireless legraphists

H. M. Dowsett. Sixth edition. Pp. xx+624. ondon: Iliffe and Sons, Ltd., 1939.) 21*s*. net.

HE present text is obviously of little use to the scientifically minded, but it serves two sential purposes very well. It shows clearly the pe of apparatus which the practical wireless man s to deal with, and its mode of operation, information which is of the greatest importance to researchers and developers of new types of equipment. At the same time, it forms an excellent record of the state of the art of radio communication at the moment, omitting only high-powered point-to-point working. The aim is to assist operators to get their certificates, and to acquaint them with every conceivable type of apparatus they are likely to come across, for communication, navigation, and for emergency. The circuit diagrams are particularly clear, and much information is tabulated for easy reference.

L. E. C. H.

MATHEMATICS

The Kelley Statistical Tables

By Prof. Truman Lee Kelley. Pp. vi+136. (New York: The Macmillan Co., 1938.) 20*s*. net.

THE normal or Gaussian distribution occupies a central position in statistical theory and practice, and is therefore naturally the most completely tabled distribution function. Prof. Kelley now takes a further step, and provides a table of the abscissæ and ordinates of the distribution to 8 decimal places against the cumulative probability as argument, proceeding by intervals of 0·0001. The table is clearly printed and of a convenient size, and the minimum of interpolation is required to provide results to the accuracy ever likely to be demanded in statistical problems.

Prof. Kelley takes the opportunity of including in the volume other useful tables. For values of p proceeding by intervals of 0·0001 from zero to unity he gives to 8 decimal places values of $\sqrt{pq}$, $\sqrt{1-p^2}$, and $\sqrt{1-q^2}$, where q is $(1-p)$. Statisticians will recognize these quantities as being of frequent occurrence in relation to the binomial distribution and the theory of correlation. Another table gives the coefficients of the cubic Lagrangian interpolation formula to 10 decimal places for an argument proceeding by intervals of 0·001. With modern calculating machines these coefficients are often more convenient than the Everett coefficients used in connexion with a difference formula.

Statisticians will appreciate the labours which have gone towards this well-produced volume.

The Theory and Use of the Complex Variable

An Introduction. By S. L. Green. Pp. viii+136. (London: Sir Isaac Pitman and Sons, Ltd., 1939.) 10*s*. 6*d*. net.

THE theory of functions of a complex variable is usually presented in exhaustive treatises, demanding high mathematical attainments from their readers. Yet engineers and others who have neither the time nor the specialized training in pure mathematics to master such treatises find that they require some of the leading ideas of the subject. Mr. Green provides an introductory account of the complex variable and of conformal representation in a very simple and compact form, demanding from the reader little more than elementary calculus and co-ordinate geometry, with some indication of applications to problems of mathematical physics, aeronautics and electrical engineering.

Miscellany

Borneo Jungle

An Account of the Oxford Expedition to Sarawak. By John Ford, C. M. Hartley, Tom Harrisson, Patrick M. Synge, Edward Shackleton. Edited by Tom Harrisson. Pp. x+254+32 plates. (London: Lindsay Drummond, Ltd., 1938.) 15*s*. net.

"BORNEO JUNGLE", which describes an expedition of the Oxford University Exploration Club to Sarawak in 1932–33, stands out in the class of travel books in virtue of its method of composition. Instead of one or two authors, it has five, each contributing a chapter. The result is both entertaining and instructive.

The organizer of the expedition, Mr. Harrisson, who notwithstanding his not very advanced years—the average age of the members of the expedition was then twenty years—has already won a reputation as a writer of original views, describes the organization and outlines the work of the expedition as a whole. The chapters by his colleagues all contribute some interesting observations of the daily life and character of the jungle folk of Sarawak; but without being invidious, special mention may be made of Mr. Patrick M. Synge's account of collecting epiphytes in the forest at different altitudes and his discussion of the relation, if any, of the æsthetic qualities of the flora to the art motifs of the people.

Members of the expedition and others working on the material collected have already produced twenty-nine scientific papers, while further studies are in course of preparation. The standing of the expedition, in a scientific sense, is therefore assured. It is necessary to say this, as Mr. Harrisson vigorously attacks scientific exploring expeditions in general, especially if their aim is the collection of specimens, and expeditions of the type of those organized by the Oxford Exploring Club more particularly as failing in their educational aim. This raises too large a question for discussion in a brief notice; but in part the author supplies an answer in recognizing the constraining influence of finance.

The Climate of Madeira

With a Comparative Study. By Vice-Admiral Hugo C. de Lacerda Castelo Branco. Translated from the French by Dr. Alberto Figueira Jardim. Pp. 118+9 plates. (Madeira: Delegação do Turismo da Madeira, 1938.)

THE little book by Vice-Admiral H. C. de Lacerda Castelo Branco on the climate of Madeira, or more precisely Funchal, an English translation of which is under notice, was written with the definite object of comparing the merits of the island with those of other favoured resorts, and it certainly contains a considerable amount of propaganda. Nevertheless the author, who was many years ago director of the meteorological observatory at Lourenço Marques, has been at pains to embody in it much scientific data and to direct attention to the need for further investigations. Some thirty earlier publications, dating from 1811 onwards, are commented on briefly as a preface to his own 'sketch' based upon observations at Funchal since 1923 and official averages for 1916–35. Both sets of figur show the well-known characteristics of mild winte and moderately warm summers. From a table p. 47, relating to the years 1923–32, the absolu maximum temperature in July (82·6° F.) appea lower than that in any of the other months fro April to October. It may be noted in passing th this is doubtless due to the shortness of the period. considerably higher values have been recorded in Jul

In the comparisons with other climates the auth seems over-lavish in his praise of the relative val of that of Funchal, but he is careful to state th conditions in other parts of the island may be le good. Further research is advocated not only regards the climate but also into certain medical a other matters affecting the general conditions of li there which are discussed in the concluding chapter

L. D. S.

Mineral Tables

For the Determination of Minerals by their Physic Properties. By Arthur S. Eakle. Third editio revised by Prof. Adolf Pabst. Pp. v+73. (Ne York: John Wiley and Sons, Inc.; London: Cha man and Hall, Ltd., 1938.) 7*s*. 6*d*. net.

PROF. A. S. EAKLE, of the University of Ca fornia, published tables in 1904 by which th common minerals could be 'run down' by using in systematic manner the properties of streak and colou and by the observation of other characters such hardness, crystal symmetry, cleavage and fractu the habit or structure of the mineral, the speci gravity, and the chemical composition. Dr. A. Pab has revised Eakle's tables, making such additio and changes as were necessary to bring them up date. About 200 minerals are included. For t application of the tables the only apparatus requir is a streak-testing plate of unglazed porcelain, pocket knife and set of minerals for the scale hardness, a magnet and a pocket lens. Admitted tests with this simple equipment do not suffice identify definitely every mineral, and recourse mu frequently be had to determination of speci gravities and to optical and chemical tests, but t application of the physical tests in a systematic w is good training for the student who will need identify minerals in the field.

The League of Nations and the Rule of Law, 1918–19

By Sir Alfred Zimmern. Second edition, revise Pp. xiii+542. (London: Macmillan and Co., Lt 1939.) 12*s*. 6*d*. net.

THE second edition of this book differs but lit from the first edition of 1935. It has not be extended beyond the limits then planned and althou it has been thoroughly revised and the references the literature brought up to date, new matter h been incorporated chiefly in the chapters on t drafting of the Covenant, and the history of t League of Nations, the latter merely bringing t account of the Abyssinian dispute up to 1936. No the less the book remains an invaluable guide to t problems involved in the re-establishment of the r of law between nations.

PHYSICS

igher School Certificate Practical Physics

E. Armitage. Pp. xx + 239. (London: John urray. 1939.) 6*s*.

THE author's aim in this book is two-fold: first, to enable a form of post-School Certificate pupils commence different experiments without wasting ne at the beginning of a practical period, and condly to cover the experiments that are likely to met in the various practical examinations for igher Certificate, Inter-B.Sc., and First M.B. aminations. The book includes more than a mdred experiments in all the necessary branches, d so a very useful selection can be made.

One outstanding feature of the book is the attempt ade by the author to have the complete account each experiment in front of the student while orking, thus obviating the necessity of having to rn pages over. This undoubtedly has its advantages, it it rather detracts from the appearance of the ok, inasmuch as some pages are of necessity left lf blank.

There are many diagrams in illustration of the paratus used, but these might in many cases have en larger and bolder.

The treatment of the experiments is very sound, d a pleasing feature is the attention paid to the pression of results graphically—a point which serves due emphasis—though the article on graphs the early part of the book seems scarcely necessary a book of Higher Certificate standard. Indeed ere are several instances of superfluous instructions d so on, since it must be assumed that most of the udents will have already gone through a course the handling of apparatus.

From a utilitarian point of view, the book is doubtedly a distinctly helpful one for those udents who wish to become accustomed to the type experiment they are likely to encounter in their actical examinations; it will, however, scarcely tisfy the needs of those who believe in learning a t of the theory of the subject through the practical proach, a method not to be despised even with igher Certificate students.

A useful addition to the book would be tables physical constants, also a set of mathematical bles.

actical Physics

y W. F. F. Shearcroft and J. H. Avery. Pp. xvi + 8. (London: William Heinemann, Ltd., 1939.) . 6*d*.

THIS book claims to provide for any course immediately following School Certificate or atriculation, and to cover Higher School Certificate quirements up to distinction standard. There is a rge selection of experiments—151 in all—though appreciable number of these experiments would rmally be dealt with in a School Certificate urse.

A good deal of time has evidently been spent in anning the treatment of the experiments, and one good feature which will undoubtedly appeal to students is the numbered instructions describing precisely how the experiment should be carried out.

Seventeen pages at the beginning of the book are devoted to introductory matter and experimental instructions, but one feels that quite a lot of this could be omitted from a book of this standard. In the electricity section, about nine pages are devoted to an explanation and diagrams of elementary apparatus, but surely this should scarcely be necessary. In view of the importance attached to diagrams by examining bodies, it would have been a better example to students to have used the space so taken up in the book to make larger and bolder diagrams of the apparatus, etc., used in the experiments, and to include diagrams where they are at present missing.

Due attention is very rightly paid to graphical work, and it is pleasing to see that in the experiments on light the 'optical bench' treatment, using actual beams of light, at least holds its own with the 'pin' or 'no-parallax' method.

A useful set of exercises is included at the end of the book, also two sets of tables, but one feels that this section could with advantage have been larger; mathematical tables in particular would be very useful to students. Finally, certain illustrations arranged vertically along the edge of the page are irritating, while the plate facing p. 204 would seem to be totally unnecessary.

Introductory Quantum Mechanics

By Prof. Vladimir Rojansky. Pp. x + 544. (New York: Prentice-Hall, Inc.; London, Glasgow and Bombay: Blackie and Son, Ltd., 1939.) 5.50 dollars; 22*s*. 6*d*. net.

THE main difficulty which a text-book on quantum mechanics has to overcome, namely, to present the maximum of physical results with the minimum of mathematical formalism, is very well overcome in this book, by clever navigation between the Scylla of rigour and the Charybdis of obscurity.

The operator calculus, the theory of eigenfunctions and eigenvalues, the matrix method are well explained and illustrated by significant examples. Each chapter is provided with a collection of exercises which will be very useful for students as well as for teachers. The development of the physical notions does not follow the historical order. Schrödinger's method is introduced first and its fundamental assumptions are stated somewhat axiomatically. Heisenberg's and Dirac's considerations are described in later chapters.

The advantage of this procedure is its brevity, and the possibility of a logically coherent system, connecting all different aspects of the theory. This purpose has been achieved; the presentation of the fundamental statistical conceptions especially is very satisfactory. But a student who would learn quantum mechanics from this book only will get no impression of the intellectual struggle which led to the final theory. This unhistoric attitude is observable even in such details as the quotation of literature; the names of American authors who have added refinement to an existing theory are included, while those of the originators are omitted. Apart from these minor objections, the book can be warmly recommended.

Elementary Survey of Physics

A Non-Mathematical Presentation, with a Special Supplement for Pre-Medical Students. By Prof. Arthur E. Haas, with the collaboration of Prof. Ira M. Freeman. Pp. x+204. (London: Constable and Co., Ltd., 1939.) 7*s.* 6*d.* net.

THERE is a tendency to-day to impart a general acquaintance with physical science to students outside this field; even those in the college of liberal arts are now taught the elements of physical science as part of their general culture. A serious difficulty arises from the antipathy on the part of most students, including pre-medical students, to the application of mathematical methods. Prof. Haas has presented a survey of physics without introducing mathematics except of the most elementary nature. In spite of the absence of mathematics, the field covered is comprehensive, and the explanations are so lucid that no one need be deterred by the fear of failure to understand the physical picture of Nature delineated by the author.

There are two appendixes. The first deals with the more important applications of physics to medicine, especially in such fields as light therapy, electrotherapy, radium therapy, etc. The second appendix supplies a number of elementary formulæ which can be applied by anyone with only a very meagre mathematical equipment. It may be safely predicted that the work will commend itself to a large number of students, and the general public too will find it most readable.
M. D.

PSYCHOLOGY

Introduction to Psychology

By Edwin Garriques Boring, Herbert Sidney Langfeld, Harry Porter Weld and Collaborators. Pp. xxii+652. (London: Chapman and Hall, Ltd.; New York: John Wiley and Sons, Ltd., 1939.) 15*s.* net.

IT has been generally felt for many years that the writing of an up-to-date text-book on psychology required specialized knowledge of so many branches of the subject that it was beyond the power of any one man. Two or three years ago, three distinguished American psychologists, with the help of a number of collaborators, produced "Psychology: a Factual Textbook", which was very generally welcomed as a satisfactory text-book for courses in Great Britain also. As a result of the numerous suggestions they received from users of the book, they have now produced a new edition so radically different that they have given it a new title.

Their earlier edition followed the conventional order of treatment in which sensation and perception came first and led up to problems of personality and social psychology at the end. They have now ma the bold innovation of reversing this order. Th have felt that much of the treatment of sensati and perception, about which relatively much is know can with advantage be left to specialist courses. Al they have thought it an advantage to start with t functioning of the organism in the social environme about which the student has more previous knowled than he has of sensory functions. This is no dou true, but this method of approach sacrifices the a vantage of beginning with a part of the subje on which there is much exact scientific knowled

The previous edition proved itself a satisfacto text-book. It was up to date, accurate and eclecti In its new form, with additional matter and increased number of collaborators, it appears to ha sacrificed none of these merits. It should prove to as satisfactory as its predecessor. Whether the ne order of presentation is the better can only be to by trial.
R. H. THOULESS.

Children with Delayed or Defective Speech

Motor-Kinesthetic Factors in their Training. I Sara M. Stinchfield and Edna Hill Young. P xvi+174. (Stanford University, Calif.: Stanfo University Press; London: Oxford Universi Press, 1938.) 14*s.* net.

THIS most useful book describes the theory a practice of the Hill Young School of Speech Los Angeles. It is divided into two parts, the fi by Dr. Stinchfield, discussing the problem to solved in dealing with children with delayed defective speech, and the second by Mrs. Youn dealing with the practical side.

It is estimated that there are four million childr in the United States handicapped in the use of speec

The treatment consists briefly in training muscul action for whole words. There is a liberal supply photographs showing how the child is taught to u his muscles in the enunciation of the various wor used.

Man against Himself

By Karl A. Menninger. Pp. xii+485. (Londo Bombay and Sydney: George G. Harrap and C Ltd., 1938.) 15*s.* net.

DR. K. A. MENNINGER, who some years a produced an excellent book, "The Hum Mind", has given us a very interesting book on so of the wider implications of suicide in "Man agai Himself".

The book is largely based on psycho-analyti principles. After a brief consideration of suicide commonly understood, the author deals with wh he calls chronic suicide, which includes asceticis neurotic invalidism and alcoholic addiction, a then with focal suicide, which includes mutilatio purposive accidents, impotence and frigidity a polysurgery.

The treatment consists in self-reconstructi dealing with the aggressive, self-punitive and ero motivations.

NEWS AND VIEWS

Ministry of Information

Question time in the House of Commons during the past few days has produced a crop of inquiries about the Ministry of Information. As is well known, the staff of the Ministry has suffered drastic reduction as the result of the criticism levelled against it. On October 18, Sir John Graham Kerr asked the Parliamentary Secretary to the Ministry of Information, "in view of the important part played in modern warfare by science and in view of the importance of accuracy in public information regarding such matters, how many of the 190 members of the staff of the Ministry, of which particulars have recently made public, are university graduates in science ?" Sir Edward Grigg said in reply that the "information is not available and could only be obtained at an expense of time of which I should not feel justified in giving to the inquiry". He added that "scientific advice can be obtained whenever necessary from a large range of experts in Government service and outside it, and that it is therefore unnecessary to add on that account to the establishment costs of the Ministry". While it will not be denied that such advice is available, it is difficult to see how the Ministry, without scientific guidance from within, can hope to utilize to the full the scientific knowledge of the country.

Camouflage (Advisory Committee)

On August 2 last, an advisory committee on camouflage by the use of paint, was appointed by the Government, which agreed that it should include a scientific member. Sir John Graham Kerr asked the Home Secretary on October 19 how many meetings this committee had held since its formation. Sir John Anderson, in reply, stated that the first meeting of the committee was held on October 18. In reply to a supplementary question, Sir John Anderson said that "the committee has been so constituted as to bring to bear on this important question of camouflage the opinions of many people who hold differing views on the theoretical and practical aspects of the question. The reference to the committee is very wide, and I have no doubt that the committee will be in a position to address itself to the question". No explanation was offered of the lengthy delay between the setting up of this committee and its first meeting.

Advisory Research Council of the Chemical Society

The Council of the Chemical Society has formed an Advisory Research Council, under the chairmanship of Sir Robert Robinson, the main function of which will be, when approached, to bring to the notice of fellows and others engaged in chemical research, subjects for investigation likely to be of potential value to the nation at the present time. In the first instance such advice will be made available to unremunerated research workers (that is, unremunerated as research workers for some specific purpose) in universities, colleges and other research institutions, and to research students in receipt of grants not definitely related to any particular topic or in regard to which the topic can be changed. It is hoped to effect liaison with Government departments and industrial organizations so that the Advisory Research Council may be cognizant of pressing problems needing investigation and thus be able to suggest lines of research of national value. It will not be a function of the Council to exercise control over any research that may be undertaken. The field to be covered will embrace every branch of pure chemistry and include biochemistry and metallurgy. Chemists and various organizations (industrial and otherwise) will be invited to send in suggestions for research, and a list of topics for research considered of national importance will be drawn up and will normally be available to those wishing to make use of it for the purpose of initiating an investigation. Inquiries and suggestions may be sent to the General Secretary, Chemical Society, Burlington House, Piccadilly, London, W.1.

New Anthropological Periodical in India

India is so poorly supplied with anthropological literature that the appearance of a new periodical to be devoted entirely to the scientific study of anthropology must be regarded as something of an event. The work of the Indian Anthropological Institute, to which reference is made elsewhere in this issue of Nature (see p. 721), has been hampered seriously ever since its inception in 1936 through lack of an official organ for recording the deliberations and discussions of its members. Financial conditions proved an insuperable obstacle until the University of Calcutta, thanks to the good offices of the Vice-Chancellor, Mr. Syamaprasad Mookerjee, generously came to its assistance with an offer to assume responsibility for printing the *Journal* of the Institute free of charge. The first issue, which has appeared recently, includes communications received from members up to the close of 1938, among them the presidential address by Dr. J. H. Hutton, the first president, in which he puts forward the suggestion that the Institute should formulate a five years' plan of research, to be entrusted to sub-committees, and Colonel Gordon offers some pregnant, as well as pungently critical, comments on the methods and organization of archæological studies in India. Reference to both these communications will be found on another page. A cognate question is raised by Colonel Germano da Silva Correia, who after a critical examination of the various theories of the racial origins of the peoples of India, put forward by anthropologists from the days of H. H. Risley onward, suggests that the methods of inquiry hitherto pursued should be supplemented by a systematic survey of blood groups. Among other contributors Mr. Sasanka Sarkar puts forward a proposal for a classification of the nasal elevation index, and Dr. Biren Bonnerjea, profiting by his sojourn in the United States, discusses "Fish-Hooks in North America and their Distribution". We offer the new periodical a cordial welcome, and wish it a long and prosperous career.

Extension of Electric Power Supplies in U.S.S.R.

ACCORDING to "Russia Today" Press Service, the Commissariat of Power Stations of the U.S.S.R. is expending a sum of 1,056 million roubles on this purpose in the present year, when 882,000 kw. will be added to the capacity of the generating plants of the Union. The capacity of the power stations in the Ukraine has been augmented considerably, a notable addition being a 100,000 kw. turbine to the Zuyev Station, which is one of the largest in the U.S.S.R. Two large turbines have been added to the Moscow power system and three new heat and power stations are in course of construction in that city. The power system of the Urals has been augmented by a 50,000 kw. generator at the Central Urals Station near Sverdlovsk, which brings the capacity of this station up to 150,000 kw. A heat and power plant was recently put into operation at the Kamensk Aluminium Works in the Urals. Work on a large scale is also proceeding on hydro-electric power plants. This includes work on the world's largest power project, the Kuibyshev Hydro-Electric Centre (on the Samara Bend of the Volga), the power plant of which when completed will have a generating capacity of 3·4 million kw., and the hydro-electric power stations at Uglich and Rybinsk, two further links in the chain of the Greater Volga Project. The Uglich and Rybinsk stations will have a combined capacity of 440,000 kw. Construction is in progress on the first underground hydro-electric power station beyond the Arctic Circle, in the district of Kandalaksha, in the Murmansk Province. This station, which will have a capacity of 150,000 kw., will be the third power plant in the Soviet Far North. To provide power for the growing non-ferrous metal industry in the Altai Mountains, building has commenced for a generating station of 240,000 kw. capacity on the River Irtysh in Kazakhstan.

Precautions against Flooding in the London Tubes

IN order to protect railway and road transport services from the risks arising from air raids, London Transport, in conjunction with the Ministry of Transport, has undertaken a great programme of emergency work. The *Electrical Times* of October 19 states that the total cost of the programme, including that already completed at the outbreak of the War, will be about a million pounds. The most difficult part of the problem was how to protect the underground railways from flooding either from the Thames itself or from sewers or water mains where these are in close proximity to stations. There has been already a preliminary inspection of two examples of such protective works, namely, floodgates installed at Waterloo, where the tunnels of the Northern line go under the river, and work which has been done at King's Cross Underground, to guard against flooding from water mains and sewers. When the works are finished, all the stations and sections of line at present closed will be reopened and journeys on the Underground will be as safe as in peace time.

BOTH the floodgates installed at Waterloo and Charing Cross stations on the Bakerloo line are electrically operated. They enable the sub-fluvial sections of the lines between these stations to be isolated during an air raid and so the risk of damaging the under-river tunnels is avoided. Similar floodgates are being installed at Waterloo and Strand stations on the Northern line, which also runs under the Thames. Each gate is made of built-up steel of an overall thickness of thirteen inches and weighs very nearly six tons. In normal open position it is against the headwall of the station platform tunnel, against the tunnel mouth. It is made to slide horizontally into position across the tunnel mouth within a framework of cast iron and can be operated either electrically or by hand. For electrical operation control is by push-button. The gates would resist a force of more than 800 tons, which is several times greater than any possible pressure of water that might have to be borne. The gates on the Bakerloo line were actually closed during each of the three air raid warnings which marked the ourbreak of war, the time taken to close them being less than three minutes. The gates were designed by W. T. Halcrow, consulting engineer, in conjunction with London Transport's engineers.

Commercial Irradiation of Food

IT is now sixty years ago since it was first discovered that bacteria are killed by exposure to sunlight, and that the bactericidal effect is due to rays of short wave-length. For medical purposes the use of such ultra-violet rays is now well known, but it is not generally known to what extent irradiation is used commercially in the preparation of foodstuffs, and the engineering devices that are employed for obtaining the ultra-violet rays. Until recently, sterilization of water by ultra-violet radiation has been hampered by the complexity of the equipment available (*Elect. Rev.*, Sept. 23). Recently, Messrs. Hanovia, Ltd., have brought out the new 'Uster' type of sterilizer, which uses a simple straight generating quartz mercury arc tube with a 700-watt loading. This starts automatically by an electronic discharge from activated metal electrodes. One of these units can deal with 600 gallons of fluid per hour. Mr. Harding, a director of E. Harding and Sons, Birmingham, states that in a bakery he finds that dough which has been subjected to ultra-violet rays during the seven to ten minutes it is mixing not only gives a loaf a better colour, owing to the slight bleaching action of the rays, but also causes a definite improvement in fermentation. Another application of ultra-violet radiation is to determine quality or age by fluorescent effects. Many substances absorb ultra-violet rays and re-emit them as visible light of certain colours. The colours are specific and characteristic for each substance, but minute differences in chemical composition often cause large differences in the colours of the emitted light. An egg, for example, changes its colour from mauve-red when it is newly laid to pale blue as it grows older, and a mixture of margarine and butter appears an unmistakably different colour from pure butter.

A Geothermic Generating Plant

Italy has not confined its attention to developing hydro-electric power. At Bastardo in Umbria, Italian lignite is used to supply a large electric power station. In addition, there has recently been exploitation of the natural steam resources of the borax mines geysers in Tuscany. The Larderello geothermic electric station is the best known. Antonio Giordano, in an article published in the *Electrical Times* of October 19, gives an account of its growth from 1905 to the present time. Its capacity initially was 16,000 kilowatts. In the past twelve months, in association with the electrification of the Viareggio–Rome section of the Turin–Naples railway, running along the western Italian coasts, a new geothermic generating plant of 50,000 kw. capacity has been built. Its operation in the first few months has been so successful that the Borax Company of Larderello has placed orders for two new 12,000 kw. machines, for the necessary heat transformers, etc., and for the construction of a completely new power station at Castelnuovo, which will house five generating sets each of 12,000 kw. When the new developments are completed, the aggregate capacity of geothermic generating plants in Italy will amount to 135,000 kw., and the possibilities of further extensions are not exhausted. A problem connected with the exploitation of natural steam for power generation purposes is its purification. The difficulty was solved successfully by Prince Ginori Conti, chairman of the Larderello Company, by means of specially designed evaporator units. These consist of primary pipes through which the natural steam is circulated at a pressure of 3 kgm. per sq. cm., the pipes being immersed in water in a cylindrical tank. The energy is generated in the turbo-alternators at 25,000 volts and transmitted to the substations along the Viareggio–Rome railway, where it is converted to 3,000 volts direct current. The new station at Castelnuovo will also serve this railway.

Report of the Cambridge Observatory, 1938–39

The work carried out at the Cambridge Observatory under the directorship of Sir Arthur Eddington includes photo-electric observations for the purpose of testing the constancy of the light of stars similar in physical constitution to the sun (dwarf *G* stars). With the Northumberland equatorial, 165 measures of double stars were made, 51 being less than $1''$ in separation. Dr. Woolley began laboratory experiments in preparation for a determination of the sun's apparent magnitude, planned, in conjunction with Mr. C. R. Davidson, to be carried out in South Africa in 1940. The apparatus had been brought to a stage at which it is possible to measure with a probable error of 0·01 mag. the transmission in sensibly monochromatic light of a dark glass cutting down three magnitudes. The polarization of a spectrograph was carefully determined in several wave-lengths, and a preliminary determination of the coefficient of reflection from an unsilvered glass surface was made. Both theoretical and observational work have been carried out by research students: Dr. M. Krook (Isaac Newton student) investigating certain problems involving non-coherent absorption; D. S. Evans concluding his work on the influence of Stark effect on the centre-to-limb variation of the contours of the Balmer lines; J. Jeffreys (Isaac Newton student) on photometric work in conjunction with Dr. Woolley's research on the sun's apparent magnitude, and H. Corben working on relativistic quantum theory. The Director has investigated the problem of how far the properties of a star of variable polytropic index are intermediate between those of polytropes corresponding to the two extreme indexes. This research is given in *Monthly Notices*, 99, 4. By Grace of the Regent House on June 10, 1938, the Observatory was constituted a Department in the Faculty of Mathematics, and the Observatory Syndicate was discharged. The Syndicate had been in continuous existence for 109 years, an earlier Syndicate, appointed "for considering the propriety of building an Observatory", having met from 1818 until 1824.

Plant Hormones in Horticulture

The chemical recognition of plant hormones was quickly followed by the synthesis of substances capable of initiating the formation of roots in the stems of many plants. These substances have been used in plant propagation, causing almost in a 'catalytic' manner an acceleration of the rooting process accompanied by a more profuse root system. H. L. Pearse has now reviewed the work of thirty or more investigators who have endeavoured with considerable success to apply recent scientific discoveries to horticulture in this way ("Imperial Bureau of Horticulture and Plantation Crops. Technical Communication No. 12: Plant Hormones and their Practical Importance in Horticulture". By Dr. H. L. Pearse. Pp. 88. Bibl. 248. 3*s*. 6*d*.). There follows a valuable index showing approximately one thousand examples of propagation and the treatments used. This is not a complete list, and some difficulties in presenting the results of many workers in one table have been neatly overcome; but comparative reference would have been made easier by a standardized method of stating the concentrations employed. Results obtained by the additional use of vitamin B_1 (aneurin), known to influence the growth of excised roots *in vitro*, and other substances are also brought under review. The widespread use of aneurin is not recommended as yet, although at East Malling, as elsewhere, Pearse observed some stimulation in the subsequent growth of rooted cuttings which had received small quantities of aneurin. The bulletin reports effects on other plant organs of these substances of possible application in horticulture. It is impossible to include all the latest work; there is no mention here of tetrahydronaphthylidene acetic acid, or of α-naphthylacetamide, recently shown to be active substances inducing cell division and root formation, or of plants failing to respond to treatment the anatomy of which is under investigation at Kew. This bulletin forms a well-balanced review of the subject to date, and its value is increased by its practical outlook.

Earthquake in Bulgaria

During the night of Thursday-Friday, October 19–20, strong earthquake shocks accompanied by a roaring sound were reported from Orisovo near Tchirpan in south Bulgaria. Some alarm was caused among the inhabitants but no damage was reported, and thus the earthquake appears to have been of about intensity VI on the Rossi-Forel scale (oscillation of chandeliers, visible disturbance of trees and shrubs, some startled persons leave their dwellings). This area is definitely seismic, and violent local shocks were reported from the same region on April 14 and April 25, 1928. According to K. Jankov, of the Observatory at Sofia, the most active region is to the south-east of Kustendil, where 1,420 shocks occurred between the years 1749 and 1936, some of these being so severe as intensity VII on the Rossi-Forel scale (overthrow of movable objects, fall of plaster, etc., but no damage to buildings). The majority of the shocks appear to have been of shallow focus, only affecting a small area and probably being due to slipping along an active fault. The present shock may have been of a similar nature.

Earth Tremor near Ottawa

An earth tremor of intensity IV on the modified Mercalli scale (rattling of dishes, windows, doors) shook Ottawa on Friday, October 20. No damage was done. Small earth tremors are known to occur in eastern Canada from Baffin Bay to the Great Lakes including Newfoundland, though the nearest active epicentres to Ottawa appear to be those of Timiskaming (Quebec), where there was a shock on November 1, 1935, and in the region of the Sanguenay River, where shocks have been recorded from as early as February 5, 1663, and continuing to the present time. Further information concerning the shock of October 20 is awaited from the Dominion Observatory at Ottawa.

Discovery of Comet Giacobini-Zinner

An I.A.U. telegram from Copenhagen announces that this comet was discovered by van Biesbroeck on October 15 at 1h. 17·1m. U.T. Its position is given as R.A. 16h. 21m. 27·4s., N. Dec. 1° 18′ 53″. It is described as diffuse with central condensation, magnitude 15. In the "Handbook of the British Astronomical Association, 1939", the elements and ephemeris of this comet are given by Mr. F. R. Cripps, who applied the perturbations of Jupiter and Saturn to the 1933 elements. The comet is very close to the predicted position, and it is only necessary to make the corrections for perihelion passage 0·25d. later than that given in the "Handbook".

Rapidly Moving Spots on the Planet Jupiter

Mr. B. M. Peek, president of the British Astronomical Association and director of the Jupiter Section, has observed an outbreak of small dark spots on projections at the south edge of the North Temperate Belt of Jupiter. They appear to be rotating at such a speed that a complete rotation would take place in about 9 hours 50¼ minutes. There is a remarkable similarity between these spots and those which occurred in 1880, 1891 and 1929. Astronomers in possession of telescopes with apertures of 8 inches or more should be able to see these spots.

A Large Sunspot

A large sunspot appeared over the sun's east limb on October 19 and is now crossing to the west limb, which it will reach on November 1. The time of central meridian passage of the spot is October 26·0, its latitude 8° south and its area, corrected for foreshortening, on October 20, was 1850 millionths of the sun's hemisphere.

The Night Sky in November

The moon is new on November 11 at 7·9h. and full on November 26 at 21·9h. U.T. The bright star λ Geminorum (magnitude 3·6) is occulted on November 30, the disappearance as seen from Greenwich taking place at 2h. 22·8m. at position angle 102° from the north point, and the reappearance at 3h. 37·8m. at 282°. Mars, Jupiter and Saturn are bright planets in the evening or night sky. In mid-November, Mars souths at about 18¼h., Jupiter at 20¼h. and Saturn at 22¼h. Jupiter is in conjunction with the moon on November 21 at 22h. and Saturn on November 24 at 1h. Uranus is in opposition on November 13, when its distance from the earth is nearly 1,731 million miles. Neptune, near the border between the constellations of Virgo and Leo, makes a near approach (about 20″) to the eighth magnitude star BD + 3° 2549. At about 21h. in the middle of the month, the Milky Way passes from the eastern to the western horizon through the zenith of London. The most distant celestial object that can be seen with the naked eye—the Great Nebula in Andromeda—is on the meridian at an altitude of 79°. Vega is the brightest star in the north-west quadrant of the sky and Capella the brightest in the north-east. The Pleiades cluster is well above the eastern horizon, and Orion is then just rising. The Leonid meteors should be looked for about November 14–16; their radiant point, preceding γ Leonis, rises about 23h. The meteors of this well-known shower are characterized by swift flights and their greenish colour. Light variations in the variable star Algol (β Persei) may be noticed about one and a half hours before and after the following times of primary minima: November 14d. 3·1h.; 16d. 23·9h.; 19d. 20·8h. and 22d. 17·6h.

Military Service and the Professional Institutions

STEPS have been taken to ensure that members of all classes of the leading engineering and professional institutions, when called up for military service, will be posted to units in which their services will be best employed in the national interest and, in the case of graduates and students, to units in which the training will be of use to them on returning to civilian work. Members of engineering institutions should mention the fact when supplying particulars of their qualifications to 'interviewing' officers; a letter stating class of membership should be obtained from the Institution concerned for presentation to the officer.

Modern Wireless Communications

IN response to a request and with the view of meeting the needs of students and others who may wish to qualify for possible future service in the uniformed and non-uniformed radio branches of the Defence Forces, arrangements have been made by the Royal Institution for a series of lectures on modern wireless communications. The course will consist of twelve afternoon lectures, commencing on October 31, and will be given by Prof. C. L. Fortescue, Dr. R. L. Smith-Rose and Dr. E. V. Appleton. They will deal with important aspects of the installations, transmission of the signals and the phenomena of radio wave propagation. Tickets, for which there will be no charge, may be obtained from the General Secretary, Royal Institution, Albemarle Street, London, W.1.

The British Empire Naturalists' Association

THE British Empire Naturalists' Association has decided to suspend further publication of its quarterly journal *Country-Side* during the war, but in order to continue the maximum amount of activities, full power has been given to the various branches to carry on under their own organization until such times as normal conditions return. There will be circulated, however, the usual quarterly issues of the *Branch News*, in order to keep branches in contact with headquarters. The decision was made not without regrets, but the view maintained was that by conserving funds now, the Association would be in a stronger position to resume its full activities when peace returns, rather than to weaken itself by struggling against the rising costs and difficulties of voluntary labour. Numerous provincial natural history societies have cancelled their programmes, and others have adopted a method of meeting in the afternoons.

Institute of Metals

DURING the War the Institute of Metals is continuing its activities, other than those of a social character. The headquarters in Grosvenor Gardens, London, remain open, and the Joint Library and the Information Department are available to members. The *Monthly Journal* will continue to publish original papers, and also to provide abstracts, the importance of which becomes more apparent as members find it difficult to obtain access to technical journals.

Royal Geographical Society

THE Royal Geographical Society will, so long as is possible, carry out its programme of meetings for the session, but at modified times. All meetings will be at 5 p.m.; the evening meeting programme on alternate Mondays, the afternoon meeting and geographical films programme on the intermediate Mondays. At the first meeting, on Monday, October 30 at 5 p.m., Mr. F. Kingdon Ward will read a paper on "Six Months in the Assam Himalaya". The Asia Lecture will be delivered by Dr. G. M. Lees on November 27.

Announcements

MR. PERCY R. LOWE has been awarded the Verner von Heidstam Gold Medal of the Royal Swedish Academy of Sciences in recognition of his "important and successful endeavours to further the protection of the world's fauna, endeavours of great benefit also to the migratory birds of Sweden".

AT the annual statutory meeting of the Royal Society of Edinburgh held on October 23, the following officers were elected: *President*, Prof. E. T. Whittaker; *Vice-Presidents*, Principal J. C. Smail, Prof. J. Walton, Dr. James Watt, Dr. Leonard Dobbin, Mr. J. A. Inglis and Prof. R. Stockman; *General Secretary*, Prof. James P. Kendall; *Secretaries to the Ordinary Meetings*, Dr. A. C. Aitken and Prof. R. J. D. Graham; *Treasurer*, Dr. E. M. Wedderburn; *Curator of the Library and Museum*, Dr. J. E. Mackenzie.

THE Rockefeller Foundation has recently awarded two grants, of 350,000 and 90,000 dollars, to the Johns Hopkins University School of Medicine, Baltimore. The larger sum is to be used over a ten-year period to equip and maintain a department of preventive medicine, while the second grant will be utilized as a research fund to be distributed among departments and to projects which stand in greatest need of carrying out research programmes.

MESSRS. FLATTERS AND GARNETT, LTD., 309 Oxford Road, Manchester, 13, have issued an abridged list of their microscope slides, dealing chiefly with biological subjects. This includes two sets, of thirty-six slides each, suitable for the zoology and botany respectively of Higher School Certificate and 1st M.B. students. The firm has a stock of 30,000 slides; no change has been made in prices.

PROF. S. CHAPMAN has noted some misprints in his article on the meeting of the International Union of Geodesy and Geophysics published in NATURE of October 21: p. 717, col. 1, line 10 from bottom, for "Signole" read "Signore"; line 9 from bottom, for "Lütschy" read "Lütschg"; p. 718, col. 2, line 5 from end of article, for "Sánchey" read "Sánchez". He also intended to emphasize the complete absence of French and Italian delegates and of Russian visitors, referred to in the article.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 755.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Taste-testing the Anthropoid Apes

At the recent International Congress of Genetics at Edinburgh, in the course of discussions on the possibility that the blood-group frequencies found in man were determined by a balance of selective influences, it occurred to one of the authors that evidence on the parallel possibility for taste-testing could be obtained by testing the anthropoid apes.

By the courtesy of Prof. F. A. E. Crew and Dr. Gillespie of the Edinburgh Zoo, a preliminary test was carried out before the Congress ended, which was successful in showing that, when the animals are calm and free from interference by others in the same cage, the test can be made without ambiguity, and that both tasters and non-tasters exist among the chimpanzees.

We have since tested nearly all the anthropoid apes in the Zoological Society's collections at Regent's Park and Whipsnade. The solutions used contained 2 per cent sucrose to make them moderately attractive, and, except for this, were equivalent to Nos. 3, 6 and 9 of the standard series used at the Galton Laboratory, where they were prepared. They contained respectively 6½, 50 and 400 parts per million phenyl-thiocarbamide. Human tasters would generally find the first perceptibly bitter, but not necessarily unpleasant if the sugar were desired; the second would be, to most tasters, unpleasantly bitter, and the third decidedly so. Non-tasters might notice some slight bitterness at the strongest level. The apes tested must have similar sensory perceptions at these strengths, for those classified as non-tasters continued to accept the strongest solution, while the 'tasters' showed reluctance or aversion, sometimes with the weak, and always with the medium solution. The strong solution was used whenever possible for confirmation.

With the exception of one chimpanzee, which was too shy to be tested, the results are shown in the following table (E, R, and W stand for Edinburgh, Regent's Park and Whipsnade):

Chimpanzees tested

	Females			Total	Males			Total	Both sexes
	E	R	W		E	R	W		
Tasters ..	2	7	2	11	4	2	3	9	20
Non-tasters ..	1	1	1	3	1	3	–	4	7
Total ..	3	8	3	14	5	5	3	13	27

Thus the chimpanzees show 7 non-tasters out of 27, or 26 per cent. Experience with man also gives regularly about 25–30 per cent.

The young female Jaqueline, both of whose parents are in the Regent's Park collection, and both non-tasters, was omitted from the table of frequencies, since her reaction as non-taster, while it confirms the genetical similarity of the situation in the apes and in man, adds nothing to our knowledge of the gene frequency in the apes.

With the orang-utan we found one male non-taster at Edinburgh, and two tasters, male and female, at Whipsnade. Two male gorillas at Regent's Park were both tasters. Two Whipsnade specimens of the gibbon (*Hylobates concolor*) were both tasters, but *H. lar lar* and *H. lar agilis* at Regent's Park were non-tasters. Numerous tests on primates and other mammals are in progress.

The existence of a dimorphism in the taste test, parallel to that known in man, in at least two of the manlike apes, is a most remarkable fact. Its significance is emphasized by the circumstance that, certainly in the chimpanzee, the proportion of tasters to non-tasters is nearly the same as in human populations, which, as Boyd has shown, vary somewhat among themselves. Without the conditions of stable equilibrium it is scarcely conceivable that the gene-ratio should have remained the same over the million or more generations which have elapsed since the separation of the anthropoid and hominid stocks. The remarkable inference follows that over this period the heterozygotes for this apparently valueless character have enjoyed a selective advantage over both the homozygotes, and this, both in the lineage of the evolving chimpanzees and in that of evolving man. Wherein the selective advantages lie, it would at present be useless to conjecture, but of the existence of a stably balanced and enduring dimorphism determined by this gene there can be no room for doubt.

Acetylphosphate and Pyruvate Oxidation

Lipmann has recently reported[1] that adenylic acid is partially phosphorylated to adenosine polyphosphate by preparations of *Bacterium Delbrückii* in the presence of acetylphosphate, and suggested that this compound may be an intermediate in the oxidation of pyruvic acid generally. If so, acetylphosphate should give an increased oxygen uptake with enzyme preparations which oxidize pyruvic acid completely.

We have prepared acetylphosphate by the method of Kämmerer and Carius[2] and confirmed Lipmann's observation that the stability of the bound phosphate is similar to that of phosphocreatine. Traces of Ag^+ left in solution strongly inhibit respiration; we therefore removed Ag^+ by addition of sodium chloride and adsorption on kaolin. A neutralized solution containing a mixture of mono-, di, and triacetylphosphate was used.

Acetylphosphate is not oxidized by a dialysed brain dispersion[5] (pigeon) in the presence of phosphate, fumarate, and adenylic acid. A typical experiment is given in Table 1. Each sample contained 1·5 ml. enzyme (dialysed 4 hours), phosphate buffer (pH 7·3), 1·2 mgm. sodium fumarate, and 1 mgm. adenylic acid (total volume of 2 ml.).

Table 1.

μl. oxygen uptake in 30 minutes (air, 38°).

Blank	Acetyl-P (1·12 mgm. P)	2 mgm. sodium pyruvate	Acetyl-P + sodium pyruvate
89	66	496	450

Experiments with muscle extract, in which a rapid transfer of phosphate to adenylic acid from phosphate donators such as phosphopyruvic acid takes place, have been negative with acetylphosphate. The experiments of Table 2 were carried out with an acetone powder extract from rabbit's muscle dialysed 4 hours. Each sample contained (in 1·5 ml.) 1 ml. extract plus phosphate buffer (pH 7·3), adenylic acid (with 0·35 mgm. P), and either phosphoglyceric acid (0·8 mgm. P) or acetylphosphate (1·95 mgm. P) as phosphate donators. Phosphate was determined colorimetrically by the method of Lohmann and Jendrassik.

Table 2.

P donator	Incubation at 30°	mgm. direct P	mgm. pyrophosphate P
Phosphoglyceric acid	5 min.	0·37	0·49*
"	30 "	0·38	0·56*
Acetyl-P	30 "	2·16	0·00
"	60 "	2·30	0·04

*Theoretical value for complete phosphorylation of added adenylic acid to adenosine triphosphate, 0·70 mgm. P.

These results indicate that acetylphosphate is neither an intermediate in the oxidation of pyruvic acid by brain nor does it act significantly as a donator of phosphate to adenylic acid in muscle extract. They do not exclude the possibility that acetylphosphate might be an intermediate in the dehydrogenation of pyruvic to acetic acid by preparations of *Bacterium Delbrückii*, but the fact that some acetic acid is produced when pyruvate is oxidized by brain[4], and the indirect nature of Lipmann's evidence, make it more probable that there is some other, as yet unknown, phosphorylated intermediate common to both bacteria and animal tissues. The existence of such an intermediate is strongly suggested by the observation of Banga *et al.*[7] that adenylic acid is involved in a stage of pyruvate oxidation by brain beyond that of oxidative decarboxylation.

We are indebted to the Nuffield Trustees and the Rockefeller Foundation for grants in aid of this work.

Oxidation of Methyl Esters of Monocarboxylic Fatty Acids by Normal and Neoplastic Tissue

The metabolism of the fats in tumours has been little studied. Haven[1], feeding elaidin to rats, the method used by Sinclair[2] in classifying phospholipids into the metabolic and the non-metabolic type, found that the phospholipids of tumours are mainly of the non-metabolic type, having to do with cellular structure rather than with the burning of fatty acids for energy. According to Kisch[3], the Jensen sarcoma does not oxidize the low fatty acids. I have observed[4] that the oxygen uptake of slices of various experimental and human tumours is not increased when saturated and unsaturated monocarboxylic fatty acids in the form of sodium salts are added to the medium, and that in no instance were acetone (ketone) bodies formed. The β-hydroxybutyric acid, on the other hand, is oxidized into aceto-acetic acid.

The latter data exclude the fact that the neoplastic cell can β oxidize fatty acids. My aim was to find out whether the tumour could oxidize fatty acids by means of ω-oxidation.

I have studied manometrically the oxidation of methyl esters of monocarboxylic fatty acids from C_1 to C_8 in comparison with the corresponding free acids, in the presence of tissue slices of liver, kidney, spleen, brain cortex, striated muscle, Rous I sarcoma, round cell chicken sarcoma, and Ehrlich adenocarcinoma. It has been found that, without exception, the oxygen consumption of normal tissue slices is increased by fatty acids esters much more than by the free acids. For example, some esters increased the oxygen uptake in the liver eight times, in the brain cortex eleven times, and in the spleen seventeen times more than the corresponding acids. As a rule, the oxygen uptake increases as the fatty chain increases up to a maximum at about C_6–C_7, and decreases at about C_8, owing to the low solubility in water of this ester. With methyl formiate—in connexion with which a true ω-oxidation is obviously impossible—it is the ester which is mostly burnt in certain tissues (spleen, brain, striated muscle). Only the fatty acid component of the esters is burnt, whereas the alcohol component is not.

Neoplastic tissues do not oxidize the free fatty acids but actively oxidize the corresponding esters. The neoplastic cell in which enzymes of β-oxidation are lacking—with the exception of the enzyme which transforms the secondary alcoholic group of the β-hydroxybutyric acid into a ketonic group—can, by means of the ω-oxidation enzymes, use the fats as a source of energy.

A Cell-free Enzymatic Model of *l*-Amino-acid Dehydrogenase ('*l*-Deaminase')

Attempts to obtain cell-free enzyme preparations of animal origin effecting deamination of the *monocarboxylic* *l*-amino acids have hitherto been practically unsuccessful. (Specific enzymes deaminizing *d*-amino-acids and *l*-amino *dicarboxylic* acids have been obtained in solution and purified by several authors.) H. A. Krebs[1] attributes the deamination of *l*-amino-acids to an enzyme, termed '*l-deaminase*', depending for its activity upon the integrity of cell structure and rapidly deteriorating when the cells are damaged.

It appears from the data of Krebs that '*l*-deaminase' is even more sensitive to the dilution of cell-contents in ground tissue suspensions than to cell destruction as such, and further, that the *di*carboxylic amino-acids are oxidized at a very much higher rate than the *mono*carboxylic ones (in fact, *l*-aspartic acid was the substrate used in most experiments).

These facts point to the complex nature of '*l*-deaminase'. In a recent paper[2], one of us (A.B.) suggested that deamination of monocarboxylic amino-acids might proceed by way of their transamination with α-ketodicarboxylic acids, followed by deamination of the resulting amino*di*carboxylic acids, owing to co-operation of two enzyme systems: glutamic or aspartic aminopherase, and glutamic or aspartic dehydrogenase (with their respective co-enzymes, or hydrogen and amino carriers). The chain of reactions involved would be a reversal of the mechanism of amino acid synthesis in the animal body recently suggested by Euler and associates[3].

In support of this hypothesis, we have succeeded in constructing, from the above-stated constituents, a cell-free, almost water-clear enzymatic model system, deaminizing *l*(+)alanine at a fairly high rate under aerobic conditions, with pyocyanine as autoxidizable hydrogen carrier. The complete system consists of: (*a*) 2 ml. purified and dialysed glutamic dehydrogenase (from ox liver, after Euler[3]), (*b*) 3–4 ml. purified and dialysed glutamic aminopherase (from pig heart, after M. Kritzmann[4]); (*c*) 2–20 mgm. (14–138 mol. × 10^{-6}) α-ketoglutarate; (*d*) 2·5 mgm. cozymase (of about 60 per cent purity, after Ohlmeyer); (*e*) 0·3 mgm. pyocyanine; (*f*) 15–20 mgm. (170–225 mol. × 10^{-6}) *l*(+)alanine; (*g*) $M/15$ phosphate buffer, *p*H 7·6 to 10 ml. total volume.

In the complete model system, 10–15 per cent of the total amino-nitrogen is liberated as ammonia in the course of two hours shaking in an atmosphere of oxygen (Table 1).

TABLE 1.

Expt. No.	I	II	III	IV (3 hours)				V (4 hours)
α-Ketoglutarate (mols × 10^{-6})	160	135	117	117	58	29	14	6
	Ammonia liberated in 2 hours, mol. × 10^{-6}							
Complete system	23·6	12·9	24·3	23·6	21·0	20·0	17·0	19
Without glutamic aminopherase ..	0	1·6	—	—	—	—	—	—
Without glutamic dehydrogenase	5·6	0·7	2·0	0	—	—	—	—
Without ketoglutarate	0	0	0	0	—	—	—	—
Without cozymase . ..	—	0	—	0	—	—	—	—
Without alanine . .	0	0·7	0·7	0	—	—	—	—
Without pyocyanine .. .	0	—	—	—	—	—	—	—

In the same system, the direct deamination of *l*(+)glutamic acid proceeds more than twice as rapidly. Methylene blue may be used instead of pyocyanine, but the latter is more efficient. Practically no ammonia is formed from alanine if any one of the constituents is omitted. With low concentrations of ketoglutarate, it is advisable to add sodium arsenite in order to prevent breakdown of the keto-acid (glutamic dehydrogenase proved resistant to arsenite, like '*l*-deaminase').

Whether the 'indirect' mechanism of *l*-amino acid oxidation here discussed is actually at work in the metabolism of living tissues must be ascertained by special studies, now in progress in this laboratory.

Localization of Electrolytes in Muscle

THE volume of the free interspaces within the freshly excised sartorius of the frog has a mean value of 9 ml./100 gm. when measured by inulin agreeing with the results from the magnesium method[1]. (The inulin method when applied to rabbit muscle[2] after preliminary injection into the blood stream gives 7 ml./100 gm.)

Comparing this figure with that for chloride in muscle, which is 14 per cent that in the plasma, it will appear that all the chloride is not free in the interspace water. That the difference is mostly due to the penetration of the fibre membrane by chloride is shown by the evidence now accumulated in this laboratory. Here some of the facts immediately related to the chloride and sodium localization are given.

(*a*) When immersed in sulphate solution (1·3 pe cent sodium sulphate) the chloride in the freshly excised sartorius comes out entirely within abou twenty minutes, but when immersed in glucose solution (3·2 – 3·8 per cent) it diffuses in two parts The first. corresponding to the interspace fluid, comes out rapidly, nearly if not quite as rapidly as in sulphate. The second and comparatively small fraction takes upwards of three hours for complete emergence. During the first period the potassium diffusing out is much less than either chloride o sodium, but during the second period it is considerably greater.

(*b*) Even when immersed in a solution resembling as closely as possible the inorganic composition of plasm (including carbon dioxide with glucos to maintai the osmoti balance, th chloride in th sartorius increases to 2 per cent of th external chloride within about twenty minutes and then remain steady. During this time sodium increases by onl 4 per cent of the external sodium, and this i accounted for by a corresponding loss of potassium There is no correspondence between the movemen of sodium and chloride, which negatives an adsorption explanation of the increased chloride, but i easily accounted for by an interchange with othe permeable anions within the fibre.

The chloride, so increased by preliminary immersion, diffuses into glucose solution in two parts a before, the second being now much increased ove the similar fraction of the normal content, wherea the first remains the same.

(*c*) Sodium diffuses from the fresh sartorius int glucose solution in a very similar manner to chloride the second sodium fraction taking likewise three t four hours for complete emergence.

(*d*) When all or practically all the sodium o chloride has emerged from the sartorius into glucose solution, the potassium is still present in considerabl quantity (50–60 per cent of the original content) an continues to diffuse out.

We may deduce that about 9 per cent of th external sodium or chloride is contained in the fre interspaces and can diffuse out rapidly, the remainde of the chloride and sodium being contained within the fibre. The fact that practically all the sodium and chloride diffuse out with less than half the potassium shows that a considerable proportion of of this exists in some region free from sodium and chloride or with a mere trace of chloride. This region we may identify with the myofibril, and regard sodium as being present only in the sarcoplasm.

The presence of a second membrane with somewhat different permeabilities is shown by the fact that in Ringer[2] at 2–3 C. potassium has diffused out to one half or so of its full amount, and sodium has entered in corresponding quantity, but within the next three days there is almost no change in the potassium or sodium content. After four or five days there is a sudden emergence of the remaining potassium and corresponding entrance of sodium accompanied by considerable swelling.

The above research has been supported by a grant to one of us from the Irish Medical Research Council.

Source of the Moulting Hormone in Rhodnius (Hemiptera)

Two known factors are concerned in the control of growth in Rhodnius: a 'moulting hormone' which initiates cell division and subsequent ecdysis, and an 'inhibitory hormone', secreted in the first four nymphal stages, which prevents the development of imaginal characters. The inhibitory hormone is secreted by the corpus allatum[2].

I originally suggested that the moulting hormone might come from the same gland[1], but I have been unable to produce satisfactory proof of this. Recently I have re-investigated the question by transplanting isolated corpora allata, brains and parts of brains from 5th stage nymphs shortly after the 'critical period' into 4th stage nymphs decapitated at twenty-four hours after feeding.

In no case (11 experiments) did implantation of the corpus allatum and the associated sympathetic ganglion induce moulting; in 15 out of 17 experiments, moulting was induced by implantation of the brain. When different parts of the brain were tried, negative results were obtained with the suboesophageal ganglion, the optic lobes and the ventral half of the central mass of the brain; large pieces of fat body also gave negative results.

Positive results were obtained only with the dorsal half of the central mass of the brain. This is the region in which Hanström has recently demonstrated in Rhodnius the presence of peculiar large nerve cells which may have a secretory function[3]. I have confirmed the presence of these cells but have been unable to satisfy myself that they show histological signs of increased secretory activity during moulting.

A Peculiar Phenomenon Observed in Larval Populations of the Flour Beetle *Tribolium confusum* Duv.

I have observed that if small masses of coarsely sifted whole-wheat flour (64 gm. in a 150 c.c. beaker) are seeded with more than 800 eggs of the flour beetle *Tribolium confusum* Duv., and maintained at a suitable temperature and relative humidity (27° C., and 75 per cent r.h.), a peculiar distortion of the originally flat, level, upper surface of the flour mass occurs. There is a slight initial bulging upward commencing on the sixth day when the eggs hatch, no doubt due to the loosening of the flour by larval movement. This bulging increases up to about the twenty-first day, as shown in Fig. 1. There then takes place a more or less rapid moulding of the surface into the rather graceful form seen at the bottom of Fig. 1, and in Fig. 2, which is a photograph of a median vertical section of a culture on the twenty-eighth day.

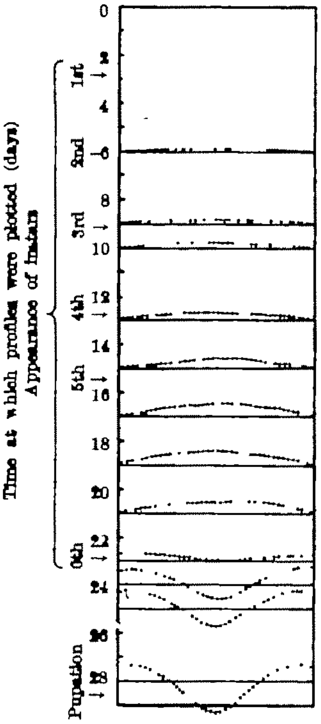

Fig. 1.

The horizontal lines are the original flour surface.

It will be noted from Fig. 1 that the distortion is not due to a mere sinkage of the central parts, but to a radial translocation of the flour, the circumferential drop being due, it is believed, to peripheral migration of the larvæ. The degree of distortion of the original flat surface depends on the number of larvæ present, being almost imperceptible with 600, marked with 800, and extreme with 1,600, there being almost 0·75 inches between the highest and lowest parts at this last concentration. With more than 1,600, interference between the moving larvæ occurs, and the figure is less marked.

The effect is dependent also on the diameter of the vessel, the optimum diameter appearing to be about 2 in., which is that of a 150 c.c. beaker. The effect does not occur if the flour is very fine, probably due to higher internal friction in such flour. Vertical

X-ray photographs do not disclose any marked non-random distribution of the larvæ, though some small evidence of peripheral migration is afforded by the presence of circumferential tunnels.

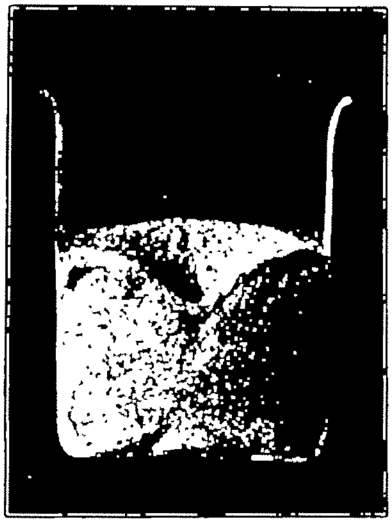

Fig. 2.

This problem is being investigated experimentally, and also from the point of view of a mathematical analysis, and will be reported on later in a publication made elsewhere. I wish to acknowledge the financial support of the National Research Council of Canada and the Science Research Committee of Queen's University in connexion with the work on the growth of populations of Tribolium, of which this is a part.

Limits of Validity of Quantum Mechanics

We proposed some years ago[1] a modification of the formalism of the quantum theory for the cases in which the following condition is satisfied:

$$\xi = \left|\left(\vec{p}_1 - \vec{p}_2\right)^2 - \frac{1}{c^2}\left(E_1 - E_2\right)^2\right| \gtrsim p_0^2 \qquad (1)$$

$$p_0 = \frac{h}{r_0} \sim 137\, mc,$$

where $\vec{p}_1$, E_1 and $\vec{p}_2$, E_2 are 4-vectors corresponding to two states of a particle in a quantum transition, and r_0 is a universal length, $r_0 \sim 10^{-13}$ cm.

Such a method consists in the introduction of some relativistic 'convergency-factors' $G(\xi)$, which $\rightarrow 0$ if $\xi \rightarrow \infty$ and which give rise to convergent results instead of many divergent results of the present quantum theory. In the cases where $\xi < p_0^2$, $G(\xi) \cong 1$ and the rules of the ordinary quantum theory are obviously obtained. This condition $\xi < p_0^2$ is therefore the condition of validity of the quantum mechanics and it can be examined independently of the method of the 'convergency-factors'.

Let us show that by operating within the limits of validity of the present quantum theory, the measurement of a co-ordinate x cannot be made with $\Delta x < r_0$. Such a measurement can only be performed by using incident waves of a wave-length $\lambda < r_0$ and by operating in such a manner that the scattered radiation which enters the measuring apparatus (for example, the Heisenberg microscope) has also a wave-length[2] $\lambda < r_0$; $|\vec{p}_2| > p_0$.
We have indeed:

$$\Delta x \cong \frac{\lambda_2}{\sin\, \alpha}. \qquad (2$$

Thus we can suppose

$$|\vec{p}_1| \gtrsim |\vec{p}_2| \gg p_0 > mc,$$

and, from the condition of validity of quantum theory $\xi < p_0^2$, we obtain the following condition for the angular deviation Θ in the collision process:

$$\xi = \vec{p}_1^{\,2} + \vec{p}_2^{\,2} - 2\,|\vec{p}_1|\,|\vec{p}_2| \cos\Theta - (E_1 - E_2)^2 \sim$$

$$2\,|\vec{p}_1|\,|\vec{p}_2|\,(1 - \cos\Theta) < p_0^2. \qquad (3$$

$$\left(2 \sin\frac{\theta}{2}\right)^2 < \frac{p_0^2}{|\vec{p}_1|\,|\vec{p}_2|};\;\; 0 < \frac{p_0}{p_2};\;\; (|\vec{p}_2| = p_2).$$

Only by operating within these limits can we b sure of not introducing unknown phenomena and o being able to apply the ordinary rules of the quantum theory. But in the case we are dealing with, wher the measuring apparatus is, for example, a γ-ra microscope, we can only use scattered particle within a small angle α. The numerical aperture o the microscope $\sin\alpha$ must satisfy the condition

$$\sin\alpha < p_0/p_2. \qquad (4$$

From (2) and (4) we have

$$\Delta x \gtrsim \left(\frac{h}{p_2}\right) \Big/ \left(\frac{p_0}{p_2}\right) = r_0. \qquad (5$$

The nuclear phenomena belong to the conditio $\xi \sim p_0^2$. It is very remarkable that, in the cosmi radiation, phenomena belonging to the conditio $\xi \gg p_0^2$ have not been observed so far. This seem to justify the assumption that such phenomena hav a very small probability of occurrence, a fact i agreement with the assumptions of the method of th 'convergency-factors'[3].

Hyperfine Structure in the Spark Spectrum of Iodin

In a recent short note[1], Th. Schmidt states th he cannot agree with my measurements and con clusions relating to the hyperfine structures of tw lines in the iodine spark spectrum. In my analys of 33 terms in this spectrum[2], I found that in eigl there were deviations from the interval rule. Among these the terms with $J = 2$ did not fit the quadrat interaction law of the type suggested by Schüler ar Schmidt[3] and by Casimir[4], but could be fitted in a cubic law:

$$E = A + B \cos IJ + C \cos^2 IJ + D \cos^3 IJ.$$

In particular, I have found it necessary to empl this formula for the structure of (${}^2D$) $6s$ ${}^3D_2$, whi has been derived with a high degree of exactness from the line 6127. This same line has been measured by Schmidt, who obtains very different results, leading to a different term analysis. An entirely independent analysis for the term in question has recently been published by Murakawa[5], who has achieved high resolution in analysing the structures of the lines 5407, 5678, both of which involve the above term.

In the accompanying table are given the intervals derived for (^3D) 6s $^3D_2$, by Schmidt, Murakawa and myself. In addition, I have independently analysed Murakawa's *experimental* data and have enclosed the results in brackets. It should be pointed out that the nature of the lines 5407, 5678 is such that errors due to overlapping might cause small displacements, but *only* in the lower F levels.

F	Schmidt	Murakawa		Tolansky
9/2				
7/2	246	236	(235)	234
5/2	227	236	(237)	238
3/2	182	181	(181)	185
1/2	117	114	(114)	110

It will be observed that Schmidt's data differ onsiderably from those of Murakawa and myself, particularly in the first two intervals, which are the very ones in which the accuracy of my measurements is at its best (± 1 unit). It appears that the position of $F = 7/2$ is incorrectly given by Schmidt, since Murakawa and I are in agreement.

I wish to re-emphasize strongly what I have previously stated, namely, a cubic interaction formula need not of necessity imply the existence of a nuclear *octopole* moment. I suggest that it is possible that the existence of configuration interaction will convert the quadratic expression characteristic of electrical quadrupole moment into a cubic interaction law, the size of the cubic term depending upon the degree of configuration interaction. It is to be hoped that theoretical workers will examine this effect, since, if configuration interaction can distort hyperfine structures, *no* reliance can be placed upon any calculated nuclear electrical quadrupole moment until the existence of such interaction can be excluded with certainty.

S. Tolansky.

Points from Foregoing Letters

Human beings can be divided into two groups according as they experience a bitter taste or not with dilute solutions of phenylthiocarbamide, and the proportion of 'non-tasters' to 'tasters' is regularly 5–30 per cent. Tests by R. A. Fisher, E. B. Ford, nd J. Huxley on manlike apes in zoological collecions show that some of them cannot taste phenylhiocarbamide. The proportion of non-tasters in the chimpanzee agrees with that in man. It appears hat in the ancestries both of man and of the apes balance of selective forces must have maintained he gene ratio at a nearly constant value.

S. Ochoa, R. A. Peters and L. A. Stocken find that acetylphosphate is not oxidized by brain enzyme preparations and does not transfer its phosphate to adenylic acid in muscle extracts. They conclude hat the compound is not an intermediate in the oxidation of pyruvic acid by brain.

E. Ciaranfi finds that the esters of fatty acids increase the oxygen consumption of normal tissue lices much more than the fatty acids themselves; only the fatty acid component of the esters is onsumed. Neoplastic tissues do not oxidize he free fatty acids but actively oxidize their sters.

A. E. Braunstein and S. M. Bychkov claim that hey have obtained a cell-free enzymatic system able to deaminize *l*-alanine at a fairly high rate under aerobic conditions and with pyocyanine as autoxidizable hydrogen carrier.

Using an inulin method, the volume of the interspaces in the excised sartorius of the frog is shown by E. J. Conway *et al.* to be 9 ml./100 gm. muscle, whereas the chloride represents 14 per cent of the external concentration. This, supported by other facts, indicates the presence of chloride within the fibres. Evidence is given for the localization of sodium within the sarcoplasm and the existence of a second membrane, presumably that of the myofibril, which can, under certain conditions, show permeabilities differing from those of the sarcolemma.

V. B. Wigglesworth has induced moulting in decapitated nymphs of Rhodnius by implantation of the brain removed from other nymphs during the 'critical period'. Implantation of the corpus allatum and sympathetic ganglion gave negative results.

When a small quantity of coarsely sifted wholewheat flour in a beaker is seeded with eggs of the flour beetle and conditions favourable to development are maintained, J. Stanley finds that the surface of the flour gradually assumes a distinctive form. The effect appears to be due to radial movement of the flour.

By the introduction of certain relativistic convergency factors, G. Wataghin deduces the condition for the rules of the ordinary quantum theory to hold, and examines these conditions by an independent method.

S. Tolansky criticizes the hyperfine structure measurements in the iodine spark spectrum published by Th. Schmidt. It is suggested that a quadrupole quadratic interaction formula might be converted into a cubic formula, as a result of configuration interaction.

RESEARCH ITEMS

Finger Weaving in Canada

The question whether the brightly coloured sash and garters of the Indians of Canada are of native origin and whether finger weaving, which they involve, is a pre-Columbian technique or an introduced feature which adapted itself to new surroundings, is considered by Marius Barbeau in "The Assomption Sash" (National Museum of Canada: *Bull.*, 93, *Anthrop. Series*, **24**; 1939). The Assomption and Achigan sashes are so called from their place of manufacture as a home industry of the French Canadians for the fur traders of Montreal to barter with the Indians. They were also known as arrow sashes from their pattern, which includes a row of continuous arrow heads; and although there were others known by appropriate names, the arrow sash became the standard type, when the Hudson Bay Company nearly forty years ago began to import a cheap manufactured sash from England, as it does still; this ruined the home industry, and attempts have been made recently to revive it. Research directed to the character of the older sashes preserved in museums in America and Europe, and study of the technique of finger weaving and its distributions has failed to produce evidence of its practice in Europe, which would account for its introduction into Canada in Colonial days. The Indians when they wore belts—and this seems to have been exceptional before 1800—were strongly under the influence of the French; but there is no evidence of finger weaving in France, or elsewhere in Europe, except only in Norway and possibly Lapland, where finger woven garters are made. It is possible that it was a traditional handicraft in other European countries and has been forgotten. The alternative would seem to be that it was, as demonstrated by Wissler and Amsden, a type of weaving widely diffused in prehistoric and historic America, which was adopted from the Indians and further elaborated by early French colonists.

Periodicity of Influenza

Various attempts have been made to determine the periodicity of influenza epidemics. If this could be done, it would be possible to foretell when an epidemic might be expected and to take some measure in advance for dealing with it. Brownlee in 1919–23 accounted perfectly for the outbreaks from 1890 to 1895 on the basis of a 33-week cycle, but this 'one phase' theory failed for the series of waves after 1895. Douglas Webster now claims that by adopting a 'two phase' theory, the epidemic waves of influenza may be accounted for (*Edinburgh Med. J.*, 46, No. 9, 591). The standard period is 33 weeks, with a ± 3 weeks' variation (phase 1), though missed periods often occur. Sixteen to seventeen weeks after the peak of a phase 1 major epidemic, a phase 2 minor epidemic is likely to occur and to be repeated every 33 weeks or thereabouts; that is, a major or minor epidemic tends to occur every 16 or 17 weeks with occasional misses. On this basis, all the epidemics from 1918 to February of this year appear to be accounted for, and a major epidemic is due in February, 1941, with a phase 2 epidemic of some severity in February, 1940.

The Panama Canal as a Fish Highway

Has the opening of the Panama Canal enable fishes from the Atlantic Ocean to enter the Pacific or vice versa? There is the difficulty of negotiatin the locks, and the greater difficulty for most o enduring a journey of forty miles through the fres water between the locks at the opposite ends of th Canal. Samuel F. Hildebrand to some extent answer the question in his account of the fishes which hav been found throughout the Canal and the invertebrates which inhabit the various locks (*Zoologic* 24, 15; 1939). He finds that while the locks do no form serious barriers, the difference in salinity doe and that as a consequence the fishes which occu beyond the sea-locks and are most likely to complet the journey from ocean to ocean belong to specie which inhabit almost indiscriminately salt, brackis and fresh water. These include the gobies or guavina several species of Centromorphidæ and Gerridæ, few species of burros (Pomadasys) and the tarpo Indeed the tarpon has been known to have traverse the Canal from Atlantic to Pacific on at least fou occasions. The locks shelter a varied invertebrat fauna, which includes sponges, Hydrozoa, Alcyonari Mollusca, crabs and shrimps, and these may help to sustain the migrating fishes during part of their journey

Evolution of a Sun-fish

The disk-like shape, excessive lateral flattenin and abbreviated body of a sun-fish are so unusu that special interest attaches to the elucidation the stages by which such an oddity arose. Some yea ago (1933), W. K. Gregory suggested a probabl evolution based upon skull characters; now Henry Haven, convinced that other parts of the anatom may be traced in evolution as well as the skull, h arranged what approximates to an evolutionar series illustrating the development of the locomot apparatus (*Bull. Amer. Mus. Nat. Hist.*, 76, 143 Sept. 1939). The series runs from a normal perc morph fish, the striped bass, to the acanthur Hepatus, the trigger-fish Balistes, the porcupine-fi Diodon, and by way of a hypothetical intermedia stage to the nipple-tailed sun-fish, Masturus. A lar plate illustrates very strikingly the modifications musculature and fin-arrangement which lead to t sun-fish, perhaps the most remarkable change bein the loss of a tail fin and the formation of a new pseudo-caudal fin by extension of the dorsal and an which meet around the caudal end of the vertebr column. It is surprising to learn that the characte of the alimentary tract indicate that sun-fishes a bottom-feeders, that the skin, skeleton and the lo of the air-bladder suggest that they live in de water, and that the form of the fins with the powerful muscles indicates an active existence.

Trichinosis in Pigs

An extensive survey of pigs in eastern Canada h been carried out in 1937 and 1938 with the view determining the incidence of *Trichinella spiralis*. samples were selected at random and no selecti was made, except that samples were examined on from hogs of which the district of origin was know (*Canadian J. Research*, 17, Sect. D., 151, 193

. W. M. Cameron finds that of 2,000 hogs examined, ly 15, or 0·75 per cent, were infected. In the nited States during the same years the Bureau of nimal Industry reports in 1937 an infection of 3·4 r cent where the hogs were fed on garbage and 32 per cent where they were not fed on garbage, e corresponding figures for 1938 being 10·0 per nt and 1·0 per cent. In Canada the feeding of hogs on uncooked garbage is prohibited, and Cameron's gures agree closely with the corresponding statistics om the United States. There seems little doubt, erefore, that the majority of pigs infected with ichinosis in North America owe their infection to eding upon raw garbage. Where garbage has been oked before being served to the pigs, the incidence the parasite falls to a level similar to that associated ith clean food.

ultiple Allelomorphism in Cotton

R. A. Silow (*J. Genetics*, 38, 229–276; 1939) has vestigated further the multiple allelomorph series verning leaf-shape in cotton, which now includes o further members, one from *Gossypium anomalum* d a strain of *G. arboreum*. The author shows that e two pairing complements which influenced leaf-ape (lobe- width and length) are controlled inde-ndently by the genes. In regard to lacination, the der of genes is $L^l - L^a$ and $L^a - L - l$, and in regard to be-width $L^l - L^a$ and $L - L^a$ and l. It is suggested that e gene is compound with two gene centres con-olling lacination and lobe width respectively. th field and mutant allelomorphs exhibit a similar gree of partial dominance, a situation which is ought to be different from the previously accepted minance relationships. Theories relating to the ture of gene action and dominance are discussed, d a theory is put forward that dominance is a nction of the interaction of allelomorphs, dependent on the possible expression of the particular aracter, and also upon other genes working to the me effect.

igin of the Duke Cherries

It has been suggested that the Duke cherries $n = 32$) are hybrids of the diploid sweet cherry $n = 16$) and the sour cherry ($2n = 32$). Again some ve thought that the Duke cherries are tetraploid rms of the sweet cherry. K. Hruby (*J. Genetics*, , 125–132; 1939) has investigated the problem by alysing the meiosis of the Duke cherries and of eir triploid hybrids with the sweet cherry. In ace of bivalents, as in the sour cherry, a high pro-rtion of quadrivalents are found in the Duke erries and 100 per cent trivalents are found in e third of the meiotic cells of the triploid hybrid. is provides strong evidence that the Duke cherries e auto-tetraploids of the sweet cherry.

ructures of Diacetone Dulcitols

Pizzarello and Freudenberg in 1930 proposed uctures for the two diacetone dulcitols (originally scribed by Fischer in 1915) in which they were presented as enantiomorphous, the α-compound ing 3, 4 : 5, 6-diacetone dulcitol and the β-compound 2 : 3, 4-diacetone dulcitol. The absence of optical tivity and the ready separation of the two com-unds by fractional crystallization, as well as other operties, are strongly against the structures proposed by Pizzarello and Freudenberg, and R. M. Hann, W. D. Maclay and C. S. Hudson (*J. Amer. Chem. Soc.*, 61, 2432; 1939) have now shown that the two compounds are structural isomers. The β-diacetone dulcitol is 2, 3, 4, 5-diacetone dulcitol, a *meso*-form. The α-diacetone dulcitol is 2, 3, 5, 6-diacetone-D, L-galactitol, a racemic form. A cyclic acetal shift was shown to be the cause of the unusual changes noticed by Fischer and Bergmann in the acylation of α-diacetone dulcitol, which corresponds with the passage of 2, 3, 5, 6-diacetone-D, L-galactitol to 1 : 6 dibenzoyl-2, 3, 4, 5-diacetone dulcitol.

Palladium-Deuterium Equilibrium

In continuation of the measurements of the isotherms for the absorption of hydrogen by palladium made by Gillespie and Galstaun (1936), the corresponding system with deuterium has been measured by L. J. Gillespie and W. R. Downs (*J. Amer. Chem. Soc.*, 61, 2496; 1939). The results with hydrogen were confirmed, and a series of isotherms for deuterium and palladium black was obtained from 200° to 300°, including a critical point at 276°, 35 atm. pressure and 0·25 atom D per atom Pd. A reluctance in forming the second solid phase was overcome by pretreatment with hydrogen. For a given temperature and pressure the absorption of deuterium is less than that of hydrogen; horizontal lines appear in the deuterium isotherms at pressures 2·3–2·5 times the pressures of the corresponding hydrogen horizontals. The locus of compositions of coexistent solid solutions in the phase diagram is smooth and continuous without rising steeply at any simple atomic ratio; hence it is concluded that no palladium deuterides exist in the region above 200°. As the composition of the second solid phase is practically Pd$_2$D at 200° (like the hydrogen system), further work at lower temperatures might show the existence of this compound.

Structure of Glaciers

M. F. Perutz and G. Seligman (*Proc. Roy. Soc.*, A, 172, 335; 1939) have investigated the transition of granular compacted snow (firn) into glacier ice, and the mechanism of glacier flow. The experiments were conducted on the Great Aletsch Glacier and formed part of the work of the Jungfraujoch Research Party of 1938. Samples of the glacier were taken and the size, shape and orientation of the crystals determined by the methods of optical crystallography. It was found that during the transition of firn into glacier ice the crystals grow largely by the refreezing of melt water retained in the capillaries. The firn crystals are largely oriented with their hexagonal axes normal to the glacier surface—this is ascribed to the influence of the temperature gradient present during refreezing or sublimation. In the course of 6–8 years, the crystals assume random orientation, and it appears that in the firn region there is no laminar flow, and that the motion of the glacier is due to haphazard motion of small crystalline units. This was shown by observing rows of indicating pins in pits and crevasses. In the ice region lower down the glacier both laminar and non-laminar flow occur. The crystals again become partly oriented with axes normal to the direction of flow, and the size of the crystals increases. The phenomenon is compared to the rolling of a metal sheet—it involves the growth of crystals in certain favoured orientations and their deformation by gliding.

WORK OF THE ARCHÆOLOGICAL SURVEY OF INDIA*

SIR LEONARD WOOLLEY'S report on the archæological survey of India is a comprehensive document covering in some detail the large number of problems which presented themselves to its author during his three months' stay in the country, and is characterized by a frankness of statement and freedom of criticism unusual in an official publication. It is, however, clear that with issues vital for the future of archæological studies and of interest not to India alone but also to the whole body of scholarship concerned with the scientific investigation of past civilizations, the situation necessitated plain speaking. As Sir Leonard points out, moneys from a reduced allocation from public funds were being wasted by misdirection, evidence was being destroyed through ignorance, incompetence or lack of training, and at the same time not only was no attempt being made to remedy lack of knowledge of India's cultural history or fill in the gaps in the archæological record, but also the very existence of these defects was barely realized.

The original terms of reference upon which Sir Leonard was invited to report by the India Office in March 1938 covered the most promising sites or areas for excavation; the best methods for the speedy and fruitful development of exploration activities in general, regard being had not only to Government but also to non-official agencies, such as universities, learned societies, etc.; the best method of training or selecting officers for exploration work; and finally, any general points bearing on the field of exploration and excavation not covered in the preceding.

This formulation of the problem of archæological exploration in India obviously leaves something to be desired; and Sir Leonard was unlikely to overlook its defects as the charter of any commission he could undertake. He had in mind, of course, the report of the Museums Association on the museums of India. He pointed out to the India Office that matters coming under the head of "general points" might well be of crucial importance, such as the character of the museums available for the custody of antiquities, finance, the capacities of the staff, and the like. He was assured that the more complete the report, the more it would be welcomed.

Sir Leonard began his study of the situation with some knowledge of the conditions which placed difficulties in the way of "fruitful development of exploration activities". On further examination, however, he found that his impression, gathered from the printed reports, that the unfavourable comparison of the work of the Department with that prior to the departure of Sir John Marshall in 1931 was due to financial stringency was entirely erroneous. After his inspection, he was forced to the conclusion "that the lack of money is not the principal reason for the setback in the progress of archæology in India . . . an increase in the grant unaccompanied by other changes would actually do more harm than good, for the truth is the Department is altogether lacking in men trained for the work they have to d Everywhere plenty of enthusiasm, intelligence an learning were encountered; but experience and trai ing were lacking and for this the members of th staff were not to blame."

In regard to the staff, it is further pointed o that owing to the lack of differentiation and specia ization, each member is expected to be a supe man: he is expected to be proficient in the work conservation and excavation, may at any time put in charge of a museum, and is in addition saddle with a mass of clerical work for which he has n special qualifications. Not only is differentiation i function essential, but also the training and tuitio required cannot be obtained within the departme as at present constituted. For this and other reaso Sir Leonard recommends the appointment of temporary adviser on archæology, who could de with all the points at issue.

Sir Leonard then proceeds to expand this gener criticism and to put forward his recommendatio in several chapters of his report, each dealing with so specific aspect of the situation—sites for excavation excavation by non-Government bodies, the selectio and training of officers, the work of an archæologic department, excavation museums, general, an finance and personnel.

Apart from criticism of the work of the Depa ment, the brief survey here given of the present sta of archæological knowledge of India's past is illum inating. By 1931 the work at Taxila on the Bh mound had thrown a little light on the few centuri preceding the Christian era, and Sirkap had do much for the Scytho-Parthian period. The religio monuments of the Buddhist age between the seco and fifth centuries A.D. had been well exemplified the north-west, and stray monuments of the Maurya and Gupta period had been brought to ligh Mohenjo-daro and Harappa had illustrated richly o phase of a culture about which no one could agr whether it was or was not Indian; and between and Asoka, the next of which anything at all w known, there was a gap of two thousand years blank ignorance. Of the cultural history of Ind not even the skeleton existed, and even for tho periods which may be called historical the sequen of cultural history was quite unknown. From coi and scattered inscriptions there had been construct a regnal sequence to serve as a framework of histor but that was all, and in any excavation it w impossible, unless coins or dated inscriptions we forthcoming, to fit to that framework such discoveri as might be made.

As further evidence of the little prospect of advanc ment of knowledge, reference is made to the absen of the surest basis for the establishment of a chron logical scheme of cultural history—the study pottery. Except for the pottery of the Indus cultu no information is available, and a pottery type cann be dated within a thousand years. In South Ind the position is even worse. Of the two, or possib three, phases of 'prehistoric' culture, not even t sequence or time relation has been ascertained, a

---

* A Report on the Work of the Archæological Survey of India. By Sir Leonard Woolley. Pp. ii+47. (Simla: Department of Education, Health and Lands, n.d.)

: the positive date of objects of clay, iron and ronze be demanded, the answer must allow of a argin of error of anything up to three thousand ears. Of the minor arts of the historic period othing is known at all; between 'prehistoric' and istoric there is no correlation, and so far as cultural istory is concerned, 'prehistory' may be said to ontinue to the sixteenth century A.D.

After such a scathing indictment of wasted oppor- unity, almost any recommendation would probably e acceptable; but Sir Leonard, while indicating here and on what considerations operations in the eld might be extended, wisely counsels that in resent conditions increased expenditure on excava- ion would be harmful rather than a benefit, until he work of the Department has been placed on a ound basis.

Except in so far as they are directed to ensure he increase of archæological knowledge in accordance ith scientific method, Sir Leonard Woolley's recom- endations in detail are the concern of the admin- strative authorities of the Government of India, ather than of interest to archæologists at large. In iew of Sir Leonard's long experience and his wide nd profound knowledge of the problems of archæ- gical exploration, it may be accepted that his ecommendations are such as to secure that the rchæological staff shall be fully efficient to carry on xcavations on sites chosen for their anticipated ossibilities of advancing knowledge, in co-operation with a museum service also working to that end, the service being equipped and organized in such a manner as to afford facilities for the training of future officers; while the curtailment of unnecessary and wasteful activities, especially in misdirected conservation, will avoid excessive increase in the Department's budget. One recommendation to which heartfelt welcome will be given outside India is that for the appointment of two specially qualified officers to deal with the earlier prehistoric period, namely, the stone ages.

Of wider general interest are the sections of the report which deal with excavation by bodies other than the Survey and by organizations from outside. Much disappointment has been expressed in one quarter and another that enlargement of the provisions of the Antiquities Law has failed to attract non-official excavation. Sir Leonard rightly points out that the responsibility is to be laid on a law which, liberal as it is in form, allows no prescriptive right to the excavator of a share in the finds, but leaves this open as a matter of interpretation. This and other matters, including training in excavation for officials by reservation of the right of the Department to attach one of its officers to an expedition's personnel, are covered by amendments to the law here suggested. Provision for early publication is also made; while the importance of early publication in accessible and suitable form at a reasonable price by the Survey itself is strongly urged.

THE INFORMATIVE CONTENT OF EDUCATION

THE second report of the Committee of the British Association appointed to consider the aps in the content of education to which Mr. H. G. Vells directed attention in his presidential address to ection L (Education) at Nottingham was presented at he Dundee meeting. The first report revealed a eneral agreement that Mr. Wells's suggestions were o wide in scope and too advanced for the capacity f the pupils concerned. There were, however, ifferences of opinion, and the present report shows answer to inquiries by the committee the sults attained by school-teachers in the studies ommended by Mr. Wells. He, of course, when ddressing the Association, used grown-up language itable for his audience but not for children of the ge of 7–11 years. It is clear now that much of the formation he wished to see taught can be learnt nd might be acquired with advantage by young ildren.

The results here noted and tabulated by school- achers are very promising, in view of the small ortion of time available for such teaching, and it is ally important. We are not getting at present nything like the return we are entitled to expect om the vast sums spent yearly on education, and is criticism applies particularly to science and such lied subjects as geography, which reaches out on ne side to history and on the other to scientific search. Though experts may differ as to the way which geography should be taught, every one will gree that small children should learn to understand d use maps, so that they can find their own way bout with confidence and help others, when ques- oned, by intelligent replies.

Nature study, so far, has had but poor results, though a host of useful books are available. One thing is evident: young children must, whenever it is possible, have the actual objects used before them. The plot of ground designed by one school for study is an excellent idea. Here "the course is recreative rather than formal, but at the same time special studies are made where accuracy is insisted on". The comment shows the survival of the view that education must be carefully dissociated from amusement. Biology for the young is not easy, and is perhaps best taken in connexion with personal hygiene. Many friends of education have long been convinced that too much is attempted in the curriculum of to-day. Thus the "Civics Course" of one school reminds us that in Russia this subject with a pronounced tinge of 'red' was forced on schoolmasters, who repudiated it and went back to teaching on the old lines. Here at least, in Mr. Wells's requirements, we are concerned with practical knowledge promoting good health and the pleasure and utility of good observation for all children. The juvenile standard of intelligence in this way in children in Great Britain is not equal to that shown by foreign children. Knowledge of other lands and ways of life is rightly emphasized. The sort of patriotism which declares that your own country is the only one which is right is out of date.

The juvenile sections of free libraries should be a great help and more useful, as implying effort, than B.B.C. talks. In general, the schemes of work printed are excellent, but a pertinent question asked is: How can the teacher find time or opportunity to keep up with all this, especially when he is confronted with the very wide method of stimulus known as 'encyclopædia work' practised in a London junior school? The observations on the junior schools note many omissions in science. Even if we agree that some of Mr. Wells's ideas are beyond young folks, some of the simpler work is disappointing; in elementary physiology, for example, questions about seeds and animals. The senior schools do not supply many records, but those given are elaborate enough to suggest the need for real refresher courses for teachers. Interest in science of some sort may be regarded as universal. Unfortunately it is not, and where teachers lack interest they are not likely to provide the stimulus which leads to permanent keenness in their pupils.

EDUCATION AND INDUSTRY

THE discussion on education as a preparation for industry which followed Dr. A. P. M. Fleming's presidential address on education for industry to Section L (Educational Science) of the British Association, delivered on August 31, was opened by a paper, read in his absence, by Mr. W. O. Lester Smith, director of education of Manchester, who stressed the importance of a sound general education and the significance of Hadow reorganization. Our educational neglect of the adolescent has led to wastage of human material. The wanton blow struck at the day continuation school clauses of the Fisher Act by the 'Geddes Axe' was probably the unkindest cut our educational system has ever suffered; it has prevented local authorities from making a satisfactory job of the youth problem.

Discussing the organization of technical education, Mr. Lester Smith referred to the value of regional co-operation and the necessity for a constant revision of the subject-matter of technical education to meet the needs of a competitive and scientific age. Although the Trades Union Congress adopted a cautious attitude to some modest suggestions in the Spens report for the infusion of technical teaching into the later stages of the secondary school curriculum, there are signs of a change in outlook. Employers are more disposed to see value in general education, and teachers are appreciating more fully the additional interest which an occupational bias can give to the last stage of school life. There is no strong evidence, however, in the post-graduate work in universities of a desire to assist industry to grapple with new problems. Industry as a career is regarded as a side-line, and industry and commerce will continue to rely mainly for its personnel, both leaders and rank and file, upon the less academic institutions and schools administered by local authorities. Finally, Mr. Lester Smith referred to the importance of facilities for training technical teachers and providing for the adequate dissemination of knowledge of new processes or of the achievements of research.

Sir Richard Gregory described opportunities open to apprentices at Portsmouth dockyard, while Dr. K. Fisher, headmaster of Oundle School, referring to the criticism of public schools that they give their pupils no chance of contact with the rest of the youth of the country, suggested that compulsory national service may remove that disability. Public schoolboys and other youths may thus become conscious of a common bond. Moreover, employers are increasingly anxious to find public schoolboys to enter their service.

The allied discussion on education in industry, which followed on September 1, was opened by Mr. J. D. Langmuir, who emphasized the responsibility and obligation of all who employ young workers to see that they have adequate practical and technica training to suit their abilities. The narrow specific workshop or office training should be provided by the employer, but the responsibility for technical training should be shared with those responsible for education There is little or no organized and systematic workshop training in Scotland, and the position of technica education is equally unsatisfactory. There has been no co-operation between education and industry, and real progress in technical education is impossible in its absence and until employers take more interest in both day-school and technical education.

After criticizing both Scottish day-school and technical education, Mr. Langmuir advocated a bolder policy of grading, which would give the pupi free choice of a course suitable for his occupationa desires. A boy with an occupational objective is more likely to remain to obtain the certificate which would facilitate entrance to his chosen career. Education should be less bookish; attempts to convert secondary schools into miniature universities resisted Supporting the idea of the junior technical school, he pleaded for closer co-operation with industry on the lines of the Edinburgh continuation class scheme He stressed the obligations of employers for technical education of young workers and the limitations of works schools, and he also discussed the possibilities of introducing day continuation classes. Before this is possible, he said, leaders of industry and commerce must recognize the importance of such education. In technical education we are far behind Belgium Denmark and Germany, and the provision of a well thought-out scheme of technical education for the rank and file of our workshops and commercial houses is long overdue.

A written communication by Mr. G. L. Darbyshire of the London Midland and Scottish Railway, which was read by Dr. Fleming, described the methods o recruitment and qualifications required for engagement by that company, as well as the training arrangements, both internal and external. In addition to classes for instruction in such special branche as block signalling, locomotive working, permanen way maintenance, etc., and lectures on special problems arranged internally, the staff are encouraged to proceed in further education. Films as well a departmental publications are used freely for instructional purposes.

Discussing part-time education outside the works Principal J. Cameron Smail, of the Heriot Wat College, Edinburgh, referred to the strain on individuals involved by part-time education in evenin classes, although the results have justified the method The outstanding results achieved with day classes i the dockyard scheme, however, have shown th possibilities of a daytime system for educated students; the psychological value of the sandwich system is also insufficiently appreciated and merits further investigation. Principal Smail referred to the danger of taking too narrow a view of technical training, to difficulties of staffing and equipment and to the importance of full contact between teachers in technical schools and current workshop and factory practice.

Dr. F. J. Chapman, of the Board of Education, stated that the most urgent educational problem before industry in Great Britain at present is the training of craftsmen. For craftsmen, as well as for technologists and managers, training involves the learning of techniques, the acquisition of skill and the study of technology. The main problem in the first is the apportionment of the training required between systematic instruction in schools on one hand and practical experience on the other; and in regard to the second, the best methods of co-operation between industry and educational institutions.

Mr. S. E. Goodall described the form of apprenticeship developed by the Metropolitan-Vickers Electrical Co. Ltd., while the concluding paper, by Prof. Willis Jackson, dealt with post-advanced education. During the past few years, provision for post-graduate practical training has been considerably extended, and on the electrical side of engineering practically every firm of note has now introduced a scheme of post-graduate apprenticeship. In exceptional circumstances only are graduates recruited direct to technical or other positions. It is now widely recognized by industrial concerns that the primary function of university courses in applied science is not to provide them with ready-made specialists, but rather to develop the ability to think deeply and critically in terms of those fundamental principles which underlie all the specialized branches of a particular applied science.

One of the advantages of the post-graduate apprenticeship system lies in the opportunity it affords for the acquisition of general engineering knowledge as well as specialized information. The ability to acquire information by such independent effort is one of the greatest assets which a man can possess, and one which our educational institutions should seek to develop. In this connexion, the recent development in local areas of post-graduate courses of instruction—termed post-advanced courses, since they also serve the needs of men who have proceeded through part-time evening courses to Higher National Certificates—of a specialized technological character appropriate to the industrial needs of those areas, is of special value. Prof. Jackson outlined certain of these courses and stressed the educational significance of the success and extension of such schemes.

WORK OF THE FORESTRY COMMISSION

IN the nineteenth annual report of the Forestry Commission for the year ending September 30, 1938 (London: H.M. Stationery Office, 1939), there are some interesting particulars on private forestry. Seven eighths of the woodlands in Great Britain, it is stated, are privately owned.

Early in 1938 the Commissioners commenced a census of all private woods, a field staff of sixteen being employed on the work. This undertaking was being carried out by trained men, data regarding area, type, age, condition, species, volume by species and girth classes of each unit of woodland being recorded. So far, 613,000 acres had been dealt with. Although the visits of Government officials on private estates are never greeted with unmixed approval, yet it may be said for this piece of bureaucratic work that the results aimed at justify the means adopted. Both in the national interests and in those of the private owner the information obtained will be invaluable. Many private owners of woodlands were aware that their property of this type was by no means yielding an adequate return; whilst a considerable percentage, through neglect and ignorant management, brought in no return whatsoever. The remission of taxation of young, properly grown woodlands which cannot in the nature of things bring in any return to the planter until they have reached a marketable value—usually a certain dimension—is understandable and mere justice. But there appears little justification to grant remission of this type on areas of poor and neglected woodland the marketable value of which is nil. From statements in this report and articles in the Press, it is evident that landowners have become alive to this problem and are endeavouring to come to an understanding upon a broad forest policy to be followed. That this is a necessary preliminary step is demonstrable. For when all is said and done, as the Continent of Europe well shows, the policy of a State forest department is not in all particulars adapted to the private owner; and is often quite impracticable for such.

The report has some interesting remarks to make upon amenity, the New Forest, and national parks, all of which have already been noted in NATURE.

The total addition to the woods of Great Britain through the operations of the Commission during the year under review was 20,300 acres, approximately 54 million trees being planted; of these, 47 per cent were Norway and Sitka spruce, 24 per cent Scots and Corsican pine, 9 per cent European and Japanese larch, 1 per cent Douglas fir and 16 per cent broad-leaved species.

The public, through the Commissioners, owned 125 forests in England and Wales and 107 forests in Scotland. The total area afforested during the nineteen years of the Commission amounts to 365,000 acres. Some of the earlier planted areas are now having the first thinnings made in them. The total area now controlled by the Forestry Commission in Great Britain amounts to 1,100,000 acres.

The year under record had some dangerously dry periods in it, commencing as early as late February in parts of Great Britain. Consequently the fire danger and damage were serious, being the worst year on record for the Commission except for 1929. The Commission attributes the damage done to railways and the general public.

SCIENCE NEWS A CENTURY AGO

G. T. Vigne's Travels in Central Asia

AT a meeting of the Asiatic Society on November 2, 1839, the director, Prof. Horace Hayman Wilson (1786–1860), introduced the traveller Godfrey Thomas Vigne (1801–63), who had recently returned home from India after a journey of seven years during which he had passed through Kashmir, Great and Little Tibet, the Punjab, Kabul and other regions, some of which had never been visited by any European, or at least had never been fully described.

After referring to the travels of the Jesuits, of Foster, Moorcroft, and Jacquemont, Prof. Wilson said, "the country north-east of Cashmere is quite new ground, and the visit of Mr. Vigne to Iskardo cannot fail to be of very great interest. His observations in that quarter will add very materially to our knowledge of the geography of that lofty region, and to that of the course of the Indus, from the frontiers of Ladakh to its issue upon the plains of India. It was to be regretted that Mr. Vigne had not been able to visit the district of Nobra and to trace the course of the Shayuk, from its confluence with the Indus to its source, but he had visited a good deal of the lower part of this northern branch, and had accurately traced the main body of the river on the west of Iskardo, to where it turns to the south, and breaks through the mountain barrier which opposes on that side. The hill States of Chambra, and others on this quarter, had also been visited for the first time; and the knowledge thus obtained had enabled us to complete the geography of the upper part of the Punjab".

Three weeks later, on November 25, Vigne gave an account of his journeyings to the Geographical Society.

Duty of Steam Engines in Cornwall

IN its issue of November 2, 1839, the *Athenæum* reviewed the "Historical Statement of Duty performed by the Steam Engines of Cornwall" compiled at the request of the British Association by Thomas Lean and Brother.

In its remarks on the statement, the *Athenæum*, after referring to the work in Cornwall of Savary, Newcomen, Smeaton and Watt, and of the improvements made, said: "Yet it is wonderful how slight is the effect which the experiments of this remote county have produced on the practice of the other parts of the mechanical world, and especially of Great Britain. While the world teems with idle projects of ridiculous 'improvements' . . . and while every one of these finds its devotee and dupe, it is truly wonderful, and most melancholy, that the simple, but very important practical truths, provisions and maxims, so well known, and so ably practised, by the Cornish steam-engineers, have made their way so slow among their fellow countrymen—truths, whereby power is obtained and economized, and fuel saved, to a greater extent, in every day's practical experience, than had been imagined possible, even by the most wild and ignorant schemer. Yet these great results have been obtained by the Cornish engineers, not from any complex or intricate mechanism—not from any patent or secret process—not from any great discovery or invention—but from the quiet and unpretending application of the best known and most common-place truths to the common steam-engine."

UNIVERSITY EVENTS

CAMBRIDGE.—E. S. Shire, of King's College, has been appointed University lecturer in physics.

B. G. Wilkinson, of Downing College, has been appointed to the Frank Smart Studentship of botany.

LEEDS.—The West Yorkshire Coal Owners' Association is renewing its donation of £1,000 a year to the Mining Department of the University for a further period of seven years.

LONDON.—The title of reader in chemistry in the University has been conferred on Dr. Fred Barrow, in respect of the post held by him at Birkbeck College.

SHEFFIELD.—Dr. A. H. Lamberton has been appointed assistant lecturer in chemistry.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT MASTER (GRADUATE IN ENGINEERING) in the Consett Secondary School and Technical Institute—The Director of Education, Shire Hall, Durham (November 8).

PSYCHOLOGIST (EDUCATIONAL AND MEDICAL) in the Child Guidance Centre and for the Mental Hospital of Sunderland County Borough—The Medical Superintendent, Cherry Knowle Hospital, Ryhope, near Sunderland (November 9).

ENGINEER SUB-LIEUTENANTS (two) in the Royal Indian Navy—The Secretary, Military Department, India Office, Whitehall, S.W.1 (quoting R.I.N. Recruitment) (November 14).

TEMPORARY FORECASTERS, GRADE II (MALE) in the Meteorological Office—The Under-Secretary of State, S.2.B.(Met.), Department Q.A., Air Ministry, Adastral House, Kingsway, W.C.2.

TEMPORARY METEOROLOGICAL ASSISTANTS (MALE) in the Meteorological Office—The Under-Secretary of State, S.2.B.(Met.), Department Q.J., Air Ministry, Adastral House, Kingsway, W.C.2.

SCIENCE MEETINGS IN WAR-TIME

WAR conditions, though they may make unprecedented demands on our scientific know-dge and technical skill, throw us, in some of their spects, back to simpler ways of living and to the se of more primitive appliances. The horse has ome into his own again; venerable carriages, earers of long-forgotten names—who, in this wentieth century generation, can readily disinguish between barouche, victoria, cabriolet and hisky?—appear in provincial streets and country ads, astonishing all but the oldest inhabitants; nd we find new merits in the performances of luly-shaded) hurricane lamps and wax candles. railway journey, prolonged after sunset, adds a ew terror to life for those of us who are not ontent to sit and think. We look back with somehing of envy to those spacious days when our randparents travelled luxuriously and read in omfort by the light of some candle-bearing conraption which could be hooked to the back of a ailway-carriage seat. Meetings, even in neutral nd reception areas, are not to be attended without ue consideration of the perils associated with a ourney through 'blacked-out' streets.

Nevertheless, it is a matter of no small imporance that our scientific societies, restricted and e-orientated as some of their activities necessarily ust be, should carry on their work to the fullest xtent possible under these new conditions of life. hasty and ill-considered cutting-down of work rings many evils in its train. Fellows tend to orget the existence of the society, and its memberhip roll falls off in consequence, the economic ife of certain sections of the community suffers nnecessary and undeserved hardships; the world t large fails to realize that a scientific society can lay as weighty a part in war as in peace. It was ever more important than it is now to conserve and to extend our mental resources; to meet and to exchange ideas; to cultivate a sane and objective outlook on the problems of a world poised insecurely on the brink of chaos.

Travel is difficult; so it was two centuries ago, and provincial towns formed, each for itself, societies for the advancement of learning. Members are scattered; and does not this very fact ensure the presence, in most of our large towns to-day, of men and women sufficiently interested in their different branches of knowledge to welcome an opportunity to exchange views and to seize an hour for the friendly discussion of intellectual problems? Cinemas may be filled to-day—and it is all to the good that they should be—even in evacuation areas; there is little room to doubt that, if the opportunity be given them, scores of scientific workers would welcome the chance to discuss the ever-changing problems of their sciences, and to find, now and again, a period of their day which would be free from the problems of war.

The past has its lessons for the present; material conditions for travel and for social intercourse were more difficult in 1770 than they are now, and we find in consequence that the greater cities of Britain tended each to cultivate a social life of its own, a social life that was dominated, in many instances, by the bearers of names now honoured in our country's history. The intellectual standard of our university towns in that age has not passed uncriticized. Gibbon has told us of Oxford; Byron, at a slightly later period, had some unkind things to say of the Cambridge fellows:

> "Where on Cam's sedgy banks supine they lie,
> Unknown, unhonoured live, unwept-for die:
> Vain as their honours, heavy as their ale,
> Sad as their wit, and tedious as their tale";

Johnson made shrewd thrusts at Scottish learning. But these are partisan views, and an impartial observer will find that the contributions of the university towns of that age to the advancement of learning and to the critical discussion of those advances were by no means unsubstantial. Other towns, as we have noted, made their contribution mainly through one or two families of dominating interests. The Taylors and Martineaus made such a group at Norwich; the Roscoes at Liverpool; and at Birmingham above all, Boulton, Watt, Small, Erasmus Darwin, Priestley and Wedgwood formed a group whose contributions to knowledge were a considerable factor in the development of eighteenth century science.

This group had, as early as the 1760's, formed the excellent habit of dining at each other's houses monthly "to exchange views relating to literature, art and science; each contributing his quota of entertainment and instruction". For the convenience of the members the meeting nights were fixed for evenings as near to that of the full moon as possible. Art had not then provided an effective means for lightening the darkness of the streets and lanes; why not make use of the illumination provided by Nature?

It is no part of our purpose to tell in detail the fortunes of the Lunar Society as it was happily named—it is sufficient to say that many discoveries of the first importance were discussed at its meetings before they were communicated in regular fashion to the Royal and to other societies; that the "learned Lunatics", as Erasmus Darwin styled his fellow-members, helped to finance much of Priestley's work; and that even when the Society, by death and dispersal, had lost most of its members and was moribund, Leonard Horner could say of it, in 1809, that "the remnant of the Lunar Society and the fresh remembrance in others of the remarkable men who composed it are very interesting. The impression which they made is not yet worn out, but shows itself, to the second and third generation, in a spirit of scientifi curiosity and free inquiry which even yet makes some stand against the combined forces of Methodism, Toryism and love of gain."

The spirit of free inquiry has to-day to encounter forces other than those which excited the concern of Horner, and the learned societies of th democratic countries—indeed, of all countries—may even to-day learn something from the zea and unselfishness which informed the work of th Lunar Society. In one small matter they migh very well profit by the return to some of th conditions of life as it was lived in the days of Erasmus Darwin, and hold meetings on nights nea the date of the full moon. If secretaries of th learned societies of London were to consult thei almanacs and maps of Britain, they would surely find times and places favourable for the holdin of informal meetings suited to present-day needs as the Linnean Society is already doing (see pag 778); and the Lunar Society would enter on a new lease of life.

NATURAL AND POLITICAL PHILOSOPHIES

Science and Politics in the Ancient World
By Prof. Benjamin Farrington. Pp. 244. (London: George Allen and Unwin, Ltd., 1939.) 10*s*. 6*d*. net.

IN Plato's City-State, the ruler or lawgivers were held to be justified in inventing or approving useful or pious lies if the best minds were convinced that the community was incapable of understanding the truth. The State had to decide what was good for the people to know and accept, whether relating to governmental legislation or religious beliefs. The right appreciation of truth was regarded as the prerogative of a select few and, as popular intelligence was not prepared for enlightenment, it was inexpedient to teach the masses anything which would disturb either their social complacency or superstitions. Socrates himself, to whom many of the political principles represented in Plato's "Republic" can be ascribed was condemned to die because he would not cease to "corrupt the young" by his teaching; and Galileo might have saved himself from imprisonment by ceasing to disturb the traditional teaching of the Church as to the stability of the earth in the centre of the universe.

It is with repercussions of this kind in the ancient worlds of Greece and Rome that Prof Farrington is concerned in his critical survey of philosophies of science in relation to political action from the period of Thales and Anaximander in the sixth century B.C., through Empedocles Leucippus and Democritus, creators of theories of atomism, which, with Hippocratic medicine, are the two great achievements of pre-Socratic science, to Plato, Epicurus, Lucretius and some theological philosophers of the Christian era. Beginning with appreciative references to the brilliant work of the early philosophers of the Ionian school, who may be said to have founded physical science, Prof. Farrington traces the decline of the spirit of inquiry into the nature of things and attributes it largely to the influence of Platonism. They made few actual experiments, but they understood the difference between theory based upon observations of natural phenomena and metaphysical speculations. Had their spirit not been suppressed because it was not believed to be expedient to politics or religion that the people should partake of the new knowledge, there is no doubt that, within the limits of observation available, experimental philosophy would have made great advances in the ancient world.

The view of the Governments and leaders of thought in the class-divided societies of classical antiquity was that the mass of the people should be guided only with knowledge which was considered to be "wholesome" for the good of the State, and that it was therefore permissible to maintain control through the use of the "Golden Lie". There are many to-day who see in modern science nothing but a disturbing influence which threatens the destruction of all that is worth preserving in civilized life, and regret that its progress has not been strictly impeded. The purpose of suppression of ideas in the ancient world was to secure the stability of a slave State; and the social problems raised by the increase of power by machines and in weapons of war had not arisen. Whatever the consequences, Prof. Farrington maintains that, with the actual progress of knowledge, modern society is unworkable without a wide understanding of the results. He remarks:

> "These considerations reveal to us the further fact that there is a connection between the character of science and its dissemination. In this matter our democracies are at the cross-roads. Either our science must transform itself by the recognition that the history of its development is unintelligible without an understanding of its social origin, that men cannot be adequately trained in applied science without instruction in its social functions; and that the obstacles to the progress of science can be external to it, in the sense that they rise out of the structure of society as well as out of theoretical errors; either this transformation must take place or science must retreat. The future of science is now plainly a political question. Either we must base our civilization more thoroughly on scientific foundations, or we must destroy science itself. Both processes are taking place in the world to-day."

Nearly one half of Prof. Farrington's book is devoted to the social and political, as well as the scientific, implications of the works of the two great classical writers, Epicurus and Lucretius, who carried on the traditions of Ionian natural philosophy, and helped to free the minds of men from the fetters of superstition. In his support of the Ionian tradition, and his advocacy of popular enlightenment, Epicurus was fundamentally opposed to the philosophy of Plato He identified philosophy with a knowledge of Nature, and laid emphasis on sense evidence as the criterion of truth. It was Epicurus who endowed the atom with an element of spontaneity of movement, or "swerve", and he connected this with the idea of the freedom of will in man. He did not invent the theory of atomism, with the precise development of which the name of Democritus, who lived a century earlier, is now rightly associated, but to him must be ascribed the introduction of the element of intrinsic movement, as, for example. in the jump of an electron from one orbit to another, which modern atomic theory has to take into account.

The opposition to Epicurus and his disciples did not arise from these scientific aspects of atomism, but from teaching which would deprive religion of its value as an instrument of political domination. To the Epicurean, the history of man and civilization was part of the natural history of the universe; and it was the specific originality of Epicurus to have defended freedom of the will in man as a product of evolution. Lucretius presented this philosophy with passionate intensity in his "De Rerum Natura". His poem was a protest against the use of superstitious beliefs for political authority and a plea for the rational study of natural events and phenomena. It represented "the last great cry of Greek science, expressing not only its devotion to truth but its devotion to humanity"; and because it was as contrary to the political system of the rulers of Rome as it was unacceptable to the oligarchies of earlier Greece, the Epicurean philosophers were expelled by the Roman Senate in the year 173 B.C. With the birth of Christianity, another element for the regeneration of ancient society came into existence, but physical science had no place in it, and suppression of all knowledge of Nature except that derived from the Hebrew Scriptures prevailed for a thousand years.

Prof. Farrington's scholarly and original survey of the reactions between natural science, religious beliefs and political power is of particular interest at the present time when civilization is in the melting-pot, with these three elements as the main constituents of a compound which, whatever its nature, will have a determining influence upon human evolution for many generations. The social relationships which he submits to critical analysis are those of City-States, but the crucible into which they have now been thrown is that of the world, and all who believe in truth and righteousness as standards of value should contribute whatever is within their power to make the fiery proces through which we are now passing a means o constructing a world organization of society worth of the intelligence of twentieth century civilization.

R. A. Gregory.

ANIMAL PHYSIOLOGY

An Introduction to Animal Physiology
By W. B. Yapp. Pp. xv + 320 + 4 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1939.) 8s. 6d. net.

THE quotation from "Through the Looking Glass" which precedes the text of this book gives the clue to its contents.

> "Come, tell me how you live," I cried,
> "And what it is you do."

The author, assuming a knowledge of animal morphology and organic chemistry on the part of the reader, uses these as the basis for the more mechanistic side of comparative physiology, and this in its turn serves to explain the working of the animal body as a whole, its reactions to the outside world, the co-ordination of its vital processes, and its adjustments to the environment in so far as these can be considered from a mechanistic point of view. There are chapters on nutrition, excretion, respiration, effector systems and reproduction, dealing with the working of isolated tissues and organs, and on co-ordination, behaviour and regulation, describing the reactions of the animal as an individual. Each chapter is subdivided on the lines of the Dewey system, so that a subject can be traced either from the index or from the table of contents. This is important, since one chapter may range over the whole animal kingdom and all parts of the animal body. Thus Chapter iv, the effector systems, contains an account of the working of cilia and flagella, pseudopodia, muscles, glands, electric organs, luminescent organs, nematocysts and chromatophores.

All who are concerned with zoological work will welcome the appearance of this book. There is no doubt that it will satisfy a need, both in the schools where biology is taught and in the universities. Its subject-matter is sound and well chosen, and the author has made careful use of the current literature. It is a thoroughly competent piece of work. The criticisms which follow are mostly of a minor character and in no way minimize the value of the book as a whole.

So much material has been incorporated into th book that much of it might consist of lecture notes and it lacks the literary style that makes a boo readable. The first chapter suffers most from thi defect, but in later chapters there is considerabl improvement, as though the author had got int his stride. The subject-matter in the chapter o nutrition is illogically arranged and sometime obscurely expressed. For example, the *physica* side of the process of digestion is neglected unt the whole of the *chemical* reactions have bee dealt with, and after the digestion of protein fats and carbohydrates has been described, an the digested matter has been absorbed throug the walls of the villi, the reader comes to a sectio which begins, "In man and many other mammal the food in the mouth is masticated". Since thi physical breakdown of the food is preparatory t any chemical action, why should not this sectio (1.315) have preceded the other? Moreover, b placing it first, the reader is reminded of the cour of the alimentary canal as a whole, and is bette prepared to understand the chemical section where morphological sequence cannot be followed

Some of the statements are misleading. "I man about a litre of saliva is produced a day. I contains a protein called mucin, and its chief valu is to act as a lubricant". There is no mention o ptyalin in this section (1.31) although the enzyme of the stomach are recorded. Again, "One . . . i called a male or a spermatozoon, and the other . . a female or an ovum" (p. 252). "The vertebrat kidney . eliminates water, nitrogen and man other substances". Such sentences require more accurate presentation of the facts.

So much subject-matter has been utilized tha one hesitates to name omissions. But since mos university students dissect the nerves supplyin the taste buds of the teleost fish, the brief statement on p 209 might be expanded, and Herrick' paper on the gustatory organs of fishes added t the list of references. The inferiority of the sens of smell in man (p. 211) is both physiologic and morphological, yet no use is made of th latter contribution, although sniffing in order t lift the odorous particles above the naso- an maxillo-turbinals (innervated by the trigeminal nerve) to the pocket in which lie the ethmo-turbinals (innervated by the olfactory nerve) is an adaptation which explains the statement that the sense of smell in man is very poor compared with that in dogs and many other animals. Graham's paper on the crystalline style (*Proc. Zool. Soc.*, 109, 1; 1939) probably appeared too late for inclusion, but why is Russell's work on behaviour not mentioned? Also Parson's "Biochemistry" is an almost indispensable companion volume.

The book has been well produced by the Oxford University Press and there are few misprints. Schäfer's name is wrongly spelt on both occasions when it is mentioned, *inhalant* should be replaced by *exhalant* on p. 9, line 17, and Henle has no accent on the final e. There are four plates and forty text-figures, most of which are copied from other authors. Figs. 4 and 40 are poor and inaccurate.

On the whole, however, the book is an admirable effort in a new and rapidly expanding field of biology. We hope the author will now produce a volume of practical exercises in animal physiology.

RACE QUESTIONS IN EUROPE

(1) The Races of Europe

By Prof. Carleton Stevens Coon. Pp. xvi + 739 + 16 plates. (New York: The Macmillan Company, 1939.) 31*s.* 6*d.* net.

(2) The Races of Central Europe

A Footnote to History. By Dr. G. M. Morant. Pp. 164. (London: George Allen and Unwin, Ltd., 1939.) 5*s.* net.

1) IN 1899 W. Z. Ripley produced his classic work on "Races of Europe" and the appearance of a book prepared at his suggestion to bring matters up to date is of considerable importance, especially in these days when race-study is suffering so severely from political perversions. Coon has read very widely and tries to bring together data from archæology and physical anthropology; his syntheses are often bold but always suggestive, and he indicates in several places that evidence on particular points is specially defective.

Coon's broad conclusion is that the present-day biological types in Europe are derived from: (1) a basic *Homo sapiens* related to the remote ancestors of the Mediterranean types; (2) a blend of (1) with some *non-sapiens* form of general Neanderthaloid form; (3) various blends of (1) and (2), all being present and widely distributed in Europe while collecting, hunting and fishing were still the only means of getting food; (4) peoples from Asia and North Africa of Mediterranean types who introduced the arts of food production.

To Group 1 the author considers we should ascribe the Galley Hill skull which he accepts as Middle Pleistocene, the so-called Negroids of Grimaldi, and the male skeleton from the Upper Palæolithic of Combe Capelle, France. They are short, long- and very narrow-headed with a high cranial vault, moderate cheek bones and lower jaws, fairly wide nose and little projection of the mouth. To Group 2 he ascribes the Cro Magnon man and the Solutré skulls among western and west central European types and notes the tallness, the greater width of the head than in Group 1 and the very broad facial development with low orbits and narrow noses. The east-central European variety is again tall and bony but is extremely long-headed like Group 1.

Once he had adapted himself to the cold, in the second phase of the Würm glaciation, man followed the retreat of the ice northwards and there thus came into existence the basic elements of population in north-west Europe, the east-central variety of Group 2 being increasing'y important. Coon looks upon the west-central variety of Group 2 as the root stock of later central European broadheads, but thinks there may be factors other than Mendelian dominance connected with the remarkable spread of broadheadedness, now almost universal in central Europe; the mean cephalic indexes he gives for different parts of Germany range from 80 to 85.

Coon notes the zoning of pigmentation from blondness in the north-west to predominant dark colouring of head and eyes in the south and south-east. For him, as for most unprejudiced students, there is not a blond long-headed tall type distinct from the beginning of the story. The spread of the arts of food production and of settled life he sees as an accompaniment of the advance of the Mediterranean types into Europe, sometimes handing on their knowledge to descendants of the varieties of Group 2. He thinks the early Danubian peasantry were of Mediterranean type and that the people who made corded pottery, and were of the east-central variety of Group 2, blended with survivors of Palæolithic men who had followed the retreating ice, and that this mixture, with loss of pigmentation, became what is known as the Nordic group. But this summarizes his account too severely, and students should read his pages, realizing, as he does, that his synthesis may well be modified very greatly as knowledge grows. The one thing that appears ever more clearly is that civilization did not originate in the Germanic-West Baltic area as some have tried to argue.

Coon looks upon the Lapps as to some extent early European broadheads related to the west-central variety of Group 2, modified by immigrants from Asia along the north. Another interesting hypothesis is that the people with flat-backed high broad heads, commonly called Dinaric, are the result of a blend between a tall variety of the Mediterranean group and the early broad-heads of Central Europe. He shows that Alpine or Central European, as well as north-west European elements, have entered to a large extent into the composition of the modern Jewish groups, which vary greatly from place to place and in any one place include very diverse individuals. The basis, like that of the European population, is Mediterranean. One welcomes the wisdom of the author in avoiding assertions about racial superiority or inferiority and in insisting on the importance of past blending and intermixture in the racial history of Europe.

In a second edition one hopes the author will include some discussion of the Milankovitch chronology, will perhaps be a little more critical here and there on the physiological side, will clear up a few expressions and printer's errors and slips of memory such as one on p. 375 which mixes refugees after the revocation of the Edict of Nantes (1685) with those who fled from the atrocities of the Duke of Alva (1567–73), and penslips such as one on p. 372 which says the Irish Goidels invaded Scotland from the east.

The fifty plates, mostly with twelve photographs on each, usually giving full face, profile and semi-profile views of persons whose measurements are also given, set a high standard, especially as explanatory text accompanies the photographs and often summarizes clearly the arguments in the body of the book.

(2) Dr. G. Morant's little study of "The Races of Central Europe" is essentially a tract for the times and is a careful exposition of his point of view backed by a mass of information concerning details, and very ably put together. Dr. Morant represents the older biometric school of anthropologists which holds that it is best to deal with samples of populations as units and to describe them by means of average values for the different physical characters; those who feel the weakness of this mode of approach are anxious to pay their tribute to the ability and sincerity of Dr. Morant's work.

Both Coon and Morant in their diverse ways emphasize that greater differences can be found between German-speaking groups in Central Europe than those between certain German and certain non-German peoples, and Morant has worked this out for blood-agglutination figures as well. The proportion of O and the ratio of A to B vary together to a large extent, a high proportion of O being accompanied by a high ratio of A to B Both these figures are far higher for samples from the pre-Munich Germany than for samples from lands to the east. East Prussian, Silesian and Austrian samples are characteristically intermediate between the non-strictly German ones and those for Polish, Czech, Slovak, Magyar or Rumanian areas, while such information as we have for Russia shows still smaller values for O and for A/B.

Morant considers that in the *Völkerwanderungszeit*, the German peoples were longheaded (indexes 72–76), that in the Merovingian time there was a great infiltration of broad heads (indexes above 80) in two main waves. These two waves completely swamped the earlier type which disappeared There is a considerable measure of truth in this statement, but it is well to remember, as Morant does, that the number of skulls available is not large and may represent a selected, perhaps an aristocratic, group. Morant emphasizes that, for Central Europe, cephalic index, colouring and stature are less important criteria than blood agglutination groups, and the latter have the advantage that they appear to remain constant throughout life, while samples of males and females respectively in the same district correspond closely. Also, here we have to do with distinctive characters, not with measurements and ratios that shade into one another.

Concerning utilization of averages and the difficulties involved, we note that Morant gives (Fig. 3) the marking to Bohemia and Moravia that indicates an average stature of 168–170 cm., as against 166–168 cm. in Bavaria and Austria, etc., and 164–166 cm. in Germany. Coon, on the other hand, gives 167 cm. as the average Czech stature Differences of sample can affect the result and in this case the acceptance of Coon's figure would put the Czechs into the same grade as the Austrians and Bavarians. Quite possibly Morant's statement is nearer the truth, but averages are of doubtful value.

Morant is clear that race cannot be used to rearrange the political map of Europe and that racialism as between Europeans is rubbish. All his fellow-workers will subscribe to this conclusion whatever reserves—and they are many—they have about his utilization of Pearson's coefficient of racial likeness. He sees that it is only a rough instrument of analysis; many others feel it has led to such errors as should put it out of court.

THE ELECTRIC DISCHARGE IN ENGINEERING SCIENCE

Gaseous Electrical Conductors
y Prof. E. L. E. Wheatcroft. (Oxford Engineering
cience Series.) Pp. xi+265+6 plates. (Oxford :
larendon Press ; London : Oxford University
ress, 1938.) 21*s.* net.

THE earliest industrial applications of the phenomena associated with strongly ionized ases, or 'gaseous conductors', appear to have een the introduction in England of the carbon rc for illumination in the early eighties, followed hortly by Moore's nitrogen and carbon dioxide ischarge tubes in America. In the beginning of e twentieth century, electric discharges first egan to be used on a considerable scale in chemical ngineering, notably for the production of ozone connexion with air and water purification, of tric acid from the air, and of lubricants by the lymerization of light oils ; about the same me discharges were also applied to the precipi-tion of dust and mist, and to the generation of igh-frequency currents for radio communication. he phenomena associated with 'free' electrons in igh vacua have been applied in the development the present rich variety of X-ray tubes, wireless alves, and cathode ray tubes. The development the transmission of electric energy has brought light the importance of discharge phenomena relation to the design of high-tension cables, sulators, condensers, and switchgear ; and the hysics and chemistry of the ionosphere are rectly related to many problems of radio com-unication. Not the least important is the ignition stem of all petrol-fed internal combustion engines, hich depends on a gaseous electric discharge.

The comprehensive title, and the preface of rof. Wheatcroft's book, which is the latest ddition to a distinguished series, lead the reader expect it to be the first English book dealing ith gaseous discharge phenomena in relation to e rapidly growing applications in many branches engineering ; the author explains that his aim expanding his lectures to undergraduates is to roduce a book that will be useful to those who embark upon research in this very interesting d important field". The book is in two parts : e first deals with the physical background ; the cond relates to applications, but of these the ly ones considered are thermionic valves ('hard' d 'soft'), the mercury arc rectifier, circuit reakers, and discharge tubes as illuminants.

In giving the physical background in Part 1, e emphasis has not been fairly divided between ure' electron gas as a conductor, and electron gas admixed with ion and neutral molecular or atomic gas, the former being allotted much the greater space ; and a whole chapter is devoted to electrons *in* metals. For example, the motion of electrons in a 'dense' gas is dismissed in three pages with a few equations and without any reference to the experimental data of Townsend and others ; the result is that the uninitiated reader would gain a totally false sense of simplicity and never realize the essential complexity of the phenomena. Townsend's coefficient of ionization is needlessly and erroneously renamed "the ionization constant α". Also, there is no point in giving Townsend's early theory of this coefficient without indicating the unjustifiable assumptions now known to be involved in it, or to offer an alternative makeshift theory without referring to the detailed analyses of the problem which have been given both for atomic and molecular gases.

Part 2 opens with a long chapter on "Vacuum Electron Valves", which, however, contains much that is irrelevant to this book ; for example, the discussion of high-vacuum valve design. The three following chapters on gas-filled valves, the mercury arc rectifier, and circuit breakers, are good, profusely illustrated, and bespeak an intimate acquaintance with these applications. It is this part of the book that the reader who seeks succinct but adequate information will find most useful. The last chapter, on luminous discharge tubes, is startingly inadequate to a branch of gas discharge engineering which is of ever-increasing importance.

The attempt to introduce further complication and changes of convention in the nomenclature for units is to be deplored ; for example, the electromagnetic unit of potential is termed the 'centimicrovolt', and engineers have long since decided that the microfarad is a more convenient and practical unit than the farad.

The presentation of the material in this book reflects too often those digressions which are illuminating in a lecture but distracting in a book. Despite the collation of much useful information, and the beautiful production to which we are accustomed from the Oxford University Press, the book falls short of the high standard set by the rest of the series. Nevertheless, for the reader who is willing to spend the time disentangling the information he requires (the joint author-subject index is too brief to be very helpful), there is much in this book which is worthy of attention.

L. S. Harley.
R. Winstanley Lunt.

THE PROBLEM OF PAIN

By Prof. P. T. Herring,
University of St. Andrews

At the Dundee meeting last September of the British Association, Section I (Physiology) paid a visit to St. Andrews, where a discussion was held in the Physiology Department of the University on the problem of pain.

The physiology of pain, interesting and important though it is, is still unsolved. Pain must be regarded as a physiological sensation of a protective character; but like many other physiological phenomena it can become pathological, and the boundary between the two is indefinable. We have no means of determining the intensity of pain, and the psychological element is often an important factor. Many different kinds of pain are described, some of which are due to the admixture of other sensations in consciousness.

For the production of sensation certain anatomical structures are essential—receptors, afferent nerve fibres and a nerve centre or centres which translate the impulses into a conscious sensation. Not all the receptors capable of receiving pain-producing stimuli are known; but the more highly specialized nerve endings can be dismissed, for modern work has shown that they are adapted to specific stimuli only. The cornea of the eye provides an example of a structure which is supposed to be capable of receiving no other sensation than that of pain, and in the cornea the nerve endings are naked axis cylinder terminations intimately associated with the epithelial cells which cover it. The receptors in the epidermis of the skin are believed to be of the same nature, but lying more deeply placed in the living epithelium. In the connective tissues of the true skin there are also many endings of the same kind. The skin is the protective covering of the body, and any form of stimulus which injures it is an adequate one for the production of pain.

There is a pattern of so-called pain spots in the epidermis, and by the use of a finely pointed needle it may be shown that the skin varies in the amount of pain produced by a strictly localized injury. It is not known how the nerve terminations are stimulated to discharge nerve impulses. Nerve fibres are relatively resistant to mechanical stimulation, and it is not improbable that it is the living epithelial cells which respond to injury with the production of some chemical substance which provides the adequate stimulus. The persistence of the sensation of pain after injury favours the view that a chemical agent is the exciting factor.

There is even less satisfactory evidence as t the nature of the afferent fibres which convey t impulses to the central nervous system. There a at least two possibilities. According to Müller law of the specific irritability of nerve, the should be special fibres for the conveyance of t impulses that give rise to pain. Some observe have claimed the existence of special pain fibre Ranson states that they are small in diameter a non-medullated. They may belong to Erlang and Gasser's *C* group; but these have a slo conduction rate, and, as Adrian points out, it scarcely likely that pain—a danger signal—dependent solely upon slowly conducting fibre It is more probable that fibres of this descripti are concerned with the conveyance of pain fro the viscera, but not from the outer covering the body where the more rapid the response t better the protection afforded. The other pos bility is that pain-producing nerve impulses a carried by nerve fibres which are normally co cerned in the production of other effects, and th a more rapid series of impulses, or a greater ma effect, floods the central nervous system and ove flows into tracts which convey pain-produci nerve impulses from more sensitive areas. T work of Adrian and others is on the whole oppos to this theory, and the trend of physiologic opinion is at present in favour of the existence specific pain fibres.

In the production of visceral pain, the utilizati of nerve fibres ordinarily concerned in reflex acti unaccompanied by conscious sensation is perha more likely, for it seems unreasonable to postula the existence of special receptors and nerve fibr in organs which for many generations of individu are never called into use.

However conveyed, all pain impulses appear enter the central nervous system in Hughlin Jackson's lower level. In man a second neuro arises in the grey matter of the same side, d cussates and runs upwards in the antero-later columns. Cases of syringomyelia support the vi that in man there are special fibres in the spin cord associated with the conduction of pa impulses. The fibres must make numerous co nexions, for severe pain excites reflexes involvi cardiac, respiratory and other vital physiologi processes.

Afferent nuclei in the optic thalamus appear be the basal receiving centres, and these in tu nsmit certain of the impulses to the grey matter the cortex. There is reason to believe that pulses reaching the optic thalamus give rise to in, but that the sensation produced there differs some respects from that perceived by the cortex ebri, the pain being more diffuse, less well alized and of a peculiar character. Pain felt the thalamus has some of the characteristics of otopathic sensibility. Head's classification of dy sensation into protopathic and epicritic has en much debated. There is no doubt the stinction exists; but its exact significance nains to be determined.

The physiology of pain in structures that lie per than the protective covering of the body sents further problems. Many tissues and organs the body are capable of pain, but the adequate mulus is often a specific one, and the injuries ich produce pain in the skin or parietes fail to duce any sensation whatever in many of the cera. Muscle, whether skeletal, cardiac or ceral, can be cut, burnt or otherwise injured hout the production of sensation. Yet pain, d pain of a very severe character, can be exienced by muscle. The adequate stimulus is w believed to be tension, and particularly tension the absence of an efficient circulation. Sir omas Lewis, from experimental evidence, beves that muscle under these conditions liberates ne metabolic substance which diffuses rapidly d affects the sensory nerve terminations tside the actual muscle fibres. The nature the pain-producing substance, factor *P*, is known.

The capability of experience of pain by the cera may to some extent depend upon the sence in or around them of connective tissue aths. Peritoneal, pleural and other memaneous coverings carry their own nerve supplies, d these may be important factors in the reception d localization of pain. Pain from the viscera commonly referred, not to the organ in question, t to some area of the body surface endowed th higher sensibility, and is then known as ferred' pain. Prof. Waterston suggests that pain this nature should be called 'heterotopic' to tinguish it from 'homoiotopic', or pain referred its actual site of origin.

Ross was one of the first to attempt an explanan of visceral pain. He described two types, erred pain and true visceral or splanchnic pain. ckenzie, impressed by his own observations on insensitivity of the viscera, elaborated Ross's ory of the radiation of pain from the viscera the parietes through an irritable focus in the nal cord, but denied the existence of true ceral pain. Mackenzie believed that pain ociated with a diseased viscus is never felt in that organ, but is always referred to an area of higher sensibility in the body wall. The pain may be extremely severe, and accompanied by reflexes, local and general. The local manifestations are of great value to the clinician in that they give him information as to the site and extent of the disturbance. The details of the work of Ross and Mackenzie have been much debated. Prof. Morley, who spoke at the meeting, considers that Mackenzie failed to appreciate the difference between referred pain from the parietal peritoneum and that from an intraperitoneal viscus. Morley believes that referred pain arises from the irritation of nerves sensitive to those stimuli which produce pain when applied to the surface of the body. He considers that pain from the urinary system, which is retroperitoneal, harmonizes with Mackenzie's view, though gastro-intestinal pain does not. The difficulty arises because of the complication introduced by the presence to a varying extent in the abdominal viscera of peritoneum and mesentery, structures carrying their own nerve supplies, and differing in their sensitivity.

Mackenzie believed that excessive contraction of muscle is the cause of pain in whatever viscus it is found. Colic and the pain of hunger may be cited as examples. Payne and Poulton, in a series of careful experiments, came to the conclusion that visceral pain from muscle is caused, not by its contraction directly, but by tension, and that the stimulus is a stretching and deformity of pain endings in the wall of the stretched viscus. The frequent association of pain with contraction is explainable on the assumption that excessive tension is put upon the tissues with which the contracted fibres are in continuity.

Headache presents another interesting problem. Apart from local conditions, such as neuralgia affecting the scalp, and vascular spasm in the tegumentary covering, headache is often a referred pain, and its source some part of the alimentary tract. The afferent nerves are those of the visceral fibres of the vagus, and the pain is referred to areas supplied by the trigeminal nerve. Some disturbance in the abdomen gives rise to pain which is felt as a headache. When the pain is of intracranial origin, its cause is now commonly ascribed to vascular changes in the pia-arachnoid membrane of the brain. The intravenous injection of histamine sets up severe headache. Histamine is a powerful vasodilator, and congestion of the blood vessels induced by its action is thought to be the cause of the pain. Withdrawal of cerebrospinal fluid by lumbar puncture has much the same effect by decreasing the intracranial pressure. The receptors are apparently in the pia-arachnoid membrane, but may also be present in the choroid plexuses.

Even more interesting than pain is the problem of its relief. Intractable pain is fortunately rare but does occur in some diseases. Opium and its derivatives, though of great value, are not altogether satisfactory, especially when the pain is lasting; and they have other drawbacks. Section of afferent nerves, extirpation of ganglia and other destructive procedures, have been used in intractable pain. All such methods are attempts to prevent the passage of pain-producing impulses by t afferent nerves to the central nervous syste Mr. Todd described a method of alleviation b the intrathecal injection of alcohol. This paralys the afferent fibres in the spinal canal, and h proved valuable in cases suffering from pa in the pelvis and lower limbs. There is st room for some drug which will possess the ide properties.

METAMORPHISM AND IGNEOUS ACTION*

By Prof. H. H. Read, F.R.S.,

Imperial College of Science and Technology, London

APART from the question of the time-continuity of the progressive series represented by, say, the Barrovian zones, there is the chemical continuity to be considered. How far do the zones of Barrow represent an isochemical series of pelitic rocks? The degree to which such processes as metamorphic differentiation and diffusion have operated obviously affects the compositions of members of the series at any stage. Such possible departures from the isochemical series arise through processes inherent in the rock. There is, however, another aspect of this topic which, though usually ignored in Great Britain, must in my opinion be carefully considered. The possibility of the introduction of material of so-called magmatic origin is one that certainly cannot be dismissed in the higher grades, and one that might apply even to the lower grades of regional metamorphism. It will be convenient for the development of my argument, however, if we transfer ourselves to the domain of ultrametamorphism, and I discuss the reality of granitization, for, if granitization is real, certain consequences seem to follow.

In a paper which has appeared during the writing of this address, granitization is defined by Malcolm MacGregor and Gilbert Wilson as "the process by which solid rocks are converted to rocks of granitic character". It includes all such operations as palingenesis, syntexis, transfusion, permeation, metasomatism, migmatization, injection, assimilation, contamination, and the like. These authors conclude that exchanges take place between the country-rocks and their pore-fluids—whether these are entirely indigenous or reinforced by accessions from magmatic sources—and that these exchanges are selective so that there is a convergence, both chemical and mineralogical, of rocks originally different. They consider two processes to be concerned in granitization; first, a metasomatism under the influence of "perme ing highly energized fluids—emanations—ahead advancing magma", and second, a mechani penetration by magma. I consider that no reaso able objection can be raised to these conclusio notwithstanding the uncompromising attitude Rosenbusch and others.

The question of room in migmatization is o that has caused difficulties to many observe This room-question was answered by Hugh Mil fifty years ago, and has been answered many tim since. Replacement is the essential process in t formation of the migmatites. It is unfortuna that the term injection-complex, used in Gre Britain, emphasizes injection, since permeatic imbibition and metasomatism are more wid spread phenomena. As I have pointed out el where, the formation of banded gneisses and li par-lit complexes is best explained by a process replacement to different degrees along layers different permeabilities. The many examples the tracing of the regional country-rock structu through granitic masses, the existence of th plane screens of country-rock in them, the gre extension of minute *lits* of quartzo-felspath material in migmatites, and the detailed heter geneity of many granites are all readily explicab by a replacement origin for these rocks.

Replacement in sedimentary rocks will be co trolled by the original structures of such rock Permeation by the emanations or ichors will ta place preferentially along certain layers dependi upon both the chemical and physical nature these layers. Original platy minerals lying in th bedding planes will become enlarged if they su the new chemical environment, and new-form minerals will grow so that their direction greatest crystallization-velocity agrees with th old planes of weakness. The original sedimenta structure may thus become preserved until a hi

---

*Continued from page 731.

degree of granitization has been reached, and the bulk composition of the rock has been greatly changed. I consider the foliation of granitic gneisses, for example, as essentially controlled by previously existing sedimentary structures, and not by any process of dynamic metamorphism or piezo-crystallization.

Whether the granitizing solutions are thought of as emanations of no specified ancestry, or as ichors from a granitic magma-body, opinion is agreed amongst workers in this subject that they are highly mobile and capable of great chemical action. Working in conjunction with the pore-fluids of the country-rock, they can transform vast portions of the crust. In connexion with direct granitic invasion, gases may be of great importance; when they have condensed to solutions and have received assistance from the true liquid residuals and from the pore-solutions, they must be capable of gigantic results. I wish to emphasize, therefore, that granitization and felspathization are valid processes, and that they are essentially based upon replacement.

In regions of granitization there has been an afflux of material, either from a 'magmatic' body or from some unspecified source. It is reasonable to believe that during the resulting replacement there occurs an emigration of material. Holmes has put the whole matter graphically—"the 'granite' is the balance of what was there originally, *plus* what has migrated in, *minus* what has been driven out". The emigrating material moves into the country-rocks adjacent to the theatre of granitization.

The material thus moving through the country-rocks is of several origins and qualities. It consists of (i) the material expelled from the region of granitization; (ii) the direct emanations from the granitizing agent; and (iii) the pore-fluids of the country-rocks. Its diverse constituents must move with different speeds, perhaps depending, as Backlund has ingeniously suggested, upon the ionic radii of the participating elements. Various overlapping belts of precipitation may come into being, and from each a further expulsion may take place. By some such processes zones of various characters arise about the granitization or migmatite core.

Wegmann has elaborated a magnesia-metasomatism dependent upon the expulsion mechanism in granitization; he expects to find a zone characterized by cordierite in close proximity to the migmatite area, whilst farther away would be found lower-temperature minerals like andalusite, kyanite, garnet, etc., and farther still tourmaline. The formation of 'fronts' of more or less marked chemical individuality can be exemplified by the soda-fronts of Stavanger, Sutherland, and Cromar, Aberdeenshire, by the potash-front of Hango, Finland, and by the magnesia-front of Orijärvi; there is no need to elaborate these examples.

One of the most firmly established facts of metamorphic geology is the close association in the field of highest grade metamorphic rocks and migmatites. The significance of this coincidence has been differently interpreted. I adopt the view of the company familiar with migmatites and see with them a direct causal relation between the highest grade of regional metamorphism and migmatization.

In my opinion, therefore, the cordierite and sillimanite zones are genetically related to granitization. But these zones are the final stages of the apparently continuous progressive series of Barrovian zones which as a whole supply the common types of regionally metamorphosed rocks. It seems reasonable to me, therefore, to believe that regional metamorphism as a whole is genetically related to 'igneous' activity of some kind.

Out from the central theatre of granitization there pass waves of metasomatizing solutions, changing in composition and in temperature as they become more distant from the core and promoting thereby the formation of zones of metamorphism about it. Very often a spurious depth control appears to have operated, since the flow of solutions must be largely towards higher parts of the crust. Such a metasomatic metamorphism accounts for the superposition occasionally observed of high-grade zones on lower-grade, and does away with the infelicities attending the alleged inversion of metamorphic zones. Further, the difficulties that the idea of static or load metamorphism fails to meet are surmounted. Deeply buried sediments remain unmetamorphosed unless igneous material gets access to them. In metasomatic metamorphism, original sedimentary textures can be reasonably preserved, mimetic crystallization can prevail, schistosity and bedding, even in violently folded strata, can coincide. Finally, all those phenomena which Daly felt to be "truly inexplicable by pure dynamic metamorphism", are satisfactorily explained.

A continuous series of changes in composition from low-grade regionally metamorphosed rocks to migmatites has been established by many investigations. Even in the low-grade rocks changes are perceptible, and all must be ascribed to the activity of material from a granitizatio centre. To move this material and to promot the recrystallizations and replacements t ocu in cubic miles of rock, great quantities o are required. It seems to me unlikely solvents in action are indigenous to the rocks—*they* are more reasonably to be from a granitic source. When the en extent of migmatite granites is considered, it is clear that sufficient water is available to promote the changes seen in the regionally metamorphosed rocks.

Are there any indications in low- to medium-grade rocks, not visibly associated with igneous activity in the field, which point to solutions from magmatic sources having travelled so far from the locus of migmatization? In my opinion, we see such indications in the presence of tourmaline in rocks of all grades. Admittedly, this opinion is one not generally accepted in Great Britain, but on balance I prefer to regard most tourmaline in metamorphic rocks as due to impregnations from granitization fluids. Tourmaline occurs not only in pelitic derivatives but also in rocks of other compositions. In many examples of high- and medium-grade rocks it is clearly introduced, as shown by its relation to the other minerals present. I believe that the ubiquitous tourmaline in regionally metamorphosed rocks is an indicator of the action of 'emanations' throughout all grades.

Whilst I have belittled the role of the dynamic factor in regional metamorphism, it is of course true that in the lower grades it must be of considerable importance. How can this be reconciled with the view that migmatization is the prime cause of regional metamorphism? The reconciliation may be sought, I suggest, in the stresses set up by the increase of volume consequent upon the invasion of the crust by the migmatite front. Relief is obtained in the outer and cooler zones by shearing; in the inner and hotter zones by internal reconstructions. The unity of the zonal series may thus be preserved.

I have shown my predilection for dividing all rock transformations into two groups, one those of dislocation-metamorphism associated with dislocations of the crust, and the other those of regional and thermal metamorphism associated with igneous activity. My remarks, I trust, will receive thorough criticism. I am prepared for this, for, just as things too absurd to be said can yet be sung with perfect propriety, so views too tenuous, unsubstantiated and generalized for ordinary scientific papers can yet appear with some measure of dignity in presidential addresses.

POWDERED FUEL: PROGRESS AND PROSPECTS

THE necessity imposed by the demands of war to make use of any available materials in order to eke out inadequate supplies of the usual commodities is frequently the means of bringing to practical use ideas and inventions which might otherwise languish for years. An example is the introduction in the Napoleonic era of the present method of making soap in consequence of France being cut off from the usual supplies of kelp. The use of powdered fuel in aero-engines may, owing to Germany having difficulty in getting adequate supplies of petrol, be one of the results of the present hostilities; that the Germans have been working in this direction is evidenced by patents covering the use of powdered fuel. Patent literature shows that two distinct methods of operation have been envisaged. One consists in mixing the fuel with air and introducing the mixture into the combustion chamber, thus following the cycle used in petrol engines. The other adopts Diesel practice in injecting the fuel directly into the combustion chamber, though obviously with a fuel in the form of a powder some important modifications at the injection stage would be necessary.

Powdered coal cannot be described as a tractable material for the purpose of being metered out small quantities for injection into the com[illegible]stion chambers of a high-speed engine. Freshly pulverized, it is light and fluffy but, in the presence of moisture it readily tends to change its physical characteristics and to pack itself into a dense and rather inert mass. It is necessary, therefore, that it should be well dried before the final pulverization, and it is desirable also that it should not be kept in storage but rather used at once. After a long period of trial, it has now become well established as a boiler fuel, and a brief statement of its history in this connexion may indicate its possibilities.

In 1831, a patent was granted to John Dawes, ironmaster, for a method of introducing fuel into the blast of furnaces. Later patentees include the name of Mushet who, it will be noted, was also interested in steel furnaces. The first to advocate pulverized fuel seems to have been John Bourne, in whose "Treatise on the Steam Engine" of 1861 it is stated that "the fuel and air must be fed in simultaneously and the most feasible way of accomplishing this object seems to be in reducing the coal to dust and blowing it into a chamber lined with firebrick so that the coal dust may be ignited by coming into contact with the red hot surfaces". In 1868, T. R. Crampton experimented on the use of pulverized coal in steam boilers and puddling furnaces, and the views he put forward in a paper read before the Iron and Steel Institute

1873 have proved to be fundamentally correct. e was strongly insistent on the importance of the ze of the fuel particles and of the intimate mixture air and fuel.

It was not until 1895, when powdered fuel began be successfully used in rotary cement kilns, that e system can be said to have become established. this branch, however, its success has been so arked that it can be claimed to account for about our fifths of the world's output of portland ement. In this same year a remarkable result was btained from tests carried out by Bryan Donkin Berlin. A Cornish boiler was operated for one ay by hand-firing on the ordinary grate; two ays later, after being fitted with the Wegener pparatus, it was given a day's run on powdered oal. On the first occasion the thermal efficiency as 54 per cent, whereas on the second it was 7 per cent, the total duration of smoke in the wo tests being 105 minutes and 6 minutes spectively.

In view of these figures, it is remarkable that e development of this method of firing has been retarded and that in England, even now, the umber of plants in operation is very limited. This not explained by any inherent difficulty, as the ushing, drying, pulverizing and delivery plant re of robust construction and generally reliable operation. The risks associated with the use f pulverized coal can be controlled by strict ttention to cleanliness in the boiler house and to e cleaning of all-pipes when closing down. The owdered fuel is entrained in a limited blast of ir which, before entering the furnace, is enabled carry with it the additional amount of air quisite for combustion. As the carbon dioxide ercentage may be as high as 15, it can be seen hat the proportion of excess air is lower than that eeded for ordinary coal firing, where 12·5 per cent the normal figure for carbon dioxide. The ash roduced is a very finely divided flocculent powder, nd the amount which escapes to the atmosphere an be reduced to any desired degree by suitable terceptors.

The history of the efforts made to use coal dust directly in internal combustion engines is in strong contrast to the record just given, as the main problems have not been satisfactorily solved. It is an interesting fact that when Diesel, about 1890, was planning the type of engine which now bears his name, his primary idea had been to employ coal dust as fuel. After several years of experimental work, the engine which he constructed proved to be adapted to oil fuel but not at all to coal or even gas, and so for this as well as economic reasons its ultimate development was directed toward the utilization of oil. At the Glasgow Exhibition of 1901 there was shown an engine made to the patents of 1894 and 1900 of P. F. MacCallum, which developed 100 B.H.P. at 150 r.p.m., using coal dust as fuel. The difficulty of completely consuming the solid particles was never fully overcome, no matter how finely the coal was pulverized, and this continues to be one of the chief problems to be solved. The ash is also troublesome and inevitably so, for the limited combustion space offers little scope for devising means of interception and control.

These considerations suggest that, instead of the direct use of coal dust in the engine cylinders, some indirect or semi-direct method might be developed. The use of a special form of gas producer is an indirect method, but so much so as to come under a different classification, the engine becoming a gas engine supplied by gas from an individual gas generator. The term semi-direct is intended to suggest an arrangement whereby the processes of combustion are isolated from the cylinder, but in which the working substance is the gas formed by combustion. The indirect method, on the other hand, would be one in which the products of combustion do not enter the cylinder but are enabled through another medium to do work on the piston. It is never possible to forecast how practical conditions may modify theoretical suggestions, and it will be interesting to see by what means the coal-firing of engines, if indeed it is practicable, will be realized.

OBITUARIES

Dr. W. B. Wright

DR. W. B. WRIGHT, lately of the Geological Survey of Great Britain, died on October 11 at the age of sixty-three years. Wright received his university training at Trinity College, Dublin, which 1928 honoured him with the Sc.D. He approached eology through mathematics, being attracted by roll's astronomical theory of ice ages. He joined the Geological Survey of Great Britain and Ireland in 1901, and to begin with had the good fortune to work in the Dublin, Belfast, Cork and Limerick districts under the inspiring leadership of the great glacialist Lamplugh. During these early years Wright's most original contribution was a joint account with Maufe, published in 1904, of a low pre-Glacial raised beach preserved at many points around Ireland. A similar feature had long been familiar to geologists on both sides of the English Channel and in South Wales and Yorkshire.

During 1904, a year before the separation of the Geological Survey of Ireland, Wright came to England. Here in the Midlands he encountered the Millstone Grit and Coal Measures, which later came to mean so much to him. He also learnt at close quarters the elusiveness of the Older Glaciation of this district.

In 1906, eager to rejoin his friend Maufe, Wright transferred to Scotland, where he worked officially in the West Highlands and Midland Valley, and unofficially everywhere on the coastline. His main discoveries were: two earth movements separated by a period of igneous activity and recorded in the disturbed Torridonian of Colonsay; a pre-Glacial 100-ft. beach in the same and neighbouring islands; and north-west symmetry in the Tertiary volcanic centre of Mull. Wright was in at the beginning of the detailed study of Mull, and though one contribution is here singled out for special recognition, he had a lion's share in the elucidation of the whole. Wright also played an important part in developing the coalfield technique of the Edinburgh office of the Survey.

In 1910 Wright was appointed to the Irish Survey, where he did good work during the next ten years. It was in this period that he sponsored a deep bore at Lough Neagh, in search of a concealed coalfield, but the results, published in 1924, proved disappointing from the economic point of view. In 1914 Wright produced his *magnum opus*, "The Quaternary Ice Age", which put all the world in his debt by collecting and correlating in one volume a vast amount of international literature, not easy of access and definitely difficult to assess.

In 1921 Wright was invited to return to England to undertake for the Geological Survey of Great Britain the organization of a branch office in Manchester and the revision of the Lancashire coalfield. His success was outstanding, and his staff has covered the area with excellent maps and descriptive memoirs. He gave special attention to palæontology and to actual inspection of underground workings. At first he studied the Millstone Grit, and here received much help from Bisat, the chief of goniatite experts; but the return he made was generous. Moreover, he brought the modern work to the notice of a wide public in his section on the Millstone Grit contributed to the "Handbook of the Geology of Great Britain", a compilative work that appeared in 1929.

Presently Wright specialized on the Coal Measures, and produced splendid results in the form of subzones, based on freshwater mussels. Like certain others of his countrymen, Wright had a pugnacious tendency, which has perhaps concealed the comradeship that exists in this difficult field, or, one would like to say, pool, of research. He stood for the definition of a fossil species in terms of a type specimen that one can handle, rather than in terms of a synthesis derived from an assemblage of specimens, which, in the researcher's opinion, would have been able to interbreed if they had lived together in tim and space. There is evidently more than one wa of attacking this difficult problem, but Wright method of convenience has certainly given valuabl results, valuable to industry as well as to science.

Wright's latest publications have been a secon edition of his "Quaternary Ice Age" (1937), an "Tools and the Man" (1939). These clearly reve that whatever else caught his fancy on the way, remained ever true to his early glacial love.

Wright is survived by a widow and a daughte both of whom take an active interest in zoology.

E. B. BAILEY

Dr. G. A. Sutherland, C.B.E.

WE regret to announce the death on October at the age of seventy-eight years of Dr. Geor Alexander Sutherland, consulting physician to th North West London Hospital and the Paddingto Green Hospital for Children. Although ill-health h compelled him to retire from practice many yea previously, he was at one time one of the best-know London specialists in children's diseases. He w born in 1861 at Aberdeen, the third son of the Re James Sutherland, and was educated at Aberdee where he graduated M.A. in 1882 and Edinburg where he became M.B. in 1886 and M.D. in 189 after which he took a post-graduate course in Vienn

Sutherland took an active part in the formation 1900 of the Society for the Study of Disease in Chil ren, as well as in the amalgamation of this Socie eight years later in the Royal Society of Medicine. 1906 he was made president of the Pædiatric Secti for the annual meeting of the British Medical Associ tion at Toronto, and in 1911–12 was president the Section for the Study of Disease in Children the Royal Society of Medicine. In addition contributions to periodical medical literature a to Latham and English's "System of Treatment he published in the series of Oxford Medical Pu lications works on "The Treatment of Disease Children" (1907 and 1913) and "The Heart in Ear Life" (1914). In 1917 he delivered the Lumlei Lectures before the Royal College of Physicians, which he had been elected a fellow in 1903, h subject being "Modern Aspects of Heart Disease He was also editor of a "System of Diet a Dietetics" (1908), to which he contributed thr chapters on diet in diseases of the lungs, the feedi of infants and children in health, and diet in diseas of children. During the War of 1914–18 he w appointed consulting physician to the Royal Air For and was created C.B.E. in recognition of his servic He was unmarried.

J. D. ROLLESTON.

WE regret to announce the following deaths:

Mr. T. D. Rice, senior soil scientist of the Bure of Chemistry and Soils, U.S. Department of Ag culture, on September 12, aged sixty-one years.

Prof. R. V. Wheeler, professor of fuel technolo in the University of Sheffield, on October 28, ag fifty-six years.

NEWS AND VIEWS

Nobel Prizes for Physiology and Medicine

Prof. C. Heymans

PROF. CORNEILLE HEYMANS is professor of pharmacology in the University of Ghent, being the direct successor in that chair to his father, the late Prof. . Z. Heymans, in collaboration with whom he had carried out researches, involving some of the inenious methods of cross-circulation and artificial perfusion, which he has later developed in the series f masterly investigations which have just been ecognized by the award of the Nobel Prize for Physiology and Medicine for 1938. Some of Prof. Heymans' most important work has dealt with the sensory mechanisms in the vascular system, through which the arterial blood pressure is kept under reflex nervous control. This sensory function of the carotid sinus had been discovered and described by H. E. Hering and E. Koch in Germany, but the work of Heymans greatly extended knowledge of its imortance and demonstrated the presence of analogous sensory apparatus in other parts of the vascular system. Heymans also discovered the sensitiveness f the carotid sinus to chemical changes in the blood, nd its consequent importance in regulating the activity of the respiratory centre. Prof. Heymans is esponsible for many other important advances in hysiology and pharmacology, largely concerned with the control of the circulation. He is well known utside his own country, and a frequent and welcome visitor to Great Britain, where his remarkable command of English, as of several other languages, nables him to give clear and fluent accounts of the progress of his researches, and where the honour now done to him will be warmly greeted by his many riends and admirers.

Prof. G. Domagk

PROF. GERHARD DOMAGK, who has been awarded he Nobel Prize for Physiology and Medicine for 1939, is the pathologist to the medical and biological esearch laboratories of the Bayer Company of Elberfeld. Domagk was comparatively little known, beyond the range of those familiar with the work of hat institution, until, nearly five years ago, he made a discovery which has led to one of the most rapid and remarkable advances on record in therapeutic science and practice. The late Paul Ehrlich began his researches in chemotherapy with the attempt to find substances which would deal directly, as disinfectants, with bacterial infections in the living body. He, like many others who have followed, abandoned what seemed to be a hopeless quest, and urned his attention to the discovery of chemotherapeutic remedies for infections due to protozoa and spirochaetes, the most important outcome being the discovery of salvarsan. It had almost come to be assumed that bacterial infections were beyond the each of chemotherapy, though Morgenroth's 'Optochin' and its allies had given some hope of eventual success. Domagk appears to have examined a series of dyes for their action on streptococcal infections in the living body, irrespective of a lack of disinfectant properties outside it. In January 1935 he described the remedial effect on streptococcal infections in mice of a red dye, named 'Prontosil', an amide of chrysoidine, which had been prepared by Mietzsch and Klarer, chemists on the staff of the Bayer Company. Some confirmatory clinical results were obtained, but the first organized trial of 'Prontosil' on a uniform series of cases of streptococcal infection in man was made by Colebrook in Great Britain.

MEANWHILE, it had been found by Trefouel, Nitti and Bovet, in France, that a simpler, uncoloured component of 'Prontosil', sulphanilamide, had a similar action; and there seems reason to believe that this is the direct antistreptococcal agent, being split off in the body from 'Prontosil'. Since then, each month has seemed to bring evidence of the therapeutic importance in some new direction of 'Prontosil', sulphanilamide, or one of the numerous derivatives made from the latter in many countries; a conspicuous example being the pyridyl-sulphanilamide (M. & B. 693) made by Ewins in Great Britain, and shown by Whitby to have special activity in pneumococcal infections, such as lobar pneumonia. The result of this development has the aspect of a revolutionary advance in therapeutics, and there will be general satisfaction, among medical research workers and physicians in all countries, that the Nobel Committee have thus recognized the pathologist whose initial discovery opened the way to such a great development.

Prof. V. L. Komarov

IN honour of his seventieth birthday and in appreciation of his great services to science, the Soviet Government has awarded the Order of Lenin (the highest Order in the Soviet State) to Prof. V. L. Komarov, president of the Academy of Sciences of the U.S.S.R. The name of Vladimir Leontievitch Komarov will always be inseparably associated with the flora of Manchuria. Komarov was attached to the Russian expedition to Manchuria in 1896, and during this and subsequent years made extensive botanical collections, duplicates of which were distributed to the principal herbaria of the world. The outcome of these collections was the valuable and detailed three-volume "Flora Manshuriæ", published in parts in the *Acta Horti Petropolitani* from 1901 until 1907. In 1908 Komarov joined the expedition of Theodor Pavlovitch Riabushinsky to Kamchatka, where he remained for two years, collecting assiduously. Accounts of the botanical results of the expedition were published by Komarov in "Zwei Jahre auf Kamtschatka" (1911) and in "Voyage en Kamtchatka en 1908–1909", forming part of the official account of the expedition (1913). During 1931–32, in collaboration with Mme. Klobukova-Alisova, Komarov published a "Key to the Plants of the Far Eastern Region of the U.S.S.R." in two volumes, and in 1934 appeared the first volume of the magnificently conceived and executed "Flora U R S S". This truly monumental work, of which at least seven volumes have already appeared in rapid succession, is the result of the collaboration of numerous Russian botanists under Komarov's general editorship. We sincerely trust that Prof. Komarov may live to see the completion of his crowning work.

German Culture in Prague

A REPORT from the Protectorate of Bohemia and Moravia announces that the German University of Prague has been reconstituted as a Reichsdeutsch University "to serve as a centre for German cultural expansion to the south-east of Europe". This status was made legal on October 1 and necessitates the appointment of Nazi professors to Prague. They are to be accompanied by a large body of students drawn from all parts of Germany. In the past, this German university in Czechoslovakia attracted many well-known specialists from Germany and Austria. Indeed, it was the policy of the former Czech Ministry of Education to encourage such appointments in order to ensure a high standard both of teaching and scientific research. The new appointments are, however, avowedly not for scientific advancement but for Germanization, a process that is being pursued also by the schools throughout the protectorate as well as in the Sudeten territory acquired by Germany in September 1938. Meanwhile, Czech and non-Nazi professors are drafted into labour corps. A number have succumbed to this inhuman treatment, including Profs. Charvat and Bělohradek. Despite the deplorable setback to science and learning in Central Europe, the Czechs are still attempting to continue with their investigations. An instance is afforded by the recent archæological excavations near Mělnik, where a prehistoric settlement has been unearthed. The objects discovered are believed to date from the time when Slav tribes first settled in the Elbe valley.

The Linnean Society

IN addressing the Linnean Society of London meeting on October 26, the president, Dr. J. Ramsbottom, said that the Council had already taken steps before May last to protect the Society's treasures; the Linnean collections (specimens and books) were moved, and the medals and other valuables from the Iron Chest. Since the outbreak of hostilities the Smithian Herbarium and some smaller collections have been moved and stored in what is hoped to be a safe place. It is the unanimous decision of the Council that the Society should carry out its normal activities so far as is possible. This is in the best interest of fellows, of the Society, and of the subjects in which the Society is interested. Apart from the communications at meetings it is essential that biologists should have an opportunity for informa meeting at some central place in London. Therefor the Society is keeping its rooms open and allowin them to be used by other societies or bodies of biologists who are in need of such a meeting-place eithe for formal or informal discussions. In 1914 the time o meeting was altered from 7 o'clock to 5 o'clock becaus of moonlight nights—moonlight nights had bee favoured in the early days of the Society, befor streets were properly lighted. Now because of th black-out it is necessary to hold meetings earlier The next meeting will be held at 2.30 and the following—summer-time being ended—at 2.15.

Museums and the War

ON the outbreak of war many museums wer closed to the public, following the example of th various national museums under Government control It was a regrettable move on the part of the Government, for these institutions are centres of educatio and mild recreation, as well as repositories of valuab specimens, and the use of them would have been a welcome relief from more stern affairs to many of th public and the troops. Now in a pamphlet issued b the Board of Education, entitled "The Schools i War-time" (Memorandum No. 4), "The Use o Museums" is discussed, and we have the curiou spectacle of the president of the Board of Educatio urging the value in war-time of museums and urgi the use of museums, while those museums over whic he has some measure of control remain closed Nevertheless the policy which he urges in thi pamphlet is the right one, and War Circular No. of the Museums Association on "Museums and th War" gives a lead. Not only is it desirable, accordin to this circular, that existing museum services shoul continue, but also that additional educationa services should be provided. Ways are shown i which museums can help. It is probable that i many cases reduction of staffs may render specia efforts impossible; but it is not a serious matter t make halls and galleries, as many as the number o attendants will allow, available for the public.

The Electrical Grid in Great Britain

IN view of the decision of the Institution o Electrical Engineers to hold no meetings of th Institution in London during the first half of th session, a copy of the address of Mr. Johnston Wright, president of the Institution and chairma of the Central Electricity Board, which he would hav delivered normally on October 26, has been posted t every member in the United Kingdom and Eire. Hi choice of the construction and operation of the Gri as the subject of his address was a happy one, owin to the significant coincidence that the incomin president on the outbreak of the War of 1914–1 was the late Sir John Snell, to whose vision, enthusiasm and advocacy the Grid is so largely due. Th deficiencies in national electrical organization reveale by that war resulted in the establishment of the Grid It is not too much to claim that the Grid has a vit national role in the present struggle. The Grid con uction and standardization of frequency planned comparative prosperity of 1924–29 and carried t largely in the period of acute depression which lowed, resulted in a large increase above the rmal capital expenditure of the industry at a time en such expenditure was most needed. The policy d the valuable effect of affording manufacturers in eat Britain extensive and intensive experience in igning and constructing large high-voltage power nt, thus putting them in a position of equality th their competitors abroad.

In 1924–25 seventeen different frequencies were ployed in the A.C. system of Great Britain. The perts advising the Weir Committee considered that standardization desirable for grid purposes, if dertaken in 1924, would cost 10½ million pounds rling. By the time the work was actually put in nd, on dates spread over the period 1928–30, the imated gross cost was 18½ million pounds. The ual expenditure when the work was complete was 3 millions, some part of which is recoverable. Had decision to standardize been delayed until the sent time, the cost would have been well over millions. The savings attributable to the Grid tem, already large, would not have been on the ne scale had standardization not been undertaken. e national defence requirements have undoubtedly n simplified by the existence of a national standard quency basis. In conclusion, Mr. Johnstone Wright d that the parts to be played by the Institution mproving and developing the personnel and equipnt required by the electrical industry and in thering the cause of international engineering operation, are both onerous and honourable.

incarnation of a Dalai Lama

During the five years which have elapsed since death of the Dalai Lama of Tibet, reports have peared of the progress made in the search for his cessor. According to Lamaistic belief, when a lai Lama dies, his spirit is reincarnated in the dy of his successor, born at the moment of his th. The records of early travellers in Tibet bear ness to the elaborate precautions taken to ensure true succession to the holy office, and the careful, everent, regimen to which its youthful occupant subjected. Lhamo Dhondhup, the new Dalai ma, now some five years of age, was born in odo Ari, near Kumbum, in Silling and at his th there was a rainbow over the house. Some rticulars of the signs by which the authenticity of reincarnation was attested, as reported from bet, are transmitted by the Delhi correspondent of e *Times* in the issue of October 29. Not only d the existence of the reincarnated Dalai Lama d his whereabouts been indicated in a vision, ording to precedent, but also when visited by e search party, disguised as traders, he recognized ir holy calling and distinguished between the tus of the individuals who composed the party. took hold of the rosary which had belonged to e late Dalai Lama, telling the beads and repeating the Buddhist formula "Om Mane Padme Hum". In a further test, when the Dalai Lama's rosary, small drum and walking stick were offered him, he chose those which had been his own in his previous incarnation in preference to the replicas presented to him at the same time—a test in which another aspirant to the office failed.

African Studies

In "African Survey", Lord Hailey, in discussing the future of African studies, stressed the fact that there was no less need for organized research in the social sciences than in the natural sciences. It was inevitable in a survey of so wide a scope that any recommendations made would cut across existing activities. This was recognized in the credit accorded to existing organizations, in which prominence was given to the work of the International Institute of African Languages and Cultures, not only on account of its specific interests, but also on account of its facilities for collecting information through its international relations. In the recently issued report of the Executive Council of the Institute (*Africa*, **12**, 4, 1939) it is recalled that discussion of plans for future research had been postponed pending the publication of Lord Hailey's "African Survey". It is now announced that on the appearance of that report, the authorities of the Institute initiated conversations with Lord Hailey with the view of obviating the dangers of overlap in a common field and competition in the sources from which funds are derived. The possibilities of co-operation are now under discussion, and a scheme for associating the continuation of the Hailey Survey work with the work of the Institute has already been approved in principle by the Council for elaboration by the Institute's officers.

British Museum (Natural History): Recent Acquisitions

Mr. Robert W. Oates has presented a portrait of J. J. Audubon, the father of American ornithology. This portrait is a copy by Lance Calkin of the so-called hasty portrait which Audubon drew of himself in Liverpool in 1826, and which was reproduced in Buchanan's life of Audubon. Unable to find sufficient subscribers in the United States for his projected work on the birds of America, Audubon, at the age of forty-one, came to England for the purpose of finding additional supporters. After visiting a large number of towns in England and Scotland, exhibiting his pictures and meeting a number of well-known people, Audubon collected sufficient subscribers to enable him to commence publication of "The Birds of America". This great work—unique of its kind—was published in London in four volumes (elephant folio), with life-size drawings of the different birds, between 1827 and 1838. Mr. J. F. Marshall has presented to the Trustees five large oil paintings of birds by R. Havell, who engraved many, if not all, the illustrations for Audubon's book.

A beautiful specimen of foliated gold in quartz, probably of Australian origin and formerly the property of the late Walter Claude Johnson, founder of Messrs. Johnson and Phillips, has been presented to the Department of Mineralogy through his friend Mr. G. Leslie Wates. Further gifts of tourmaline, sapphire and hæmate from Burma have been made by Mr. A. C. D. Pain. A new find of tektites, small glass bodies of curious shape and unknown origin, has recently been made in Texas and a few good specimens have been acquired by exchange with the University of Texas. Also a slice of the New South Wales meteoritic stone Narellan, new to the Museum collection, has been acquired by exchange with the Australian Museum. Among the few purchases approved by the Trustees are included two good crystals of olivine from the Red Sea, and some parti-coloured tourmalines and cordierite from Brazil. The Department of Botany has received about 1,750 plants from North Burma and Assam collected by Captain F. Kingdon Ward on his latest expedition. He visited China intending to proceed to the Shan States and south-west Yunnan, but after six weeks (a month of which was spent under open arrest) he left China and went to North Burma. In 1938 he spent six months in the Eastern Himalayas and then joined the Vernay–Cutting expedition to the Burma-China frontier.

Electric Propulsion at Sea

A. C. HARDY, in the *Electrician* of October 13, discusses the part that electrically propelled ships are likely to play in the present conflict, and whether this is likely to have a great effect on the future of electrically propelled and Diesel-electric ships. A number of coasters use Diesel generating power not only for propulsion but also largely for winches, windlass and other ancillary purposes. In Amsterdam, turbo-electric vessels are being built and they are now fitting out a pair of 'units' with a special method of propulsion. One of these two ships is the passenger and cargo turbo-electric vessel *Josef Stalin*, designed by the Netherlands Shipbuilding Co. for the Soviet Government, in accordance with the requirements of the U.S.S.R. Shipping Register. This vessel and her sister ship have accommodation for 48 first-class, 164 second, and 296 third-class passengers and also a crew of 102. They have a length of about 133 metres overall with a beam of 18·5 metres, a depth of 9·65 metres and a gross tonnage of about 7,500. It is stated that their turbo-generators deliver about 14,000 S.H.P., to the two shafts. In this respect, on two screws the new ship will develop within 1,000 h.p. of the maximum output of the big German liner *Patria*, the largest Diesel-electric ship afloat. The *Josef Stalin* and her sister ship are expected to have a speed of about 20 knots and they will be among the fastest electric ships in existence. Three large turbo-electric all-welded vessels which were launched recently in the United States have made a great step in advance by using very high pressure and very high temperature steam. If the future should show that there will be a demand for Diesel engines applied to ships having even higher powers than they have at present, it looks as if the struggle for supremacy would lie between Diesel-electric A.C. drive and Diesel-geared drive.

Recent Earthquakes

DR. G. VAN DIJK of the De Bilt (Holland) seism logical observatory recorded fifteen large eart quakes during August and fourteen during Septemb 1939. One of the largest recorded at De Bilt w that of August 3, which probably had an epicent 2,350 km. from De Bilt in an approximately easte direction. Preliminary determinations of epicentr have been made by the United States Coast a Geodetic Survey in co-operation with Science Servi and the Jesuit Seismological Association showi the earthquake of August 12 to have been in t north Pacific Ocean off Japan, that of August 24 the Pacific Ocean near Central America, and that August 26 in the Pacific Ocean near the New Hebride The somewhat deep focus (60 km.) earthquake September 8 had an epicentre in lat. 51° N., lon 175° E., just south of the Andrean Islands, which a part of the Aleutian Islands. This was near t epicentre of the very strong 'missing earthquake' November 10, 1938. The shock of September had its epicentre near the island of San Luis in t Gulf of California in a region which is liable to sm earthquake shocks. Kew reported that six stro earthquakes were registered on the seismograp during September, the latest to be record being on October 10, with a possible epicentr distance of 88° and rather deep focus (75 km.).

Forestry Abstracts

THE Imperial Forestry Bureau at Oxford h commenced the issue of a publication entitl *Forestry Abstracts*. The lines upon which this quarter journal, as it is designated, are based, follow those the well-known *Experiment Station Record* of t United States Department of Agriculture, which now in its eightieth volume. This latter publicati is not, however, confined to forestry. *Forest Abstracts* is intended to record in the Engli language brief reviews and précis of the curre forestry literature of the world. The general idea that each issue will include short reviews of literatu in different branches of forestry, with notes annual forestry reports, and abstracts classified subjects. "In the abstracts the aim is to epitomi the contents of each paper so as to enable the read to judge of its value as a contribution to knowledg The subject headings are as follow : General Forestr Fundamental Natural Laws of the Forest ; Tr Species ; Forest Botany ; Forest Zoology ; Syl culture ; Utilization ; Technology ; Protectio Increment, Yield ; Management, Working Pla Surveys ; Economics ; Administration ; Policy.

Indian Journal of Entomology

WE have received a copy of the first issue of new zoological periodical entitled the *Indian Jour of Entomology* (vol. 1, pts. 1 and 2. June 1939). Th journal is to be published twice a year by the En mological Society of India and the subscription pr abroad for non-members of that Society is Rs. per annum. All communications should be addres to the General Secretary, Entomological Society dia, Agricultural Research Institute, New Delhi, dia. It is intended to publish papers on both pure d applied entomology, besides short notices about w. books and reviews of recent research, etc. The ief editor is Dr. Hem Singh Pruthi who, with five her Indian entomologists, forms the editorial ard. The present number is well produced; it ntains eight scientific articles and runs to 137 pp. gether with illustrations. We wish this new journal ery success, and if it results in the 'localization' of uch future Indian entomological work within its ges, instead of the present diversity of sources for publication, it will prove a definite boon to orkers all over the world.

bliography of Drosophila

Students of genetics have for a long time past eded a guide to the immense amount of genetical rk done on Drosophila. This need has been pplied by the publication of a "Bibliography the Genetics of Drosophila" by the Imperial ureau of Animal Breeding and Genetics. Dr. H. J. uller has compiled not only papers of special terest to workers on Drosophila, but also those ore general papers which shed light on problems hich affect both Drosophila and genetical thought. e bibliography is particularly valuable in that it ovides cross references where several authors are volved in one paper, and in the adequate reference Russian literature.

emical Club

The Chemical Club is continuing to function at its use at 2 Whitehall Court, London, there being od air raid shelters in the premises. There is a eling that the Club will be used more and more ring time of war, since enlarged acquaintanceship d cheerful association are definite factors in the esent national effort. The annual general meeting ll be held at the Club on Tuesday, November 14, 2 o'clock. The popularity of lunchtime meetings nce the war started is expected to result in a good tendance. The report of the executive committee r the year 1938–39 speaks of a year of successful cial and other activities. The Committee has nom- ated for the ensuing year Mr. F. Arnold Green as esident, Dr. H. E. Cox as chairman of the executive mmittee, and the continuation in office of the norary treasurer and honorary secretary, Dr. S. I. vy and Mr. F. J. Bullen respectively. The Com- ittee will recommend to the annual general meeting at in view of the number of clubs which are offering mporary membership to uniformed members of .M. Forces, the Chemical Club should provide rallel concessions by offering facilities, at a nominal bscription, to those who, although not in uniform, e engaged in London on Government work. This mporary measure is one likely to be highly prized chemists and others so situated.

orld Power Conference

Ir. G. J. T. Bakker, chairman of the Netherlands ational Committee of the World Power Conference, as agreed to become acting chairman of the International Executive Council of the Conference during the War. Correspondence intended for the International Executive Council should be addressed to the Secretariat, International Executive Council, World Power Conference, Vereeniging voor Congressen op Electrotechnisch en Aanverwant Gebied, Utrechtscheweg 210, Arnhem, Holland. Correspondence for the British National Committee should, as at present, be addressed to 36 Kingsway, London, W.C.2. Orders for any World Power Conference *Transactions* should be sent to Messrs. Percy Lund, Humphries and Co., Ltd., Country Press, Bradford. Orders for the publications of the Central Office of the World Power Conference, including the Statistical Year-book of the World Power Conference, should be directed to the British National Committee. Special arrangements have, however, been made with respect to "Technical Data on Fuel", orders for which will be dealt with by the Secretary, Society of British Gas Industries, Uplands, Epsom Road, Guildford, Surrey.

Announcements

Prof. E. Schrödinger is now in Dublin, and is delivering a course of lectures which began on November 3 at University College, Dublin, under the title "An Elementary Introduction to Wave Mechanics".

Dr. Icie Macy-Hoobler, director of the research laboratory of the Children's Fund of Michigan, Detroit, has been awarded the 1939 gold medal and the thousand dollars prize of the Borden Company for outstanding research achievement in applied nutrition.

In view of the importance of chemical engineering at the present juncture, the Ramsay Laboratory of Chemical Engineering at University College, London, has reopened, and students will be accepted for training in chemical engineering and research forthwith.

Meetings of the Quekett Microscopical Club are taking place on the third Saturday afternoon of each month at 2.30 p.m. in the Club's rooms at 11 Chandos Street, Cavendish Square, London, W.1.

The general discussion on "The Properties and Testing of Heat Insulating Materials" organized by the Joint Committee on Materials and their Testing in conjunction with the Institution of Gas Engineers arranged for November 23, has been postponed.

Of the two million babies born annually in the United States seventy-five thousand are stillborn, and thirty-nine thousand die during the first month of life. Approximately twelve thousand mothers die from causes directly related to child-bearing, many of which are preventable through combined individual and community action.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 788.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Intensity of Mesotrons in the Upper Atmosphere

IN view of the well-established decay of the mesotron and of the magnitude of the sea-level latitude effect, it is now certain that all mesotrons found have been produced in the atmosphere. It is therefore of great interest to measure their intensities at different heights, particularly at levels where they may be expected to have been produced.

Balloon flights have been made near Edinburgh during the past summer with this object. Triple coincidence counters, shielded with 10 cm. of lead disposed equally between them, have been used. The counters were coupled to a radio transmitter, which was a modified form of that used by Carmichael and Dymond[1]. The thickness of lead was sufficient to absorb completely all electrons. In order to reduce the weight of absorber it was necessary to employ small counters, so that the ground rate of counting was only 0·4 per minute. Because of this small number, the statistical fluctuations in counting during the flights were high, and consequently a large number of flights would be required to obtain an accurate picture of the variation of intensity with height. As the work has now to be broken off, it seems desirable to record the results so far obtained.

Three flights have been made, which indicate that the intensity of vertically directed mesotrons rises to a maximum at a pressure of about 80 mm. mercury (16 km. height), the same point where the maximum for all particles (unshielded counters) occurs, and that its value at this height is approximately nine times the ground value. This should be compared with the increase of about forty times found by Pfotzer[2] and by Carmichael and Dymond[1] with unshielded counters. It is probable that the true increase is even less than this, as the counters, being only shielded in the vertical direction, can record showers coming in laterally. Soft showers of this nature are likely to be numerous at these altitudes, but at present there is no means of finding what correction must be made for them. At heights greater than that corresponding to a pressure of 80 mm. mercury, the intensity appears to decrease rapidly, but the rate of decrease is uncertain, due to the statistical errors mentioned.

These results are of particular interest when viewed in conjunction with Euler and Heisenberg's theory[3] of the intensity variation of mesotrons in the atmosphere. Their assumption that the maximum production of mesotrons occurs at the maximum of the normal transition curve in the atmosphere is shown to be correct.

Also, from the observed ratio of intensities at the ground and at the maximum, some conclusions as to the energy distribution of the particles at their formation can be made. Euler and Heisenberg have assumed that the number of mesotrons with energies greater than E is given by $J(E_0/E)^{\gamma}$, where $\gamma = 1 \cdot 87$. This is the same distribution as that of the primary particles as shown by the latitude effect, and th show that it leads to the correct energy distributi at sea-level. If we exclude all particles of energy le than $1 \cdot 2 \times 10^8$ ev., which will be unable to traver the lead between the counters, their results lead the total intensity at 80 mm. mercury pressure, bei 390 times that at the ground, compared with t observed value of nine.

The discrepancy can be removed, however, if assume that there is a minimum energy with whi mesotrons are produced of about 8×10^8 ev. If t energy distribution is cut off at this value, Eu and Heisenberg's expression leads to the right val of the intensity ratio at the two heights.

The method of formation of the mesotrons is st unknown, although there is some evidence that th are produced by protons and not by shower partic It should be noted, however, that the minim energy of primary electrons in the latitude of Edi burgh is 2×10^9 ev., which is degraded by show formation to from 5 to 7×10^8 ev. at 80 m pressure, the same order of magnitude as the mi mum energy of the mesotrons.

In conclusion, I must thank many of my colleag in the Department for their assistance with t balloon flights, and in particular Dr. C. B. Chil and Mr. A. Cowie.

Absolute Measurement of Electrical Resistance

IN recent years, at Birkbeck College, attention h been given to various methods of measuring electric resistance absolutely. On the eve of war, this seri of researches has been brought to a conclusion. the development of a method in which the potent difference across a resistor is balanced by the avera E.M.F. of a commutating generator. Although Ros so far back as 1909, suggested such a method a proposed a form of apparatus, difficulties we encountered and no experimental data derived fro any form of this method have been published. T method is attractive in requiring only the measureme of a frequency and a maximum mutual inductance.

By a new method, the rotor is made to have su an extremely flat maximum of mutual inductan with the field coils that, over a range of some 1 in the neighbourhood of commutation, no E.M.F. generated. Further, over an adjustable portion this range, covering the actual commutations, t rotor together with additional resistance is sho circuited, thus enabling the E.M.F. across the resist to suffer no interruption but to supply instead t extra quantity of electricity absorbed by the rot virtue of its self-inductance, on establishment of current through it at each commutation. In this y the two main errors associated with break and f-inductance are set against one another, and utralization is readily effected by experimental test der conditions in which these errors are magnified. The apparatus is designed for the accurate and pid measurement of resistances of approximately e ohm. The rotor has a constant speed of 12·5 volutions per second, and the maximum mutual luctance of some 20,000 μH permits of fine justment within ± 1 per cent. An accuracy of a w parts in one hundred thousand has been attained. It is hoped to publish complete details of this vestigation elsewhere.

Interfacial Activity of Short-Chain Isomers

IT is well known that when two long-chain com-unds, stereoisomeric with one another around a uble bond, are adsorbed at a surface, they influence tension there to extents which differ according the effective chain length. Recent experiments me have shown that although the thermal agita-n of short-chain adsorbate molecules at a water – air erface prevents any appreciable fall in the surface sion of the solvent, orientation of many small lecules does occur at a water – oil interface. In ny cases this is sufficiently marked to reveal eresting differences in interfacial activity between rt-chain isomeric compounds, of classes not usually arded as surface active. Further, these differences be reproduced with an accuracy which enables h measurements to be used as a means of tinguishing between the isomers.

Experiments have been carried out on two stereo-meric thio-ether compounds of quadricovalent tinum (kindly supplied by Prof. W. Wardlaw). e results shown in Table 1 were obtained by thods previously described[1], and indicate that ile the *trans*-compound has no surface activity, attraction of the benzene phase for the ethyl ups is sufficient to cause appreciable orientation the *cis*-molecules at the interface.

Further evidence for the surface adsorption of rt-chain molecules is furnished by the dibasic ds. The results in Table 2 show that, although leic and fumaric acids are not sufficiently amphi-thic to be surface active, the additional methyl up in mesaconic and citraconic acids separates the drophobic and hydrophilic centres of the *cis*-mole-e sufficiently for orientation at the interface to ur. Similar well-defined differences can be observed der suitable conditions between *cis* and *trans* forms of benzaldoxime, and are to be expected with the isomeric diazotates.

TABLE 1.

Interface Pure water and :	Interfacial tension (dynes per cm.)
re benzene	35 41
1 per cent solution of *trans* compound : 	35·30
1 per cent solution of *cis* compound : 	28·62

TABLE 2.

Interface Benzene and :	Interfacial tension (dynes per cm.)
Pure water	35·41
1 per cent solution of maleic acid	35·41
1 " " " fumaric "	
1 per cent solution of mesaconic acid (*trans*)	35·41
1 " " " citraconic acid (*cis*)	28·51

Differences in interfacial activity also existing between short-chain *structural* isomers such as the toluic acids, cresols, phthalic acids and butyl alcohols are regarded as additional evidence that interfacial orientation does, in fact, occur in many cases where the adsorbate molecules have been previously considered too small to display any marked amphipathy.

Fibre-Follicle Terminology in the Mammalia

A CONSIDERATION of recent investigations[1-4] into the early development of the coats and fibres of various breeds of sheep and also of other mammalian types suggests the need for a standard follicle nomenclature. It has been found that the types within the follicle population and their group arrangement in the skin of the fœtus and lamb are among the chief factors which determine what type of staple and fleece will be produced. It is obviously necessary, therefore, to agree upon a consistent terminology if research in this field is to be intelligibly co-ordinated. The accompanying table indicates the present confusion and incorporates our suggestion for a terminology which is simple and, on the basis of our present knowledge, adequate enough to cover all the important follicle types in the mammalian coat.

It is now well established that the basis of the follicle bundle is usually the trio group, that is, a group of three follicles which in the sheep has a special significance in that it produces certain special types of fibres. Other and smaller follicles develop later in association with each trio to complete the follicle bundle. First, then, there are these two clearly defined growth stages, namely: (1) the phase leading to the formation of the trio group; (2) the succeeding or post-trio phase.

In order to make the distinction clear, we suggest that those follicles which are differentiated during the first phase should be termed *primary follicles*, and those comprising the second phase, *secondary follicles*.

All the trio follicles are therefore primary, but in some types it is possible to subdivide the central members of the trios into two categories, namely: (1) those which are differentiated early in the first phase; (2) those which are differentiated later in the first phase.

The earlier and therefore more advanced series of central trio follicles we now term *primary X follicles* and those which belong to the later stages of the first phase, *primary Y follicles*. It is important to add, however, that, at least in the Merino breed, not all primary *X*- or *Y*-follicles become the central members of a trio. Occasionally one remains separate

FOLLICLE TERMINOLOGY, NEW AND OLD

Proposed New Terminology	Duerden (1939)	Gibbs (1938)	Galpin (1935)	Wildman (1932)	Toldt (1911) and Hofer (1914)	Spottel and Tanner (192
PRIMARY FOLLICLES	— TRIO FOLLICLES					
(a) Central trio follicles — *primary X* *primary Y*	— (a) central trio follicles	— primary follicles secondary follicles	— X follicles Y follicles	primary follicles secondary follicles	—Mittelhaar follicles	Leithaar follicles
(b) Lateral trio follicles — *primary x* *primary y*	— (b) lateral trio follicles	— tertiary follicles	— x follicles y follicles	lateral trio follicles	Stammhaar follicles	
(c) Couplet follicles — *primary X + x* *primary Y + y*						
(d) Solitary follicles — *primary X or Y*						
SECONDARY FOLLICLES	POST-TRIO FOLLICLES	Quaternary follicles			Beihaar follicles	Gruppenhaa follicles

and distinct throughout the whole period and may be termed a 'solitary' follicle. A few may become associated during the first phase with only one lateral follicle, and these have been termed 'couplets'.

We are of the opinion that this terminology, whilst it recognizes the follicle types described by other workers, eliminates confusion by clearly distinguishing the follicles characteristic of the two main growth phases which are so important in any consideration of the basis of fleece structure.

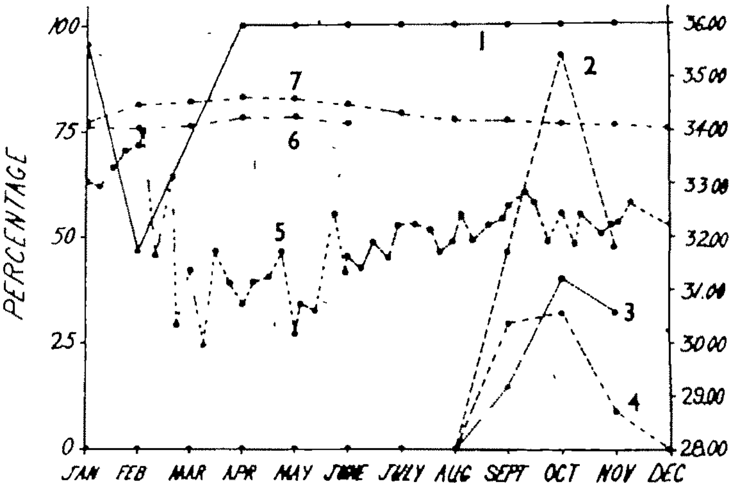
Sagitta as an Indicator of Water Movements in the Irish Sea

IN a recent study[1] on the occurrence of the planktonic genus Sagitta in weekly collections at Port Erin 1928–37 (excepting 1935) and the Mersey Channel, Morecambe Bay, Anglesey coast 1937, interesting facts have emerged. It seems desirable to give some of the results here pending publication of the whole. Two species are found: *S. elegans* Verrill, the oceanic form[2], is predominant at Port Erin; *S. setosa* J. Muller, the coastal form, is predominant in Liverpool Bay and is recorded here for the first time. *S. elegans* is absent from the Liverpool district until February–March, when an influx occurs correlated with the appearance of high salinities (see graph). *S. setosa* is absent from Port Erin until September–December with a maximum in October (see graph). These interchanges of species occur at about the periods of the equinoctial tides and indicate (*a*) extensive mixing of inshore and offshore waters in the greater volume and movements of the equinoctial tides, and (*b*) the occurrence of relatively stable bodies of water in Liverpool Bay in periods between the equinoxes. The occurrence of relatively stable bodies of water oscillating in estuaries l long been known, but stability in an open bay su as Liverpool Bay is of great interest and worthy further investigation.

S. elegans appears to have one main spawni period, January to May, while *S. setosa* appears have at least two, namely, April to June and Augu. The winter brood of *S. setosa* attains a larger aver size than the summer brood.



PERCENTAGE *S. setosa* IN TOW-NETTINGS IN THE LIVERPOOL DISTRICT 1937 AND AT PORT ERIN 1928–37 (EXCEPT 1935) ARE GIVEN WITH SALINITY READINGS ‰ AT THE BAR LIGHTSHIP (1937) AND MEAN MONTHLY SALINITIES AT PORT ERIN FOR 1936 AND 1937.

S. setosa		Salinity	
1. Liverpool District 1937	3. Port Erin 1936	5. Bar Lightship 1937	7 Port Erin 19
2. Port Erin 1937	4. do. 1928–34	6. Port Erin 1937	

Data on the rates of growth, time of sexual matur and relative abundance of the two species at differ seasons of the year, with a discussion on sexual cycles, will, it is hoped, be given by one of (E. L. P.) later.

We are indebted to the Oceanography Depa ment at the University of Liverpool and the staff the Port Erin Biological Station for the data salinity.

Sponge Mortality at British Honduras

A HEAVY mortality among commercial sponges, similar to the Bahamas mortality reported by Galtsoff, Brown, Smith and Smith[1], has appeared among sponges off the coast of British Honduras. The disease appeared first in the Bahamas in December 1938, on the north coast of Cuba in February 1939, and at Key West, Florida, in March. Losses were first reported from British Honduras in June and continued to appear during July and August.

Investigations were carried out in British Honduras by me during August and have yielded the following results.

The sponges, for the most part under cultivation, grow upon grounds within Turneffe lagoon, which is enclosed by islands and communicates with the sea by small creeks and larger channels. The sequence of infection, as recorded by Government and private sponge planters, has followed the general trend of water movements within the lagoon. Originating near a large opening from the sea, the mortality spread first to the more open waters to leeward and only later appeared in more deeply embayed areas, and in areas broken up by small cays.

During the months of April, May and June rainfall was less than 25 per cent of the amount recorded in previous years and water temperatures were generally higher. There is evidence that the salinity during June reached very high values, but unfortunately accurate figures are not available. In July and August the conditions of drought, high temperature and salinity were replaced by normal conditions, and in August accurate determinations placed temperature and salinity within the range of observation for previous years, although the mortality remained unchecked.

Examination of plankton collected with 120 mesh per inch silk townet during August showed no unusual constituents or abnormal quantities of the species normally present. In accordance with previous examinations, a general paucity of life was disclosed.

The microplankton was also poor, except for the presence of bacteria, considered to be the food of the sponges. Bacterial examination showed 2,000–30,000 organisms per c.c. in various parts of the lagoon during August. This compared with 2,000–25,000 observed during May.

No unusual mortality was observed among other forms of life in the lagoon. Non-commercial sponges remained unaffected by the disaster.

Microscopic investigation disclosed the presence of fungus-like filaments in the great majority of dying sponges examined. In appearance, spread of infection through the individual sponge, and greater abundance in the transition zone between dead and living tissues, the organism was indistinguishable from that held probably responsible for the Bahamas disease. Apart from the fungal filaments no organisms have been observed other than those characteristically appearing after the onset of decay.

The successive appearance of the mortality at Key West and at Turneffe and the local progress of the mortality along the path of water currents renders it probable that the disease organism was transmitted from Key West to Turneffe by an ocean current. The strong current running counter to the Gulf Stream along the shores of the Gulf of Mexico and the Gulf of Campeche has a velocity varying from 0·5 to 2 knots. The time elapsed between the appearance of sponge damage at Key West and at Turneffe is ample for transmission of the organism by this current.

At the time of writing no further damage has been reported from Turneffe since the middle of August.

Transplants of Sea-Island Cotton

WITH regard to the statement made by Prof. Macbride in NATURE of February 4, p. 205, that "the effort to transplant sea-island cotton from islets off the coast of Carolina to other parts of the world has resulted in failure. In a few years the transplanted cotton reverts to the native stock", the following facts, which do not quite support this view, may be of interest.

Sea-island cotton has been grown at the Government Agricultural Farm, Sakrand, Sind, for at least ten years, and the samples raised at this Farm have been regularly tested at this Laboratory since 1929–30. It has been found that in the second year of tests (1930–31) the mean fibre-length dropped from 1·44 in. to 1·25 in., but since then it has remained more or less the same with the exception of 1936–37 when it declined temporarily to 1·18 in. The mean fibre-weight per inch has remained remarkably steady at about $0{\cdot}117 \times 10^{-6}$ oz. From the Farm the cotton spread to the cultivators' fields, and in 1935–36 the area under its cultivation stood at 1,400 acres, giving a crop of about seven hundred bales. Since then the area has decreased sharply, not because of any deterioration in its fibre-properties, but because of its poor yield, which prevented the cultivators from getting adequate monetary return for their labour.

It will thus be seen that at least during the last ten years it has not reverted, when grown in Sind, to the native stock, which is a *neglectum* type having a mean fibre-length of about 0·70 in. and a fibre-weight per inch of about $0{\cdot}300 \times 10^{-6}$ oz., that is, nearly half as long and three times as coarse in staple as the Sind sea-island cotton. Its yield, however, has not been satisfactory, and it may be said to have failed on that account.

Myzus ornatus a Vector of Potato Viruses

TOWARDS the end of 1932, aphids later identified as *Myzus ornatus*[1] were found feeding on clover plants in a glasshouse at the Agricultural College, Glasnevin. The species has since been recorded on a wide host range which includes potatoes, a fact which prompted the carrying out of tests to ascertain the efficiency of this species as a vector of potato viruses.

It was used in three separate trials as a vector of leaf roll, and the results showed that out of sixteen healthy potato plants colonized with *Myzus ornatus* from a leaf roll source, ten developed leaf roll. In two trials as a vector of virus Y, five out of sixteen healthy potato plants became infected with this virus. Negative results have so far been obtained in trials with viruses X and A.

Myzus ornatus has been found to only a very slight extent feeding on field crops of potatoes in Eire, consequently it is probable that it is not important as a vector of potato viruses under field conditions. In view of its wide host range and of the above results, and on analogy with *Myzus persicae*, it is probable that *Myzus ornatus* may act as a vector of viruses of crops other than the potato.

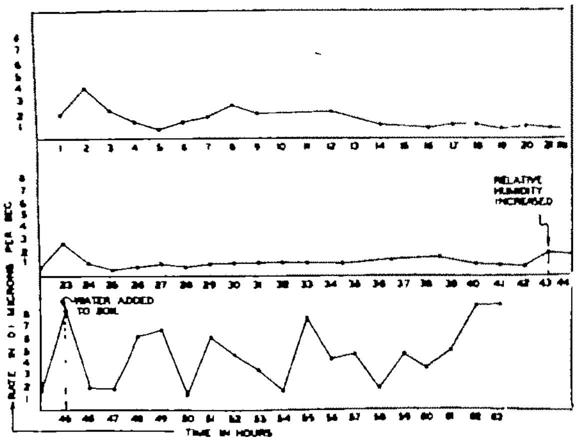
Determination of Growth-Rates by the Optical Lever Method

Rhythm was suspected to occur in the growth-rates of seedlings but it could not be detected with the ordinary microscopic methods. The method described here is promising and proved to be accurate and practical.



Rhythm in cell proliferation is habitually retained in spite of certain variations in the periodicity which are induced by changes in the environmental factors. This kind of rhythm cannot be detected directly, but only by means of histological methods. Growth by cell enlargement increases the bulk considerably in a short time, which makes it probable that a sufficiently sensitive method should make it possible to detect rhythm by direct measurement of growth rates, if it exists at all.

There is good reason for thinking that the elaboration of phytohormones of the bios group and that of the phytohormones of the auxin group are correlated. Since the bios factors regulate the process of cell proliferation and the auxin factors regulate cell enlargement, it is probable that rhythm in cell enlargement must exist and that it is correlated to the rhythm observed in cell proliferation. The optical lever method should yield satisfactory evidence of rhythm if it exists.

The optical lever method offers several advantages over the microscopic methods. It is not necessary to mark the seedling; the seedling need not be disturbed during the period of observation; the seedling need not be exposed to light; the factors influencing the growth-rate may be controlled during the observation; the scale reading varies constantly with the growth and may be recorded at any time; the sensitivity may be increased beyond the limits possible in the microscopic method. In the set-up which we employed in recent experiments the direct reading was 0·002 mm.

A galvanometer mirror was mounted on the balance wheel of a watch movement. It reflected a beam of light, coming from a scale, which turned through an angle that was twice as great as the angle through which the wheel turned. The beam was observed through a telescope, where the scale was read with the aid of a reticule. A light glass arm was mounted on the wheel and had a small bead on the distal end. The movement of the growing point turned the wheel. Friction at the point of contact was slight, and in the jewel bearings of the wheel, negligible. The moment of inertia of the system was small. A force of 5 mgm. applied at the bead was sufficient to raise the lever arm. If the wheel was turned through an angle that was greater than was permitted to obtain accurate results, the scale reading was automatically thrown out of view. The elevation of the arm produced by growth was easily compensated by means of a rack and pinion adjustment mounted on the standard which carried the system. Without this arrangement the optical lever method would not be practical.

The displacement of the bead is determined from the formula:

$$E = \frac{pp'}{2D} \times L,$$

in which E is the displacement; pp' the difference in consecutive scale readings; L the length of the lever arm and D the distance from the scale to the mirror.

D was determined directly and found to be 4456·0 mm. L was determined approximately with callipers at first and then precisely by using the formula, but determining E with a measuring microscope. It was found to be 20·50 mm. By actual trials the probable error for our set-up was found to be less than 0·2 microns.

The seedling was placed on an adjustable stand which made it possible to bring the growing point into contact with the bead without disturbing the set-up, which was adjusted so that readings could be taken immediately after contact was made. This feature is of practical importance in the method.

The seedling was kept in a chamber which had an adjustable side. This side had a small aperture through which the beam of light could go to and from the mirror. The chamber made it possible to control the light, the temperature and the relative humidity.

One example will suffice to illustrate the method. The seedling grew in a substratum of peat and sand. It was watered with standard Knop solution at the time of planting and not again except forty-five hours after recording had begun. Seventy-two hours after planting, when the hypocotyl was just emerging from the soil, contact was made between the hypocotyl and the bead. The temperature was 72° F. throughout the period of the experiment; the relative humidity was 90 per cent before the recording began, 70 per cent for the first forty-three hours of recording and 95 per cent for the remaining hours.

The growth-rate is given graphically in the accompanying figure. It increased somewhat with the relative humidity and the increment could be noted after six minutes. The addition of water to the soil increased the rate very much, which was noted one nd one half minutes after watering, and made the eriodicity much more pronounced.

The plant never ceased growing. The periodicity as evident before and after the changes in the nvironmental conditions. The average value of the rowth-rate was calculated for each hour of the three ycles. From the values obtained, the general verage rate of growth was obtained and found to e 1·092 mm. per hour. Employing this value the alculated final height was 6·8 cm. By actual easurement it was found to be 6·4 cm. The evidence ustifies the conclusion that the method is accurate nd practical.

lavin-Adenine-Dinucleotide in Tissues of Rats on Diet Deficient in Flavin

Ochoa and Peters[1] found cocarboxylase decreased n tissues of pigeons fed on a diet deficient in vitamin B_1. Axelrod and Elvehjem[2] reported a diminution f cozymase in tissues of animals on a nicotinic acid ree diet. We now find a similar diminution in the lavin-adenine-dinucleotide content of boiled extracts f tissues from rats fed on a diet deficient in flavin. he rats (average weight 35 gm.) were fed a ynthetic diet of rice starch, casein (alcohol extracted), alt mixture, supplemented by cod liver oil, crystalline itamin B_1 hydrochloride, a 50 per cent alcohol east concentrate[3], and a liver filtrate from a revious fuller's earth and franconite adsorption. hese supplements were flavin-free.

Mean flavin-adenine-dinucleotide content of rat tissues (expressed in μ gm./gm. fresh tissue).

Group	Diet	No. of animals	Mean weight increase (gm. ± 2 × S.E. mean)	Tissue	Mean nucleotide (± 2 × S.E. mean)
A	Flavin deficient	6	14·9±4·0	Brain	10·5±0·6
				Heart	38·0±5·0
				Kidney	72·4±11·0
				Liver	40·7±10·0
B	Flavin deficient plus 50 μ gm. flavin per day	6	79·8±14·0	Brain	13·0±2·2
				Heart	93·2±17·9
				Kidney	78·6±12·5
				Liver	87·3±22·2

The nucleotide was determined after the method f Warburg and Christian[4], and solutions standardized from a pure specimen kindly sent by Prof. O. Varburg. Group A, fed the above diet for 5 weeks, ncreased in weight but slightly (see table), while roup B, receiving in addition 50 μgm. flavin per day, ad a normal growth rate. Some rats in Group A howed a dermatitis, especially around the eyes, and thers (results not recorded in table) died before the onclusion of the experiment. It is seen that the ean flavin-adenine-dinucleotide values of Group A re all lower than those of Group B. This is especially o in the case of heart and liver tissue. Application of isher's *t* test to the difference of means of the heart nd liver figures gives *t* = 6·1 and 3·81 respectively. or *P* = 0·01, *t* = 3·17. These figures are thus early significant, and afford direct evidence of a urther instance of a deficiency in the vitamin B omplex affecting biological oxidation systems.

These results will be reported in detail elsewhere.

We are indebted to the Nuffield Trustees and the Hildebrand Harmsworth Trustees (Merton College) for financial support.

Note added in proof. In a letter which has just appeared (Nature, 144, 670; 1939) Axelrod, Sober and Elvehjem report a decrease of *d*-amino-acid oxidase in kidney and liver of rats fed on a flavin-deficient diet, suggesting a deficiency of its coenzyme. Our own independent results furnish the direct proof of this.

Mechanism of Decomposition of Hydrogen Peroxide by Catalase

We have recently suggested[1] that the decomposition of hydrogen peroxide by catalase is brought about by the successive reduction of the catalase iron by the peroxide and its re-oxidation by molecular oxygen; the reaction proceeding according to the following equations:

$$\begin{array}{l} 4Fe^{\cdot\cdot\cdot} + 2H_2O_2 = 4H^{\cdot} + 2O_2 \\ 4Fe^{\cdot\cdot} + 4H^{\cdot} + O_2 = 4Fe^{\cdot\cdot\cdot} + 2H_2O \\ \hline 2H_2O_2 = 2H_2O + O_2 \end{array}$$

The evidence supporting this suggestion can be summarized as follows:

(1) It can be shown spectroscopically that the trivalent iron of azide- or hydroxylamine-catalase is rapidly reduced by hydrogen peroxide, although a powerful reducing agent such as sodium hyposulphite reduces neither the free catalase nor its azide or hydroxylamine derivatives.

(2) The reduced azide- or hydroxylamine-catalase is readily re-oxidized by molecular oxygen but not by hydrogen peroxide or potassium ferricyanide[2].

(3) It has been demonstrated manometrically that the complete removal of oxygen inhibits the catalytic activity of the enzyme by at least 88 per cent in acid phosphate solution and only by 40–70 per cent in a more alkaline phosphate buffer solution. The remaining activity of the enzyme in these experiments is due to a slow non-enzymic decomposition of hydrogen peroxide, which increases with the *p*H, and which liberates a sufficient amount of oxygen to promote the catalytic activity of the enzyme[1].

In our oxygen-free manometric experiments, strong or even complete inhibition of catalase was obtained only when the non-enzymic decomposition of hydrogen peroxide was almost completely abolished. The formation of oxygen during the experiments from non-catalytic decomposition must be avoided because, according to the cyclic mechanism of decomposition proposed by us, the slightest trace of oxygen can, by initiating a series of oxidations and reductions, bring about an extensive decomposition of hydrogen peroxide limited only by the stability of the enzyme preparation. The experiments, therefore, had to be carried out in absence of impurities containing other catalytic metals or hæmatin compounds, at a low *p*H, in thoroughly cleaned flasks and using purified reagents. Moreover, the small amount of oxygen evolved from hydrogen peroxide even under these conditions was rapidly eliminated from the solution by shaking it vigorously in a thin layer.

Our results have been challenged, however, by Johnson and Schouvenburg[3], who claim to have been able to demonstrate that the catalytic decomposition of hydrogen peroxide by catalase may take place in the complete absence of molecular oxygen. Their evidence is derived from a qualitative experiment showing that hydrogen peroxide added under strictly anaerobic conditions to luminous bacteria is decomposed by the catalase of these bacteria. The liberation of oxygen is shown by the appearance of luminescence in these bacteria, which was previously extinguished owing to the complete absence of oxygen. These experiments have been carried out with catalase of living and lysed bacteria, naturally in the presence of a great many of other intra- and extra-cellular catalysts and in strong buffer solutions at pH 7·3; in other words, under experimental conditions, which, as we have clearly shown in our paper[1], would reveal only a partial or even no inhibition at all of the activity of catalase.

On the other hand, if we assume that the catalase in their experiments was strongly (90 per cent) inhibited, which is very improbable, the remaining catalytic activity would liberate a sufficient amount of oxygen to induce luminescence in their bacteria. We can say in conclusion that their experiments, far from disproving our results, show only that th qualitative tests with luminescent bacteria are very little use in the study of this problem, for whi reliable and strictly quantitative methods are alrea available.

Tables for Statisticians

In my review of "Statistical Tables", by Fish and Yates (Nature, September 23, p. 533), I referre to the "interesting innovation of providing mea differences for half the interval only". Dr. L. Comrie has pointed out to me that this practice followed in E. V. Huntington's "Four Place Tabl of Logarithms and Trigonometric Functions", and gladly take the opportunity of acknowledging th fact.

J. Wishart.

School of Agriculture,
Cambridge.

Points from Foregoing Letters

The intensity of vertically directed mesotrons at different heights in the atmosphere has been measured by E. G. Dymond in a series of balloon flights. It is found that the intensity rises to a maximum of nine times the ground level value at an air pressure of about 80 mm. mercury. In order to bring the theoretical intensity variations, derived by Euler and Heisenberg, into agreement with these experimental results, it is suggested that there is a minimum energy of formation of mesotrons in the upper atmosphere, of about 8 × 10^9 ev.

H. R. Nettleton records the conclusion of a series of researches on the absolute measurement of electrical resistance by the development of a method which utilizes the average E.M.F. of a commutating generator. He describes how difficulties associated with the method have been overcome, and states that resistances of approximately an ohm can be measured rapidly with an accuracy of a few parts in a hundred thousand.

C. C. Addison finds some interesting differences in interfacial activity between short-chain isomeric compounds of classes not previously regarded as surface active. Interfacial tension measurements may be used to differentiate between such structural or stereoisomeric compounds.

A. B. Wildman and H. B. Carter indicate the present confusion in the terminology of fibre-follicles in the Mammalia. They suggest a new terminology which recognizes clearly two main growth phases and which should make possible a more intelligible co-ordination of research on the development of the mammalian coat.

E. Lowe Pierce and J. H. Orton find that *Sagitt elegans* is predominant or exclusively present at Por Erin and *S. setosa* in Liverpool Bay, except durin equinoctial tides when interchange of species occur It is inferred that extensive mixing of inshore and of shore waters occurs at equinoctial tides and that other periods a relatively stable body of water exis in Liverpool Bay.

Mortality among sponges off the coast of Briti Honduras is reported by F. G. Walton Smit Evidence is given to show that the probable cause identical with that of the recent Bahamas mortality the time and place of appearance support the sugge tion that the disease has been transmitted by ocea currents.

The aphid *Myzus ornatus* is found by J. Loughnane to be a vector of certain potato viruse In view of this ability and of its wide host rang it is suggested that this species may act as a vect of viruses of plants other than the potato.

S. Ochoa and R. J. Rossiter report a decrease the flavin-adenine-dinucleotide of Warburg an Christian in the heart and liver of rats fed on flavin-deficient diet, providing another instance of deficiency of the vitamin B complex affecting biological oxidation system.

D. Keilin and E. F. Hartree find that the decomposition of hydrogen peroxide by catalase is broug about by the successive reduction of the catala iron by the peroxide and its reoxidation by th molecular oxygen. This is in contradiction to th view of Johnson and Schouvenberg, which was base on qualitative tests with luminous bacteria.

RESEARCH ITEMS

rmanation'

HERMANATION', Hanns Weltzel explains (*J. Gypsy e Soc.*, Ser. 3, 18, 4; 1939), is derived by the sies of Germany from the German 'harmonieren', the sense of 'getting on well with'. If this is rect, it is remarkable that the *Sinti* should have opted a German term for so characteristic and cient an institution. It is centuries old among rman gypsies or rather among *Sinti* only. It is basic principle in the structure of their unity. is the union of a small group of gypsies, in which number of families is not limited, and the leader not a chief, but a 'dispenser of justice', or 'judge'. e Hermanation also applies to a definite localized up. Most of the gypsies of central Germany ong to one. The 'Kartepoor' is so called m the beautiful tail feather of the moor-cock, ich hunters often wear in their hat. Members one Hermanation would not eat with those onging to another. Sometimes the term is used a synonym for a meeting, when it is equivalent to *llu*, the gathering at which matters concerning psy law are discussed, and marriages, dispensations justice, cases of outlawry, and the like are settled. m this it follows that Hermanation denotes a uping of families which, on the basis of a bond of ationship, subjects itself to its senior member and colleagues in matters of definite custom. The dge', who was in no sense a 'chief' or 'king', had to a person of reputation and unblemished character the gypsy sense), of imposing appearance, and of re gypsy blood. Supplementary information con- ns ceremonial purity, in which taboos relating to men are stressed: for example, the sole of a woman's e renders things unclean, and hence it is never nded; while among the Krauses a woman carrying ug or bucket must hold it away from her body.

nas of Bengal

ON various occasions in 1933–35, Minendra Nath su carried out investigations of the physical, ial and cultural peculiarities of the Buna colonies Bengal (*J. Department of Letters*, Univ. of Calcutta, , 1939). The Bunas are an aboriginal people of ngal, probably immigrants from Chota Nagpur, racted by the demand for 'landless' labour. ma is a name given them as a 'wild' people, ugh there are other interpretations. In the lages they live in separate areas; and the state- nt that they are hated by Hindu and Mahom- dan alike on account of their fondness for fowl d pork is correct; but nevertheless a large amount intermixture with the two communities has taken ce. Anthropometric measurements and observa- ns of 220 subjects show skin colour (unexposed) rying from tawny white to dark; hair wavy, but th 1·5 per cent woolly; in colour, black, dark own or grey. Eye slit horizontal, or straight; eye- our dark brown, 65 per cent, with medium and ht brown as variants. The nose is generally aight, though convex noses occur; no alveolar gnathism, and facial prognathism slight; lips dium, 85 per cent without eversion; the chin is minent; and the body musculature is marked. e following are the percentages for: (1) stature, le, ranging from 130·0 (very short) to 179·9 (tall); the highest percentage is 82·5 in the group 150·0–159·0, the next highest percentage being 9·5 in the group 160·0–169·9; females, range 140 (short) to 152·9 (below medium), 65 per cent being in the group 140·0–149·9; (2) cephalic index, males, dolichocephalic, 41 per cent, mesocephalic, 54 per cent, brachycephalic, 5 per cent; females, 40 per cent, 20 per cent, and 40 per cent respectively; nasal index, males, leptorrhine 26 per cent, mesorrhine 70·5, platyrrhine 3·5; females, 5 per cent, 80 per cent and 15 per cent respectively. On analysis it appears that the Bunas are a highly mixed group, of which the basic stock was probably indigenous to Chota Nagpur, but which afterwards intermixed freely with the peoples of Bengal, Brahmans, Kayasthas, and Namasudras, and lower Hindu castes.

Blood Groups in Africa

DR. R. ELSDEN-DREW has described the results of an investigation into the distribution of blood groups among African natives (*Pub. S. African Inst. Med. Res.*, 44, Johannesburg, 1939). Tribes were examined over a wide area in Southern Rhodesia, Nyasaland, Tanganyika, Kenya and Uganda, and a number of blood specimens were collected and examined in the field. Considerable differences exist between the peoples investigated, for the percentage of the *O*-group varies from 41 in the Lango to 74 in the Ndau; the percentage of the *B*-group ranges from 5 in the Gogo to 31 in the Ankonde, while the *A*-group ranges from 13 in the Ndau to 32 in the Akamba. The significance of the ethnological distribution of the blood groups is discussed, and it is suggested that the Bantu did not descend from the Negro, but are rather a purer example of a common stock, and that the migration on the west coast has been from east to west rather than in the contrary direction. The Bush people are shown to be less 'ancient' than are the Bantu, and an Egyptian origin is suggested for the Hottentot. The technique employed is described, the findings are subjected to statistical examination, and tables are given of the calculated gene frequencies.

Employment Tests for Rayon Factory Hands

Sigemi H. Kirihara and Kazuo Nakamura (Report No. 41. Japan Institute for Science of Labour) carried out a study to see what relation there was between mental characteristics and efficiency in the operatives of a rayon factory. The ages of the workers ranged from 14 to 18 years. An intelligence test and various performance tests were given to the workers on a number of processes, and the results of the tests were correlated both with the quality and quantity of the output. Intelligence apparently plays a negligible part in success in all processes with the exception of 'reeling'; this process gives a positive correlation with all the tests whereas the others give either negative or insignificant correlations. Taking the results at their face value, the use of tests would not give a better selection than the more usual methods. The writers, however, do not give an adequate account of their method, and although they indicate that motion studies were attempted, they do not make it clear whether the results of such studies guided them in their choice of tests.

A Pleistocene Bird's Egg

Eggs are rarely found in fossil deposits, so that the discovery of a bird's egg on the east slope of Lone Mountain, Nevada, in a deposit attributed to Pleistocene times, deserves notice. Alexander Wetmore states that the egg, of which only one half has been preserved, is embedded in dendritic tufa, having apparently been deposited in water beneath a cone of that material in which it afterwards became involved (*Condor*, **41**, 98; 1939). It measures about 63 mm. in length and 38·5 mm. in width; the shell is pale olive buff in colour on the outer surface and its surface bears irregularly scattered pits. Although no identification is claimed, the author states that comparison with modern eggs suggests that the fossil egg comes closest to the egg of a cormorant.

Jungle Yellow Fever and other Diseases

Important studies on jungle yellow fever in Brazil are described in the annual report for 1938 of the International Health Division of the Rockefeller Foundation, recently published. Jungle yellow fever differs from the classical variety of yellow fever in that it is not conveyed by the mosquito, *Ædes ægypti*. As a result of much research, it seems probable that certain monkeys may be reservoirs of jungle yellow fever, infection from which may be transmitted to man by two species of mosquito. Preventive vaccination with a particular strain of virus has been extensively pursued, more than a million persons having been inoculated, but it is too soon to state with what amount of success. Malaria, influenza, tuberculosis, and worm and other diseases have also been the subjects of study. Details are given upon finance, and of grants made to various bodies, schools and individuals.

A Trypanosome in a Tigress

Parasitic trypanosomes are found in the blood and tissues of various kinds of vertebrates, sometimes causing important diseases in animals, for example, in the horse, and the African sleeping sickness in man. They are, however, rarely found in carnivorous animals, and the record of a trypanosome encountered in a tigress by Dr. Z. Mohamed is therefore of considerable interest (Ministry of Agriculture, Egypt. *Veterinary Service Bull.*, No. 200. Cairo, 1939). The animal came from Sumatra to the Zoological Gardens, Giza, in 1926; it had always been healthy, but became ill on October 18, and died on October 21, 1935. Trypanosomes were found in the blood in large numbers; cultures were failures, but inoculations into dogs, rabbits, rats and guinea pigs proved fatal to these animals in periods of from one to four months. The morphology of this tigress trypanosome is described; it closely resembles that of *Tr. evansi*, which causes surra in camels, but differs from it in some points, and is regarded as a new species, for which the name *Tr. kirdanii* is proposed. The source of the infection in the tigress was not discovered.

Toxicity of certain Insecticides

G. R. Cameron and Cecile R. Doniger have carried out toxicity experiments on mice, rats, guinea pigs and rabbits with lauryl thiocyanate and *n*-butylcarbitol-thiocyanate (in the form of lethane 384). These agents are now being employed as contact insecticides in the campaign against the bed-bug. In field-work, they are diluted, usually with kerosen to about 1 : 64 for the first-named, and 1 : 40 f lethane. Methods of exposure included contact miniature houses sprayed with the undiluted a diluted liquids, skin applications, oral administrati and injections. Both compounds cause death of t experimental animals on injection, but in dilutio similar to those used in field work have produced ill effects, and in such dilutions are unlikely to dangerous to human beings. Undiluted lauryl th cyanate causes severe local reaction when applied the skin, lethane only a slight reaction. The sl should, therefore, be protected when handling t undiluted substances (*J. Path. and Bact.*, **49**, 36 1939).

Effect of Temperature on Chromosomes affected by X-r

K. Sax and E. V. Enzmann (*Proc. Nat. Acad. Sc* **25**, 397–405; 1939) have analysed the effect temperature upon aberrations induced by X-rays the chromosomes of Tradescantia microspores. E cept for earliest prophase, it is found that X-ra induce considerably more breaks at 3° C. than 38° C. There is a critical temperature above whi the number of observed breaks is much reduced, b this critical temperature varies with the season. T authors consider that X-rays induce a similar num of breaks at low and at high temperature, but at hi temperatures the reunion of ends is accelerate therefore the reunion of the original breakage poi may take place. Misalignment may occur throu the slowness of reunion at low temperatures. T reverse temperature effect at earliest prophase difficult to explain, but may be due to similar cau to those underlying the phenomena of chias formation, which also occurs at this stage.

Analyses of Commercial Coals

A report on the analysis of commercial grades coal produced in the Nottinghamshire and Der shire area has just been published (Summary of F Research Survey Paper No. 48. London: H. Stationery Office. 3*s*.). The report forms part of general survey of the national coal resources whi is now being carried out, and is the second to d with commercial sampling in this area. It prese the results of the analysis of 277 grades of coal fr seventeen collieries. The work of the survey proce along two parallel lines. The first deals with t seams as they occur below ground. The coal fr the seams, however, is passed through many proces of blending, cleaning and grading before bei marketed. The second line of investigation is the fore to sample and analyse the actual products of t collieries, so that information may be availa regarding the types of coal actually obtainable consumers. The present report is confined to w of the second kind and deals with such types varieties for the manufacture of metallurgical co high-grade house and gas coals, locomotive a bunker fuels, and free-burning coals for ste raising and general industrial purposes. At ea colliery visited, all the grades finding a commerc outlet were sampled and analysed. Against t recognized commercial name of each grade are giv the screen size and description, including the meth of preparation, use and seam of origin. These d are followed by the analyses. The report also inclu a discussion of the variability of the grades a of the methods by which they are prepared.

ound Vibrations near Dynamite Blasts

THIS has been the subject of investigation by L. Don et (*Bull. Seis. Soc. Amer.*, 29, No. 3, 487; July 39), who has examined in detail the records of such arry blasts obtained on a portable three-component smograph. He found that high-frequency vibrans (25–50) of short duration (about 0·5 sec.) were pical of records on rock, whilst lower frequencies -5) and longer duration (max. 23 sec.) were recorded unconsolidated earth fill, particularly if it exceeded out 20 ft. in thickness. Among the chief types of bration, Rayleigh waves, Love waves and a new bservationally) *C*-type wave were generally obrved. The average period of the Rayleigh waves s 0·14 sec., the velocity of the front of the group out 1,000 ft./sec., and the velocity of the centre of ergy about 800 ft./sec. The period of the Love ves was about 0·15 sec., and the beginning of the oup corresponded roughly with the equation $= 0{\cdot}340 + \frac{\Delta}{2180}$, with t in seconds and Δ in feet. The rd type of surface wave, called *C*, was characterized motion on all three components, with maximum splacements in phase, a pull-down-left followed by push-up-right or other similar combination. It st nearly resembled one of the theoretical coupled ves of Uller. The apparent beginning of the *C* ve approximately fitted the travel-time equation $= 0{\cdot}100 + \frac{\Delta}{2960}$ (ft. sec. units). Its period may ve been 0·18 sec., but irregularity of form made e measurement uncertain. Some or all of these types waves could be identified on the records examined Leet, and their separation by velocity differences s undoubtedly a basic factor in the rapid diminun of the initial amplitudes with distance. It was served that the detailed manner in which this curred was unique for every location, depending on al formations and velocities, but the range of plitudes for various distances and sizes of charge uld be predicted within limits which were narrow ough to be of practical engineering value in timating probable effects on structures. Maximum plitudes at distances greater than a few hundred et from the shots reported (typically 60 per cent d 75 per cent quarry gelatin loaded in three holes in. diameter and 140 ft. deep) did not exceed ¼ and re often less than 1/100 those found necessary to use initial damage to plaster in a test house subted to increasingly severe vibrations until damage curred.

eather Periodicities in Turkestan

PERIODICITIES in weather observed in Turkestan d on the eastern shore of the Black Sea (V. A. agoveschensky, *Piroda*, No. 6; 1939) would appear coincide with the 20-day period of variation which s been found to exist in the solar constant (cf. obot, NATURE, 143, 705–709; 1939). While vestigating the periodicities in daily minimum mperatures, Blagoveschensky discovered in them master cycle, lasting, on the average, 18 ± 2 days, th a sharp fall maintained for 3–4 days at the ginning of each period, followed by a gradual crease until a new period is initiated by another ll. The master cycle may be interrupted on the nth or tenth day by a fall, initiating another mperature wave. These waves occur throughout e year, and the summation of minimum temperares within them shows that there is a more or less regular alternation of relatively warm and cold cycles. They appear to be determined by the passages of families of major and secondary cyclones arriving from the north.

Salts of Europium

ALTHOUGH the rare-earth element europium was characterized by Demarçay in 1900, its compounds have been little studied. H. N. McCoy (*J. Amer. Chem. Soc.*, 61, 2455; 1939) has examined some salts with different results from previous workers. The *m*-nitrobenzenesulphonate crystallizes with 6 (not 3) H_2O, the citrate with 4 (not 5) H_2O and the iodate with 4 (not 5½) H_2O. A number of other europic salts with organic acids, mostly with water of crystallization, were analysed. Europous salts are quickly oxidized by air when they are soluble, but the sulphate, $EuSO_4$, was found to be stable and to suffer little change in a year. An improved titration method is described.

Total Solar Eclipse Results of June 8, 1937

IN "Solar Eclipse Series" No. 1 of the publications of the National Geographic Society (Washington) are described by several specialists the observations of the total solar eclipse of June 8, 1937, made from Canton Island, a small atoll in the Phœnix Islands, by the joint expedition of the National Geographic Society and the United States Navy. The observation of this eclipse presented unusual difficulties, because the path of totality was confined almost wholly to the Pacific Ocean, but the duration of totality, which exceeded 7 minutes—the longest since the year 699—was an incentive to the projected expedition, although no land site was near the position of longest totality. The expedition had perfect weather for the eclipse. The corona was of maximum type according to expectation, the maximum of the 11-year solar cycle occurring in that year. Photographs of the corona were obtained with a special rotating sector disk in the optical train in order that the exposures might be more nearly equalized for the inner and outer parts of the corona. A long streamer was recorded up to a distance of 5 million miles from the sun's limb. The total light of the corona was also determined, and as in most previous eclipses was about equal to half the intensity of the full moon, or one millionth that of full sunlight. A study of the polarization of the coronal light was made, and it was found that the percentage of polarization of the corona and its streamers increased outwards from the sun. The inner corona was also photographed by colour processes (giving a beautiful reproduction in the text). To obtain colour separation negatives, each plate carried its own gelatine colour-filter on the opposite face to the photographic emulsion. A colour painting was also made and is a useful record of the full extent of the corona as seen by the eye. In the study of the spectrum of the chromosphere and of the corona, a new emission line at λ 4412 was detected and appears to be a genuine coronal line. Valuable experience was obtained with a Schmidt camera (giving almost perfect definition over a very wide field) and aluminized plane gratings as applied to eclipse problems. The progress of the eclipse was described from the eclipse camp in a radio broadcast arranged by the National Broadcasting Company of the United States, the radio transmitter being installed on the *Avocet*, the ship which brought the expedition from Honolulu to Canton Island.

THE TEACHING OF MECHANICS

AMONG the many functions which had to be cancelled when hostilities broke out between Germany and Poland was a discussion, due to be held by the British Association at Dundee on September 2, on "The Teaching of Mechanics". This subject holds a peculiar position in the curriculum, lying as it does in the region between physics and mathematics, and having the character both of a severely academic subject and of a cultural one.

The opener would have been Prof. E. A. Milne, who proposed to consider the teaching of the subject to schoolboys, undergraduates, and research workers in turn; in the first stage, experiment should be dominant. It is not surprising, in view of Prof. Milne's own work and experience, that he should suggest that in the third stage, the tacit assumptions of the existence of rigid bodies and of the uniform flow of time should be subjected to criticism. He also offers the suggestion that the logical unsatisfactoriness of quantum mechanics may be due to want of interest in the foundations of mechanics among those who work on the subject.

With Prof. Milne's views we may compare those of Prof. R. Peierls, who was to have been the closing speaker, and who remarked to the present writer that he was sufficiently new to the task of teaching mechanics to feel an interest in its problems and technique. He finds it difficult to steer a true course between the Scylla of special examples and the Charybdis of general theorems, and he feels also that 'statics-and-dynamics' takes up too much time, to the exclusion of elasticity, hydrodynamics and even electricity and optics. On detailed points, he would like to see more use made of dimensional arguments, and the asymptotic solutions of problems (a plea which the writer heartily supports), whilst Prof. Milne stresses in particular the value of vectorial methods as developed by S. Chapman.

The two papers to have been given between these were both by teachers in schools. Mr. K. S. Snell, of Harrow, feels that in the general introduction, to be taken by all boys, experiment should be fundamental, and the appeal to phenomena of daily life should be frequent. This introduction would thus satisfy those who demand cultural value in the subject. For the other course, to be taken afterwards by boys who intend to specialize in science subjects, Mr. Snell feels that the order should be reversed, the subject being developed mathematically, and the deductions checked by experiment. This is, of course, the line followed in much of the historical development of the subject, and allows far fewer principles to be used than the alternative method where experiment is made basic at each step.

It was fitting that at a meeting held in Dundee one of the speakers should represent Scottish schools, and this role was filled by Dr. G. P. Tarrant, of Edinburgh, who, in addition to suggesting methods of teaching, had some specific grievances to mention. He points out that the content of Scottish education has failed to adapt itself to the modern world as rapidly as has that of England. Science there is still tolerated rather than encouraged, so that in the Higher Certificate examinations, Latin or geography or history or book-keeping or art is a whole subj but physics or chemistry or biology is a half subj Naturally the school course is designed to meet examination requirements, and it becomes necess to teach 'electricity' without mentioning elect magnetic induction, motors or moving-coil inst ments and thereby deprives the subject of any va to the boy who does not specialize later. In mecha itself, the syllabus omits the laws of momentum any consideration of rotation, and even exclu simple harmonic motion from its consideration kinematics. In fact, the Scottish pupil does ab half the science subjects, and does each of them ab half as thoroughly as the English pupil. Hence p of Dr. Tarrant's address would have been devoted a plea for overhauling the scheme of teaching a examining science subjects in Scotland. The pres writer would, however, remark that Scotch engine are known all over the world as sound and relia men in general, and therefore that it would se desirable to consider (*a*) whether mechanics is l important to engineers than teachers believe, (*b*) whether mechanics can easily be learned later life, in which case the school syllabus is less import to future specialists than we have assumed.

The other part of Dr. Tarrant's address show how, in spite of difficulties, mechanics can be m a 'live' subject. By means of Meccano models roof trusses and the like, problems of moments c be visualized, and the difficulties of three dimensi removed. The same method illustrates the trian of forces clearly and visually. When the stage calculation is reached, the human being makes interesting subject. It requires no difficult mat matics, for example, to show on mechanical princip that the requirements for the high jump are: (1) lo legs; (2) powerful swing with the free leg and w the arms, while the take-off leg is still bent; (3 straightening of the original forward tilt of the bo then a straightening of the take-off leg, and fina a jump with the toe, the whole being so timed th the arms and legs acquire their upward moment before the lift of the centre of gravity commenc and so that they are brought to rest relative to t body at the exact instant that the toe leaves cont with the ground; (4) a style of crossing the l which keeps the centre of gravity very low on t bar and the head above the buttocks. Like Pr Peierls, Dr. Tarrant introduces the dimensio argument, and uses it, for example, to show tha very small animal needs relatively more food th a big one, merely to keep warm, and explains the fore why small animals are not indigenous to t arctic or antarctic regions.

Had the meeting taken place, it was the hope the organizers that the contributions to the f discussion following these papers would have be not the least valuable part, but it is hoped that t slight outline here given of the contents of some the papers may at least stimulate those who wo have discussed the matter, to consider it again themselves and perhaps to try out different metho of teaching, the results of which can be reported a more suitable time. J. H. AWBERY.

CRITICAL AND CO-OPERATIVE PHENOMENA

N 1937, Prof. J. E. Lennard-Jones and Dr. A. F. Devonshire published two important papers on ritical Phenomena in Gases" in which they re-rded each atom of a dense assembly, irrespective physical state, as moving in the field of force of neighbours and confined by them to a small gion of space equal to the mean available volume r atom. The methods and theory of these papers ve now been extended in two further papers.

The first[1] deals with a theory of melting and the ructure of liquids. From X-ray evidence on liquids is concluded that there exist regions of order proximating crystallinity, particularly just above e melting point, and from X-ray evidence on alloys is known that certain types of disorder can occur. is therefore difficult to differentiate the crystalline id and liquid states satisfactorily, and this is cessary before any theory of melting can be veloped. Assemblies of atoms with spherically mmetrical fields of force probably form 'normal' uids. In a solid the cell in which an atom moves localized, whereas in a liquid the motion of an om must be represented as a vibration about a int which is itself undergoing displacement. Solids assumed to be alloys of atoms and 'holes'. At low temperatures the atoms occupy all the available sites on a perfect lattice and the 'holes' all the available sites on a similar lattice which interpenetrates the first. The number of atoms occupying abnormal sites gives a measure of the disorder of the assembly. The energy required for the interchange of an atom and a 'hole' is assumed to be a function of the volume of the whole assembly. From these concepts a theory of melting is developed. An equation of state of solid and liquid is also derived which gives values in good agreement with observed values for change in volume on melting, and for the thermal expansions of solid and liquid.

The subject-matter of the second paper[2] is very similar. The method in the former paper is simplified by assuming that the environment of any one atom is governed by the average state of order throughout the assembly, instead of, as in the former paper, taking account only of immediate neighbours of any atom. The equation of state of a disordered assembly, the melting temperature in terms of interatomic forces, and the various phenomena associated with melting are discussed.

THE ENGINEER AND THE STEELMAKER

T is of great importance that the steelmaker should know all about his products, so that he may e advice to the engineer as to any of the alloy els that he manufactures.

Mr. D. Taylor, in the *Journal of the Junior stitution of Engineers* of October, in a paper on teel and the Engineer", lays stress on the impor-nce that the steelmaker attaches to providing the st suitable quality of steel for the work which e engineer has in hand. The common sphere of tivity linking together the work of engineers and tallurgists is the main subject of the paper.

The author gives some typical examples of a tallurgical and mechanical nature and of wrong ndling which leads to failure. He traces what ppens to a 'cast' of steel from its initial stages its final release. The first important stage is ecting the raw materials, the next the method of lting, which governs the cost, and finally the mputation of the 'mixes' employed. Five methods melting are used. The first method is the crucible thod, in which the furnace is of simple design and ily controlled. The second is the Siemens open arth furnace, which produces either acid or basic el. In the case of acid steel, the bath of metal is rked under an acid slag and so the sulphur and osphorus are not thereby eliminated and purer terials must be used. In the case of the basic thod, the sulphur and phosphorus may be removed nost entirely, while the carbon and manganese ntent are practically unchanged. The third method the arc furnace run with a basic hearth. The duct is low in sulphur and phosphorus, and this is good from the mechanical point of view. The fourth method is the coreless high-frequency induction furnace. The advantages of this furnace are that there is no contamination of the metal bath, due to fuel; the bath is in constant motion during melting; the melting temperature can be controlled within certain limits and the bath can be refined. Another method used is to employ an open hearth furnace to do the heavy melting, and then to refine the metal in the electric furnace.

The product of the furnace is required either in the form of castings or as ingots. The ingot is a casting of a particular type which is later mechanically worked. It is important that the ingot should be as perfect as possible, otherwise defects will arise at a later date. If it is to be sound, careful control of the casting temperatures must be taken. To produce a perfect ingot the surfaces should be smooth planes with correctly rounded corners. Prior to use, the inner surfaces of the mould are prepared by painting with a special compound. After the metal has been poured into the mould, it commences to freeze in planes parallel to the ingot mould surfaces. During the freezing, any non-metallic matter will, as crystallization proceeds, be rejected and conveyed to the centre of the ingot, which is the last portion to freeze, and is thus trapped. When the steel has solidified and cooled, it can be stripped from the ingot mould. It is immediately marked up with its cast number, which identity it carries throughout the works. Many months after casting, relevant data, such as casting temperature, nature of the ingot skins, etc., of the cast can be readily found by reference. In this way the steelmaker builds up a personal knowledge and experience of the casting made by various alloys.

If the product of the furnace is required in the form of castings, the casting temperature must have its definite value. In this case its contours are good, the shrinkage is a minimum, the structure is reasonably strong and free from blow holes. The author gives lists of the common defects associated with castings and also defects rising from incorrect treatment or application.

The engineer sometimes produces components which need to be heat-treated. The hardening sho has a great deal of responsibility, as it is the la stage of the work. The steelmaker goes to a grea deal of trouble in determining the critical points c his alloys, which can be found from the heating an cooling curves, and from these he computes the be temperatures for hardening. These temperatur must always be used. The pyrometer must b periodically inspected and calibrated. Useful inform tion can often be obtained from the microstructu as seen by microscopic examination of a represent tive sample by means of a metallurgical microscop

---

NUCLEOLI, SATELLITES AND SEX CHROMOSOMES

By Prof. R. Ruggles Gates, F.R.S.

In recent years striking discoveries have been made regarding the origin and history of the nucleolus. It has come to be recognized that in every cell of a plant or animal species there is at least one pair of chromosomes which is specially concerned in producing this body. This pair of chromosomes may have either a satellite or a secondary constriction. In a satellited chromosome the exact point of origin of the nucleolus appears to be the end of the chromosome proper, where the delicate thread or filament arises which attaches the satellite (a tiny globule of chromatin) to the body of the chromosome. This locus has been called the nucleolar organizing body. In the telophase of mitosis each satellited chromosome gives rise to a nucleolus, while in a chromosome with a secondary constriction the nucleolus arises at the constriction.

There are thus in the early telophase of mitosis as many nucleoli as there are chromosomes with satellites or secondary constrictions (the primary constriction being at the spindle fibre attachment). Some chromosomes with a secondary constriction, however, do not produce a nucleolus. By the following prophase the nucleoli have frequently all fused into one. By means of a new stain[1], Feulgen and Light Green, which stains the chromatin (including the thread or filament) red and the nucleoli green, the exact nature of the attachment of nucleolar chromosomes, whether at a satellite thread or a secondary constriction, can easily be determined. The number of chromosomes attached to the nucleolus in prophase is thus the same as the number which produce nucleoli in telophase. This relationship can generally be confirmed by an examination of the chromosomes in metaphase, when the number which have satellites or secondary constrictions can be determined, except in the very smallest chromosomes.

In an ordinary diploid plant or animal species there is thus one pair of chromosomes with satellites, or sometimes with secondary constrictions instead. This difference seems to depend merely on whether the thin portion (thread) of the chromosome is near the end, to produce a satellite, or nearer the middle of the chromosome. In polyploid species the number of *SAT*-chromosomes and telophase nucleoli is correspondingly increased. Thus a tetraploid will have four, and a hexaploid species such as the bread wheats will have six.

Some species, however, which have hitherto be regarded as ordinary diploids, have two pairs nucleolar chromosomes. Sometimes one of the pairs has satellites and the other pair seconda constrictions. Some of these cases are clearly seco dary tetraploids in which a new species or perhaps new genus has arisen through a change in the ba number of chromosomes. Many such cases have be observed in connexion with recent cytological wo The study of the nucleoli in a species has thus beco a method of tracing changes in chromosome numb and how they have taken place, in other wor nuclear phylogeny.

As an example, rice may be cited. Cultivated ri *Oryza sativa*, has twelve pairs of chromosomes. B many varieties have two pairs of nucleolar chrom somes, indicating that it is a secondary tetraploid or amphidiploid. Further evidence is afforded by t secondary pairing of the chromosomes in the poll mother cells. Such a pairing of chromosome pairs bivalents with each other indicates a specific attra tion, which is the result of homology.

The bivalent chromosomes arrange themselves in r so that the maximum association is into two grou of three bivalents and three groups of two bivalen 2(3) + 3(2) or *AAABBBCCDDEE*, thus making fi groups of chromosomes having different homologi That five is the basic number of chromosomes, fro which the twelve in rice has been derived, w confirmed by showing (Ramanujam[2]) that in certa genera related to Oryza, such as Zizania a Lygaeum, the chromosomes were in high multiples five, while in other genera, such as Hygroryza, th were in multiples of twelve.

Many varieties of rice still have two pairs *SAT*-chromosomes, and so produce four nucle confirming that they are secondary tetraploids. B it appears that it is only necessary for an organi to have one pair of *SAT*-chromosomes in or for the cells to function. In many varieties of r only one pair is present. The other pair has be lost, probably by a mutational loss of a satellite fr one of the four *SAT*-chromosomes and subseque inbreeding. Several other wild species of Oryza, bo in India and Africa, have doubled their chromoso and have 24 pairs. They are thus secondary oc ploids. This is an example of the way in which t origin and history of a genus can be traced vestigation of the behaviour of the chromosomes and pecially of those which produce nucleoli. There is uch other evidence that five is the fundamental romosome number in the grasses, the family to hich rice belongs.

Another recent example may be taken from the guminous genus Cicer (Iyengar[3]). *C. arietinum* has chromosomes. In prophase four chromosomes are tached to the nucleolus and at meiosis the maximum sociation is one group of three bivalent chromo mes, two groups of two and a single bivalent, 3) + 2(2) + 1 or *AAABBCCD*. This indicates at four different (non-homologous) chromosomes as the original basic number. These observations nfirm much other evidence (some of it unpublished) at four is the basic or original number of chromo mes in the family of Leguminosæ, from which all her numbers in this family have been derived.

It is now well known that in groups of organisms as dely separated as insects and liverworts there are nerally sex chromosomes, typically a large *X*- and small *Y*-chromosome. Moreover, these bodies or rtions of them are heteropycnotic, that is, they are ndensed in prophase when the other chromosomes e still in a diffuse condition. The heteropycnotic rtions are believed to be genetically inert.

While the *XY* combination in insects, mammals d some other animals produces a male, in liverworts d mosses the *XY* pair are present in the sporophyte, e male gametophyte having a *Y* and the female metophyte an *X*, in addition to the remainder of e haploid set of chromosomes.

Recent observations show that in many cases, both insects and bryophytes, the *X*- and *Y*-chromosomes e attached to the nucleolus, that is, they have a tellite or secondary constriction and are concerned producing the nucleolus to which they are attached. e possible significance of this widespread condition pears to have been overlooked. Kaufmann[4] has own that in somatic cells of male *Drosophila lanogaster* the *X* (with a secondary constriction) d the *Y* (with a satellite) are attached in prophase the nucleolus which they produce. Heitz[5] indicates e same situation not only in *D. melanogaster* but o in *D. funebris*, *D. simulans*, *D. virilis* and *D. ydei*. By its heteropycnotic condition Heitz identi s the *X*-chromosome as attached to the nucleolus o in *Scatophila unicornis* and in two other genera insects.

Thus it appears that in these insects the *X*- and -chromosomes are generally nucleolar chromosomes, e former with a constriction and the latter with a tellite. An exception was found, however, by ufmann[6] (1937) in *Drosophila ananassae*, in which e *X* is not nucleolar, but a pair of autosomes dinary chromosomes) with satellites are attached the nucleolus in the female. In the male, however, ere are three chromosomes attached to the nucleolus, e *SAT*-pair and the *Y*, which also has a satellite. ufmann suggests that this departure from the ual condition has been produced in this species by translocation between the *X*-chromosome and an tosome.

From a study of the salivary gland nuclei of Droso ila, Frolova[7] finds the nucleolus attached by a anched chromatic thread to the chromo-centre, to ich the ends of all the chromosomes are in turn ached. It seems probable that the sex chromo mes have here become detached from the nucleolus ich they presumably produced, as in less specialized ds.

In liverworts, Lorbeer[8] (1934) figures a large *X*-chromosome, evidently with a secondary constriction, attached to the nucleolus in *Sphaerocarpus Donnellii*, in the cells of the female thallus. In the cells of the male thallus there is a very small *Y*-chromosome and also an autosome with a satellite. In the spore mother cell there are seven pairs of autosomes together with a large heteropycnotic *X*-chromosome attached to the nucleolus and the very small *Y*, also no doubt attached to the nucleolus when in its natural position. In *S. europaeus* the cells of the male thallus contain a *Y*- and a *SAT*-chromosome, while in the female gametophyte an *X*- and a *SAT*-chromosome are present. In Marchantia, both the *X* and the *Y* are figured attached to the nucleolus. Thus it appears that the sex chromosomes of the liverworts are nucleolus-producing, as in insects, but there are in some species also a pair of autosomes which produce nucleoli.

Allen[9] figures in *Sphaerocarpus cristatus* a heteropycnotic body which is part of the *X*-chromosome, attached to the nucleolus. In the liverworts *Pallavicinia longispina* and *Calobryum rotundifolium*, Tatuno[10] figures a large *X*-chromosome with a secondary constriction and a smaller *V*-shaped *Y*, both being shown attached to the nucleolus in the spore mother cell of Pallavicinia. In *Makinoa crispata*, on the other hand, there are no heteropycnotic (sex) chromosomes, but the cells of the sporophyte show a pair of *SAT*-chromosomes. Tatuno[11], in a further study, shows a large heteropycnotic *X* and a small *Y* in *Pallavicinia Lyelli*, *Riccardia pinguis*, *R. blasioides*, *Pellia Neesiana* and *P. Fabbroniana*. But in both species of Pellia a *SAT*-chromosome is figured during mitosis in both the male spores (which have the *Y*) and the female spores (which have the *X*-chromosome).

In mosses, similar conditions hold. Shimotomai and Koyama[12] (1932) show in the female gametophyte of *Pogonatum inflexum* a large heteropycnotic *X*-chromosome attached to the nucleolus, a small *Y*-chromosome attached in the nucleoli of the male gametophyte, and both attached to the nucleolus in the cells of the seta (sporophyte). Shimotomai and Kimura[13] show similar conditions in Polytrichum and Ceratodon.

Thus it appears that both in insects and bryophytes the sex chromosomes take part, with or without a pair of autosomes, in forming the nucleoli. In diœcious flowering plants the relation of the *X*- and *Y*-chromosomes to nucleolar production is not yet known. By the use of the new staining method already mentioned, it will be possible to trace their history fully in flowering plants and also to throw further light on the behaviour of the sex chromosomes in other organisms.

SCIENCE NEWS A CENTURY AGO

The Geological Society

At a meeting of the Geological Society, on November 6, 1839, several papers were read, among them being one "On the Relative Ages of the Tertiary and Post-Tertiary Deposits of the Basin of the Clyde" by James Smith; and another paper was "On the Noxious Gases Emitted from the Chalk and Overlying Strata in Sinking Wells near London", by Dr. Mitchell.

The most abundant deleterious gas in the chalk, said Dr. Mitchell, is the carbonic acid, and it is said to occur in greater quantities in the lower than the upper division of the formation. The distribution of it, however, in that portion of the series is very unequal, it having been found to issue in considerable quantities from one stratum, while from those immediately above and beneath none was emitted. Sulphuretted hydrogen and carburetted hydrogen gases sometimes occur where the chalk is covered with sand, and London clay, as well as in other situations. In making the Thames Tunnel they have been both occasionally given out, and some inconvenience has been experienced by the workmen: but in no instance have the effects been fatal. In the districts where sulphuretted hydrogen gas occurs, the discharge increases considerably after long-continued rain, the water forcing it out from the cavities in which it had accumulated. Dr. Mitchell cited several cases of well-diggers having been suffocated from not using proper precautions.

Difference of Longitude between Greenwich and New York

At the Birmingham meeting of the British Association in August, 1839, Edward John Dent (1790–1853), the well-known chronometer maker, gave an account of observations made with four chronometers sent to the United States and back in the S.S. *British Queen* on her first trans-Atlantic passages.

Referring to the use of chronometers, Dent said that "The rapid transmission of chronometers now practicable by means of steam vessels from one meridian to another offers great facilities for the determination of the differences of longitude". On November 8, 1839, he wrote from No. 84, Strand, to the Editor of the *Athenæum* giving particulars of observations made during the second voyage of the ship with a second set of chronometers. By the second experiment the difference of longitude between the observatory at Greenwich and the City Hall, New York, was found to be 4h. 56m. 0·24s. west. "The great rapidity and accuracy," said Dent, "with which this important branch of nautical inquiry may be pursued over the whole surface of the globe, as the agency of steam shall be extended, is now, I think, demonstrated. . . . Within the space of ninety-nine days, we have seen the *British Queen* carry chronometers *four* times across the Atlantic, and give ample time during each of her visits to New York for the necessary observations of rates, etc.

"All objections founded on the idea that the motion of a steam vessel would affect injuriously the more delicate movement of the chronometer and taint the results must now fall to the ground. In the two voyages out and home of the *British Queen*, no derangement occurred, and the determination of the longitude of the far-distant ports she sailed between is, probably, settled for ever, within a fraction of a second of the truth."

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned:

Municipal Engineer to the Municipality of George Town, Pena —Petroe and Williams, 1 Victoria Street, S.W.1 (November 7).

International Senior Fellowship in Science—The H Secretary, British Federation of University Women, Ltd., 16 K Street, Reading, Berks (November 10).

Borough Electrical Engineer and Manager to the Com Borough of Halifax—The Town Clerk, Town Hall, Halifax (Nov ber 14).

Research Professor of Medical Psychology in the Univer of Queensland—The Agent-General for Queensland, 409 Strand, W. or the Universities Bureau of the British Empire, 88a Gower Str W.C.1.

Senior Technical Officers (Ref. 875/Y) and Technical Offic (Ref. 875/Z) by the Air Ministry—The Under-Secretary of St S.2.A., Department Z.A., Air Ministry, Adastral House, Kingsw W.C.2.

Part-time Lecturer in Physics—Head of the Department Mathematics and Physics, The Polytechnic, Regent Street, W.1.

Temporary Meteorological Assistants (Male) in the Meteo logical Office—The Under-Secretary of State, S.2.B (Met.), Departm Q.J., Air Ministry, Adastral House, Kingsway, W.C.2.

PHYSICAL ANTHROPOLOGY AND PROBLEMS OF MODERN SOCIETY

WHEN it became necessary during the European War of 1914–18 to assess the ysical development and capacities of every man military age in the British Isles, certain facts ierged which caused no little consternation hen they were revealed at a later date. An duly and unexpectedly large proportion of rolled men were found to be physically unfit r the more strenuous forms of active service, d many, indeed too many, incapable of any rm of military duty abroad. Yet it may be ted that by August 1914, legislation for the edical inspection of school children—the only rge-scale provision for the accumulation of idence relating to the physical condition of the pulation of Great Britain—had been in force r seven years; and more than one medical officer r education had directed attention in his reports whole areas in which a relatively poor physique d under-development pointed to a probability of ironic malnutrition and adverse social and onomic conditions. Had these warnings not en ignored, it would have been unnecessary to int out for the benefit of those who expressed strongest terms their surprise and consternation the results of this, the first, approach to some-ing in the nature of a physical census of a con-derable proportion of the British population, that this instance, if ever, the child might be regarded indeed 'the father of the man'. Study of what e child was known to have been would have counted surprise at the man he had become.

Anthropologists had urged strenuously, but ithout avail, the inclusion of anthropometric servations in the provision for medical inspec-n of school children. They were in consequence rhaps a little less perturbed than some by these revelations of the apparent physical inadequacy of the population. Although recognizing the gravity of the situation, they also realized that in the absence of a norm, a properly adjusted standard of physical development according to type, the crude facts as stated lost half their force in argument. A national standard, or an ideal standard, such as the regulation stature and chest measurement required in the recruitment of a peace-time army of picked men, had been applied to a mixed population without regard to the racial differences, which constitute the most striking feature in the physical characteristics of the British population. The same criticism applies to the statements as to under-development among children, in which a general standard correlating age with development is applied without knowledge of the norm in terms of racial differentiation. Obviously the norm of the tall fair Nordic of East Anglia is inapplicable to the short Mediterranean type of the West, yet the short dark operative of the industrial north of England has been characterized as stunted by generations of factory life, without inquiry or knowledge as to the capacity for development of the type in optimum conditions.

The great enthusiasm for the application of scientific method to the study of social and economic problems, and the application of the results in ameliorative action, in the years following on the War, in great measure seems to have passed the anthropologist by, at least so far as concerns the study of the population of Great Britain. Perhaps the anthropologist himself is to blame, and in default of a clear and concrete statement of the application of his studies addressed to the public as well as to those who control the strings of the purse, but are nevertheless swayed by the trend of public opinion, the study of the racial characters of the population and their distribution must seem academic and remote from reality. Even the arguments of the eugenist, convincing as they may seem to the initiated, lose force when confronted with a demand for a definition of the type towards which eugenic control and conscious selection—for that is what it amounts to—would work, while in the references of its opponents to such approaches to a standard as have been attempted, eugenic studies are frankly twitted with being 'class-conscious'.

Happily it is no longer possible to say that physical anthropology is in default of a re-statement of the possibilities of its aims and methods in relation to the social and economic problems of a modern and—it is unfortunately increasedly apposite to say—post-War society. The due and proper function of the scientific study of these problems, which insistently demand remedy, and will demand it with still more urgency in the social reconstruction which must follow inevitably on the present interruption and disintegration of normal life, is set forth with admirable lucidity in the presidential address delivered before Section H (Anthropology) at the recent Dundee meeting of the British Association, from which extracts are given on another page of this issue of Nature (see p. 804). It is unnecessary to repeat here the list of inquiries in which Prof. Le Gros Clark holds the co-operation of the anthropologist essential; but bearing in mind what has been said of the racial and regional differences in the British population, the need for a survey of the physical characters of the people, in their regional distribution, of which he indicates the purpose, cannot be too strongly urged. It is an essential preliminary to all valid testimony in inquiries related to the assessment of the physical development of the population of Britain in its many phases.

It is remarkable and by no means creditable to Great Britain as a nation, professing to have regard to scientific methods, that for data relating to problems of growth, on almost every point, we must turn to evidence recorded in the United States of America. Yet as was shown by the valuable research by Miss R. M. Fleming among school children in Wales over a period of years, such observation is not only of signal importance in its bearing upon questions of purely scientific interest, for which data are lacking though the raw material is at our doors, but also it is a crucial index to a number of problems fundamental in testing the physical welfare of the communit and in pointing the way to remedial measur Thus in the course of the meeting of the Briti Medical Association in Aberdeen in July last, I Alexander Low submitted an analysis of t anthropometric measurements of more than thousand infants born in the Aberdeen Materni Hospital, of whom also fifty males and fifty fema were re-examined annually up to the age of fi years. From the figures it emerged that these infa were 5–6 ounces heavier at birth than those sho in the published figures for other towns; that af the second year the rate of increase was somewh greater for girls, so that at the fifth year the gi were slightly superior in weight to the boys; th in height at birth both sexes were somewhat und the usually accepted figures, but that at five ye these children were more than an inch taller th Edinburgh and Dundee children.

The regional differences may be noted. Yet default of fuller knowledge, the only suggest bearing on the question of the relative increase height which was put forward was the efficien of the Aberdeen working-class mother, and h appreciation of the educative value of the chil welfare centre. Whether this is the real a only explanation, without the further knowled of the facts, which is not available, it is impossi to say, but it makes all the difference to a attempt at ameliorative measures. If the regio variation is due to heredity and not environme it must be accepted that in all probability a attempt to raise the standard for this one cha acter, provided others show no marked a obvious deficiency, will be largely wasted effo As Prof. H. A. Harris pointed out in the d cussion of Dr. Low's communications, we kn more about the embryology and growth chickens and rats than about humans. At prese Dr. Low's continuous series of measurements unique for Great Britain, yet, as he argued, concerns a period of the highest importance f the welfare of the individual.

Reference may also be made to Dr. H. Bathu Norman's investigation (see Nature of Sept. 1 p. 518) of the figures relating to the developme of adolescents between the ages of thirteen a eighteen years in a public school and in seconda schools in the county of Durham, with the view arriving at a norm of development in optimu conditions. While the secondary school boys we homogeneous in respect of regional origin, an therefore, it may be presumed, predominantly form physical type, it is an equally justifiable umption that the group of public school boys mined constituted a mixed population. The ortance of the distinction is to be seen in the clusion. In every one of the characters investi- ed the advantage lies on the side of the public ool boy, for which superiority in nutrition is d to account. In regard to stature, however, ile some influence is conceded to heredity, that racial history, it is inferred that deficiency in rition and environmental conditions has pre- ded attainment of the full development of ich the organism was constitutionally capable— easonable and probable inference, which cannot tested, nor if correct, can the degree to which individual falls short be measured in the absence of any knowledge of the regional or racial type norm for these ages in either class.

Admirable as is Prof. Le Gros Clark's statement of his case, these investigations by Dr. Low and Dr. Norman should clinch the arguments of the physical anthropologist as to the urgency of the need of an extended knowledge of the physical characters of a population of so mixed a character as that of the British Isles. It is not only of academic interest to the man of science, it is also fundamental to full understanding of the many adverse nfluences which mitigate against the building up of a healthy population, developed to capacity, which will be one of the more pressing needs when we turn to repairing the ravages of war.

STATISTICS IN THEORY AND IN PRACTICE

Principles of the Mathematical Theory of rrelation

A. A. Tschuprow. Translated by Dr. M. ntorowitsch. Pp. x+194. (London, Edin- gh and Glasgow: William Hodge and Co., Ltd., 9.) 12*s*. 6*d*. net.

Methods of Statistical Analysis

C. H. Goulden. Pp. viii+278. (London: pman and Hall, Ltd.; New York: John Wiley Sons, Inc., 1939.) 17*s*. 6*d*. net.

THE original German edition of Tschuprow's book on the theoretical foundations of relation between two variables is probably not well-known among English readers as it might and we are therefore grateful to M. Kantoro- sch for this translation. Tschuprow (Russian tistician, 1874–1926) was interested in corre- on partly from the fashion of his time, and tly from his interest in social science; but his rpretation of the word is a wide one, and many es of stochastic relation are discussed.

'schuprow was roughly contemporary with the glish school of statisticians led by Karl Pearson, acknowledges the close association between own treatment and the results of this school. se familiar with the more recent work of R. A. her and others on small-sample theory will l some of the approximations reached in pter vi superseded by exact methods, a biblio- phical reference (p. 192) to Fisher's work on mal correlation, and a note (p. 183) by the nslator on English statistical literature, helping close this gap.

Formulæ independent of the population sampled are, however, still of more than historical interest, and it is instructive to see how far Tschuprow was able to go with his theoretical methods; note, for example, his correct surmise on p. 112 that the average value of the criterion χ^2 ($N\varphi'^2$ in Tschuprow's notation) is $N(k-1)(l-1)/(N-1)$ for a $k\times l$ contingency table. The mathematics throughout are not advanced; moreover, all details of the derivations are relegated to an appendix.

Before the more technical chapters dealing with population parameters and sample estimates of them (*a priori* coefficients and empirical coefficients) there are some sections on the meaning of correlation, including a careful distinction between correlation and causality. There is much common sense, too, percolating through the concluding chapter on the object of correlation measurement. The final remarks of all are so pertinent that they are worth quoting in full:

> "It is not enough to be familiar with the technical tools; he [the statistician] must be familiar with the subject of the investigation as well, and he must have complete command of his material. He must possess the ability to adapt the technique of his investigation to the end pursued and to the possibilities before him. A routine-like mechanical reliance on ready-made prescriptions leads, even when the most complicated formulæ are employed and the most precise calculations are carried out, to an unproductive waste of time and energy and to the accumulation of numerical values which are but little likely to enrich our essential knowledge."

(2) The second book under review has been written for research workers requiring practical knowledge of statistical methods, and will in particular prove a very useful and comprehensive work for those engaged in agricultural experimentation. There are already other books of similar character, but Goulden has the advantage of being one of the most recent authors in this field, and has been able to incorporate practically the whole of the modern statistician's equipment.

The chapter on the field-plot test contains a summary of the new methods of testing a large number of varieties, developed by F. Yates, and will be welcomed by many workers; it should be noted that the quasi-Latin square design is not mentioned. The rest of the book is fairly standard to one familiar with Fisher's own statistical works, and includes, for example, chapters on goodness of fit, correlation and regression, and analysis of variance and covariance. In the chapter on non-linear regression, where the author uses Fisher's technique in his treatment of orthogonal polynomial fitting, he might have distinguished between the method of orthogonal polynomials in c fitting and the summation method of fin moments. At the end of each chapter are e cises which are a potential source of value to thorough student.

Among minor details, the indiscriminate us p. 80 of both b_{12} and $b_{12\cdot 3}$ for a partial regres coefficient is confusing. The meaning of the on p. 81 is peculiar to this book. The last fi in the first paragraph of p. 72 should be 0· not 0·75. The standard error of a mean does seem too well discussed (p. 12 and p. 115).

Both Tschuprow's and Goulden's books are statistical technique; though one is theoreti the other practical. Their common philoso however, is the intimate relation between us theory and useful practice, so that in spite of difference in the authors' interests, there is recommendation that can be made for either w namely, that it should help its reader to acq a sound grasp of the true function of statistic

M. S. BARTLETT

PHYSIOLOGY OF INSECTS

The Principles of Insect Physiology
By Dr. V. B. Wigglesworth. Pp. viii+434. (London: Methuen and Co., Ltd., 1939.) 30s. net.

THE most significant change of outlook among entomological workers to-day is the increasing appreciation of the importance of the physiological aspects of their subject. These same aspects are also drawing an increasing number of young zoologists in their search for problems upon which to expend their energies. A great literature already exists on insect physiology, and it is appearing in a disconcertingly wide and erratic range of journals. The consequence has been that keeping up to date with this literary growth has already transcended the possibilities of most entomologists, and Dr. Wigglesworth's book has made a timely appearance in consequence. With evident critical powers and acumen he has done the great service of co-ordinating and sifting out this great accumulation of data and facts and welding it as a whole into a really indispensable text-book. At the same time he has incorporated the results of his own researches, which are distinguished for their originality and for the resourcefulness of the technique that has been used. The general anatomy of insects is outside the programme of this book, and is only dealt with in so far as it may be necessary to make the physiological arguments intelligible. Histology the other hand, naturally comes in for fuller tr ment since it is intimately linked up with interpretation of the functions of organs and pa It is coming to be recognized that rational meas for controlling injurious insects are often depen upon a proper acquaintance with the physiolog 'make-up' of the species concerned. As Wig worth remarks, knowledge of the ecology of insect is necessary in order to achieve effec control, while ecology itself can only be prop appreciated in the light of an understandin physiology.

The book is divided into fifteen chapters, e being fully documented with its own bibliogra The relative merits of different chapters are h to assess individually owing to the general stand of excellence of the book as a whole. It is, howe probable that few readers will dispute Chapter iii is a masterly outline of the phenome of growth and that Chapter i, on developm within the egg, is possibly too short and sket to be as useful as it might have been. Errors omissions are pleasingly scarce. A few mispri such as *Menanopus* (p. 327) and *Cioneus* o (p. 319), are trivial faults, while the statem about the effects of change of diet in the after the second day (p. 60) is probably a *la* *calami*.

T. Wigglesworth is to be congratulated upon ing written a work indispensable to all serious dents of entomology. It will also be used a l deal by the general zoologist and by the parative physiologist. Destined to rank as a ndard treatise and become also a working handbook, we look forward to its having a long lease of life, and passing through many editions. It is not likely to have any serious competitors for a long time to come. In the next edition an index of authors would be a great advantage.

A. D. Imms.

THE STORY OF PLAGUE AND OTHER TROPICAL DISEASES

History of Tropical Medicine
ed on the FitzPatrick Lectures delivered before
Royal College of Physicians of London, 1937–8.
H. Harold Scott. Vol. 1. Pp. xix + 648 + 3
tes. Vol. 2. Pp. iv + 649–1165 + plates 4–13.
ndon : Edward Arnold & Co., 1939.) 50s. net.

HESE volumes contain a history of tropical medicine, using that term in its ordinary e sense. Starting with the Navy and Mercantile rine, they tell of the dreadful conditions in ch seamen lived a hundred and fifty years ago, ther in or out of the tropics, and the still se quality of the men haled into the Navy the press gang, so bad indeed that it was not canity but their quality, their cost, and the ct on the nation that brought pressing to an just over a hundred years ago. The steady ance in the Army's health in the last hundred rs comes out strongly, and the same lesson is n in the chapters on the Colonies, Protectorates d Dominions, and on India. The main part of book is taken up with disease caused by anisms and food; and the chapter on plague an excellent example of its scope and outlook. Vhen the Philistines captured the Ark from el, and when thereafter mice began to mar ir land and its people to die of swellings about secret parts, they sent back the Ark with, in golden images of these two things they corted. On the other hand, the great plague of iens in 430 B.C. may, Scott believes, have been lioidosis, since Thucydides, who himself recered from it, mentions no buboes. Again, the nese name for plague, 'shu-yi', meaning 'ratt', has been traced back to A.D. 610. Plague to the establishment of quarantine in Venice 1127, using for segregation the house of St. zarus, so giving rise to the names lazaretto and ar house. It was plague that brought into being ls of Mortality at the end of the seventeenth tury in Great Britain, and from them has wn the science of vital statistics; and about s time, it being announced that none who kept tobacconists' shops suffered from plague, there went out an edict at Eton College the sequel of which was that one of the boys "was never whipped so much in his life as he was one morning for not smoaking". In 1828 came a report from two Frenchmen who held history to show that plague first appeared in Egypt in A.D. 543, about the time when under Christian influence embalming gave place to burial; their conclusion was that the air became heavily tainted with decomposition products and started plague, and they add, "Is there a more conclusive or more notable piece of evidence in any science in which facts are not ascertainable with mathematical certainty?"

The properly controlled scientific certainty, when it came, was very different. Yersin, in 1894, discovered the bacillus in rats and men, and Scott lists fifty-four rodents, other than rats and mice, discovered between 1895 and 1935 to suffer from spontaneous plague. The means of conveyance from rat to man became clear in 1897 when Ogata noted that the plague rat's dead body could safely be handled when cold, that it then had no fleas, and that the emulsion made from a crushed flea, taken off a plague rat, gave plague when injected into a mouse. It was nearly ten years later that the English Plague Commission in Bombay showed that the bacilli, multiplying in the flea's stomach, so fill it and regurgitate into the proventriculus that they readily enter the next mammalian host on which the flea feeds. It is a pertinent comment on the wide interrelationship of biology and human infections that it was some forty years later that Iyengar and O'Connor showed independently that *Microfilaria bancrofti* swallowed by Culex may experience just such regurgitation into the anterior part of the mid-gut before it penetrates the mosquito's tissues.

But to return to plague; there is the pneumonic form with its notable epidemic in Manchuria in 1910; and the occult form in ground squirrels in California, the presence of which is now traced by inoculating into experimental animals the fluid from the bodies of the squirrel's fleas. Knowledge of plague has been used to save human life, as by the rat-proofing of houses and ships, and to destroy it, as in the Pakar murder case in Bombay; and as to the latter use, there is the observation that the bacilli can survive in tear or asphyxiating gas and perhaps could be used to spread infection in warfare.

The mode of dealing with this single disease illustrates the book's aim and scope: there are first empirical observation and uncontrolled conjecture; they give place to controlled observation and reasoning; and finally there is established knowledge used by man for good or ill.

There are chapters on the making of the Suez and Panama Canals, the latter finished only when tropical disease had been successfully controlled. There is one on the slave trade with its half-mill deaths yearly, and to the slaves a water allowa on the voyage of half-a-teacupful every third da and there is the introduction by its means i America, it seems certain, of leprosy, filaria dracontiasis, hookworm infection, yaws, and yell fever.

The last eighty pages of the work are filled fifteen short biographies of men, no longer livi selected because their work on tropical medic has not been limited to one problem, and so h escaped sufficient notice in earlier pages. Bibl graphy and indexes are generous. Resear learning and humour, amply backed by t publishers' enterprise, deserve success.

Clayton Lane

A CRITICAL AND HISTORICAL SURVEY OF THE CALCULUS

The Concepts of the Calculus

A Critical and Historical Discussion of the Derivative and the Integral. By Carl B. Boyer. Pp. vii + 346. (New York: Columbia University Press; London: Oxford University Press, 1939.) 18*s*. 6*d*. net.

In the historical survey of mathematics, as of any branch of science, it is customary to ascribe a great discovery to one or more individuals. Without, however, seeming in any way to detract from the full credit due to such brilliant researchers, it must not be overlooked that behind every great step forward there is, invariably, an evolutionary development of ideas which renders that step possible. There are periods of suggestion and anticipation which lead to a stage where the nebulous begins to take form and ultimately becomes precise. But the process does not stop here. A new discovery is somewhat analogous to a roughly-hewn article specially designed for some particular purpose; it will not function to its fullest extent until subjected to a refining development in which greater definition is brought forth, with a consequent extension of the field of validity and useful application. Thus, in time, by a mental process of evolution, any discovery, great as it may be, tends to become less prominent as a separate entity. In the words of J. W. N. Sullivan: "A history of mathematics is largely a history of discoveries which no longer exist as separate items, but which are merged into some more modern generalisation".

An illuminating example of this truth is furnished by the infinitesimal calculus. The mention of this very important branch of mathematics recalls fluxions of Newton and the differential calculu Leibniz. Yet, according to Chasles, the great mathematician of antiquity, Archimedes of Sy cuse, "gave birth to the calculus of the infi conceived and brought to perfection successiv by Kepler, Cavaliere, Fermat, Leibniz and N ton". Thus were the concepts of the derivat and the integral made possible. Yet the calcu as left by Newton and Leibniz was far from sa factory. There were, for example, no valid crite for testing the convergence of an infinite ser though both these great men realized the necess for convergence. Also, the ideas of continuity a discontinuity were far from being clearly und stood or appreciated. Hence, the eighteenth c tury was characterized by considerable dou concerning the validity of the foundations of calculus.

"Had Newton been more precise in the sta ment of his limit method, and had Leibniz be more explicit in professing that he was develop an instrument of invention and not a logi foundation, the period of indecision might not ha ensued. As it was, it required the work of Cauch Weierstrass and others to impart to the conce of the continuous variable, the limit, the derivat and the integral a precision of formulation wh made them generally acceptable."

Thus does Carl Boyer sum up the deficienc of the calculus of Newton and Leibniz in fascinating book, which is the basis of this b discussion. It seems almost that the eighteen century of indecision which brought forth Berkeley-Jurin controversy, the limit concept

Robins, the "Fluxions" of Maclaurin, the alculus" of the Bernoullis and the various conibutions of Euler, Lagrange and others, was cessary to prepare the way for the period of gorous formulation which followed. But the ll story is told vividly and fearlessly by Carl yer, who traces the development of the basic ncepts upon which the modern calculus is unded, from the earliest times to the present y. The eight chapters are filled with interesting cts welded into a continuous narrative which vets the reader's attention almost like a romantic vel. According to the preface, the author's theme—well described by the sub-title—has not before been satisfactorily dealt with. The book is "not a history of the calculus in all its aspects, but a suggestive outline of the development of the basic concepts"; and a very stimulating outline, too! The author almost makes the infinitesimal, Osgood's "abominable little zeroes", or "the ghosts of departed quantities", the indeterminate ratio 0/0, etc., seem like living characters in a work of fiction.

A comprehensive bibliography is provided at the end and the complete volume is both an important and valuable addition to the literature of mathematics. F. G. W. B.

CHEMICAL ANALYSIS

andard Methods of Chemical Analysis

Manual of Analytical Methods and General
ference for the Analytical Chemist and for the
lvanced Student. By Dr. Wilfred W. Scott.
fth edition, edited by Prof. N. Howell Furman
collaboration with Eminent Specialists. Vol. 1:
e Elements. Pp. xxxi + 1234 + 97. Vol. 2:
ecial Subjects. Pp. xxi + 1301–2618 + 97. (Lon-
n: The Technical Press, Ltd., 1939.) 2 vols..
s. 6d. net.

HE rapid growth of analytical chemistry in modern times necessitates that any textok which hopes effectively to cover the fields both pure and applied analysis shall assume nost encyclopædic proportions. The considerle increase in the size of this fifth edition of ott's well-known manual is at least outward idence that it has attempted to deal adequately th these recent advances, a conclusion which is ıply confirmed by a study of the contents. The o volumes of the present edition now cover me 2,700 pages—an increase of nearly 1,000 ges over the fourth edition.

In the first volume, which deals with schemes the analysis of the more important chemical ments, practically all the chapters have been panded and, in many cases, re-written. In dition, there have been included, for the first ne, methods of analysis for gallium, germanium, drogen, oxygen and rhenium. Of these, the st two are not quite as complete as they might , there being missed from the chapter on gallium o's camphoric acid method, which is quite iable, while no colorimetric procedures are given germanium. Also, in the determination of ygen in organic compounds, it is unfortunate at the method given, although neat, is applicable materials containing carbon, hydrogen and ygen only. Apart from these points, the new chapters cover the ground adequately. The second and third parts of volume 1 are substantially the same as in the previous editions, although it is to be regretted that the tables of gravimetric factors have been omitted.

The second volume has undergone even greater changes and is now divided into two parts. Part 1 deals with sampling and applied analysis, and here all the chapters have been brought up to date, while many of them have received considerable expansion, particularly those on alloys, petroleum products, rubber and soap. The section on paper and paper-making originally found under "Miscellaneous Analyses" has been enlarged and raised to the dignity of a separate chapter.

Part 2 deals with special techniques applicable in diverse cases, and here are to be found the chapters on acidimetry and alkalimetry, gas analysis, metallography and solubility. New material which has been introduced consists of sections on the determination of pH by colorimetric and electrometric methods, potentiometric methods, conductometric methods, chemical microscopy, quantitative microanalysis and spectrographic analysis. All these provide excellent surveys of the various procedures, while in some of the chapters are to be found numerous references regarding the application of the methods to special problems.

The manual is commendably free from errors, although one or two have crept in as a result of rearrangement of the text; also Figs. 25, 243 and 267 do not correspond with the legends beneath them. There has been a typographical change which makes for easier reading, while another welcome change has been the provision of an author index. Altogether, revision has considerably enhanced the value of a work that had long established itself as a necessity to analytical chemists.

SCOPE AND LIMITATIONS OF PHYSICAL ANTHROPOLOGY*

By Prof. W. E. Le Gros Clark, F.R.S.,
University College, London

FOR many years now it has been established beyond doubt that man is one of the terminal products of organic evolution, and that he achieved his humanity at a comparatively recent date in geological time. He was an animal dominated by the primitive instincts of the wild creature before he was a man capable of controlling his own destiny by his intellect. He must be studied as an animal before he can be properly appreciated and appraised as a human being. The subject which is concerned with the study of man from this point of view is physical anthropology, and it may perhaps be claimed that, of all the subdivisions of anthropological science, physical anthropology is the most fundamental, since it concerns itself with the physical nature of man, and the physical nature of man underlies ultimately all those intellectual, æsthetic, and social activities which supply the material for other branches of anthropological study.

Zoological Position of Man

The results of the extensive researches carried out in recent years have served to substantiate in general the views held by most anthropologists, namely, that man has relatively close systematic affinities with the anthropoid apes; in other words, that the human phylum was derived (in the evolutionary sense) from a common ancestral group which also gave rise to the modern anthropoid apes. In a number of details, however, a thorough inquiry into morphological comparisons has led to certain modifications of this generally accepted thesis. The reason for this is that comparative anatomists and palæontologists have come to realize that *parallelism* has played by no means an insignificant part in organic evolution. Now this conception considerably complicates phylogenetic problems, for it makes it necessary to distinguish between morphological similarities betokening real genetic relationship and those which are secondarily acquired as the result of convergence, that is, of evolutionary differentiation which may have occurred in the same direction in different groups independently.

It is interesting to note that, in recent yea detailed and careful comparative anatomic studies have led more and more students to t inevitable conclusion that the evolutionary histo of man and the anthropoid apes has been co plicated by the effects of parallelism. The remains no justification, however, for taking t extreme view that these higher primates are in way related to each other. Such a conclusion do violence not only to all the evidence of co parative anatomy, but also to the availal palæontological evidence. The very fact th parallelism has occurred between man and t apes indicates that they are *ultimately* deriv from a common ancestral stock which endow them with similar evolutionary potentialiti Moreover, even if it be accepted that the rep sentatives of this ancestral stock could scarce have manifested the aberrant specializatio characteristic of the modern anthropoid apes, remains reasonably certain that they must ha shown in the structure of their brain, skull a dentition, anatomical characters which wou demand their inclusion in the zoological catego of Anthropomorpha. In other words, it remai true to say that man had a simian ancestry. Th relationship is well emphasized in a new classi cation of mammals recently put forward by G. Simpson, for he includes man and the anthropo apes in one superfamily, Hominoidea.

Palæontological Evidence of Human Origi

Between the Miocene genera of anthropoid ap and the earliest fossil record of man there remai a large gap in the palæontological sequence. T oldest representatives of the Hominidæ of whi we have any real knowledge are Pithecanthrop from Java, and Sinanthropus from the ea Pleistocene of China. The fact that some anthr pologists have classified the remains of these ea representatives of man as two different genera a good example of the results of the difficult encountered in the study of rare fossils of t type; for, since such fossils usually turn up sing and often at intervals of several years, each c is made the subject of intensive study without t advantage of adequate material for comparis nsequently, the anthropologist tends to exagrate in his own mind the significance of small uctural differences which, after all, may be erely an expression of interspecific or even of dividual variation. This now appears to be rtainly the case with Pithecanthropus and anthropus, for, since the initial discovery of e type specimens, the remains of a number of her individuals have been found which emphasize e wide range of variation in both groups. Indeed, e overlap in variation between the two is quite nsiderable, and it is clearly desirable that they ould both be included, for purposes of classifition, in the one genus, Pithecanthropus.

---

* Based on the presidential address to Section H (Anthropology) of the British Association delivered at Dundee on September 1.

The range of variation among members of this oup may be illustrated by reference to the cranial pacity of adults, which varies from 750 c.c. to 200 c.c. Now such a range of variation in the all number of individuals which has been und is very remarkable, for in so ancient a type man it can scarcely be attributed to the effects extensive intermixture. The knowledge that is variability does occur should therefore guard thropologists against making too hasty assumpons on the basis of the study of isolated specimens.

The variability manifested by these early reprentatives of the Hominidæ serves to emphasize e fact that the range of genetic variation in man quite exceptional in contrast with lower animals. other words, man is distinguished physically om other mammals not only by the possession of rtain general anatomical characters, but also by e degree of variability which they show. The tent to which these genetic characters can be odified by environmental influences is also a istinctive feature of man. This variability ndoubtedly has far-reaching implications in the udy of all branches of anthropological science. seems certain, for example, that it has been important factor in the evolution of human ciety, for it allowed a wide range in the developent of individual abilities, and also provided for e considerable plasticity which is a pre-requisite r the building up of complex types of social rganization.

Future of Physical Anthropology

Apart from palæontology, it may be doubted hether physical anthropology is likely to advance ur knowledge of racial origins and differentiaion very much beyond its present state with he techniques now available. The reasons for his somewhat pessimistic prognosis include the ifficulty of acquiring adequate skeletal material rom which the racial composition of populations the past can be inferred; the frequent imossibility of identifying racial types by the examination of skeletal material only; the fallacy which may be involved in the assumption that certain craniometrical similarities necessarily indicate a true genetic affinity; and the difficulty of eliminating the effects of environmental influences in modifying physical characters which otherwise have a genetic basis.

A valuable aspect of the study of present and past populations from the historical point of view by the rigid application of biometric technique is that it permits the testing of the popular conceptions so commonly held to-day regarding the equivalence of race and nationality. No one will doubt the need for the clarification of such ideas. The physical anthropologist, indeed, has an important duty to fulfil in the discussion of modern social problems, by providing objective evidence to show whether there is any truth at all in the tenet that 'nation' and 'race' in Europe are in any instance comparable terms. Such studies as have been made on this question have hitherto led in general to negative results.

In so far as history can be said to provide a basis for prognostication, physical anthropology as a historical science has a considerable practical significance. The study of the bodily changes which man has undergone in the past gives a clue to the nature and extent of the changes which may be anticipated in the future. *But what is far more important for the same purpose is the study of man as he is to-day.* Sociological problems are becoming more and more forced on our attention and demand for their solution a conscious control of processes which have hitherto been left to chance. The improvement of health and physique and their relation to nutritional and climatic factors, the effects on physical type of the redistribution of the populations of the world, the results of the hybridization of different racial types, the relation of changes in the reproductive rate to human variability and the composition of regional populations, all these are practical problems which can be approached systematically and scientifically only if we have adequate data regarding the physical nature of man in the conditions under which he now lives.

We still lack this essential knowledge. In Great Britain, for example, there are no proper records which show the variability of different sections of the population living under different nutritional conditions and in different environments. Still less is there any real knowledge of the potentialities for growth and development of native populations living under optimal conditions of nutrition and hygiene. Yet a study of the normal variability of man to-day, and of his bodily reactions to environmental influences, must clearly be a necessary basis for any assessment of changes which are to be anticipated in the future. Let us note briefly the lines along which physical anthropologists may most profitably seek for this information.

Human genetics. The study of human genetics offers practical problems of considerable urgency, for no one doubts that the mode of transmission of hereditary defects, which may be manifested in structural abnormalities, metabolic disorders, or susceptibility to diseases of one kind or another, should be elucidated in all possible detail. The problems of human heredity form the basis of the whole science and practice of eugenics, and the eugenist requires to have all the data of human heredity at his disposal if he is to exert any conscious control over the destiny of mankind in the future.

Apart from the practical significance of human genetics in relation to the health and progress of mankind, this study has also a direct relation to the more academic problems of the anthropologist. Physical anthropologists have on several occasions been criticized for employing as criteria in their studies of racial affinities physical characters the genetic basis of which is unknown. No doubt such criticism is often justified, for it is clear that only those characters which are the expression of genic differences have any validity in taxonomic problems. There is evidence that the shape of the head is certainly in part determined by heredity, but there is also evidence that it can be modified by post-natal influences. Similarly, it is well recognized that the height of an individual is closely correlated with nutrition, but it is known that it also depends partly on heredity. The relative importance of genetic and environmental factors must ultimately be determined for all such characters as these.

The question of the possible linkage of phenotypic characters is another problem of human genetics which demands intensive investigation, since this phenomenon may permit the recognition of latent defects in cases where they are linked with a physical trait detectable by superficial observation or appropriate measurement. The possible relation of physique to susceptibility to disease is particularly important. It is commonly supposed that a relation of this kind does in fact exist. Physical types, such as those termed 'asthenic', 'pyknic', and 'athletic', have been defined, each with their particular advantages and weaknesses; but, so far, the evidence in favour of such a sharp classification is equivocal, and the same doubt still applies to the supposition that certain racial types are particularly susceptible to infections of one kind or another. For example, there is a current belief that the Negro, as the result of an inherited predisposition, is specially liable to tuberculosis, and that certain types racial miscegenation likewise lower the resistan to such diseases. Yet in a recent and caref survey by Williams and Applewhite, the conclusi is reached that there is little if any differen between the White and the Negro in resistance tuberculosis (given equal opportunities for medic treatment), nor do miscegenetic types of the Neg really show a greater incidence of tuberculosis.

The possibility of a genetic linkage of characte also raises the question how far inherited physic traits may be related to an inherited mental di position. It is common enough, in text-books anthropology, to find different varieties of tem perament assigned to different racial types. F example, it is stated in a recent comprehensi work on human heredity (by Dr. Lenz, profess of racial hygiene in the University of Munic that the Mediterranean race (of which, in Europ the southern Italians are perhaps the best repr sentatives) is volatile and frivolous in temper ment, has less sense of truth and honour than th Nordic, and, in respect of rational endowme and character, occupies an intermediate positio between the Nordic and the Negro. The Nord race, on the other hand, is supposed to be endowe with creative energy, with a vigorous imaginatio high intelligence, and an unusual degree of sel control.

Physique and nutrition. The problems of huma genetics and the supposed association of ment traits with demonstrable physical characters a complicated by the growing recognition duri recent years that nutrition plays a highly importa part in determining the physical variations seen i different races and in different individuals. It unnecessary to state that a broad relation betwe nutrition and physique has always been accepte by anthropologists. Stature, weight, ches dimensions, and so forth, can all be correlated wit nutrition. But the suggestion is now put forwar by competent dietitians that the effects of mal nutrition may be much more extensive, not onl as causal agents underlying many types of varia tion in physical characters, but also in determinin susceptibility to different types of infection. I this is true (as it undoubtedly appears to be) i clearly demands the serious attention of physic anthropologists.

In Great Britain, indeed, evidence has been pu forward which suggests that malnutrition may b far more extensive in the lower economic levels o society than has hitherto been suspected. Clinica and anthropometric comparisons of the childre of relatively wealthy parents with those of poo parents have demonstrated a marked contrast i physique, general health, and susceptibility t infections. There is evidence, for example, tha e infantile mortality from respiratory infections considerably higher in the poor districts of large wns than in the residential areas of the richer ctions of the population, and there is also idence that the predisposition to respiratory fections is related to under-nourishment. Morever, direct experiments (although of a limited ture) have been carried out on human material which the effects of different diets on growing ildren have been recorded.

It will not be doubted that, if there is indeed idespread malnutrition, it is a matter of national terest that it should be corrected as soon as ossible. But an essential preliminary to any largeale plan of action is to collect precise information garding the extent, distribution, and degree of nder-nourishment. Here is a problem in the lution of which the physical anthropologist ould play a predominant part. He has at least e experience and technique which will enable m to seek an answer to one of the most urgent eliminary questions: By what somatometric ethod, which is both reliable and convenient of plication, is it possible to assess nutritional atus ?

It is perhaps a matter for surprise that in Great ritain we still have no adequate standard of hat may properly be called *normal* physique, as basis for comparison when seeking for evidence f malnutrition. This is partly due to the fact at available anthropometric data apply to ixed populations from different parts of the untry, in which no attempt has been made by reful clinical examination to eliminate those dividuals who may be under-nourished, or otherise unfit physically. It is also a fact that the hysical standard is by no means fixed and nchanging. There is evidence, for example, that e average height of the population, not only in reat Britain but also elsewhere, is rising rather pidly, and it has been recently estimated that this crease may be as much as one centimetre in very 12½ years. It is possible that this increase directly referable to improved nutrition, though here are some reasons for supposing that this xplanation may not be completely adequate. It mains conceivable that it may possibly represent definite orthogenetic trend in human evolution hich is manifesting itself in statistical analysis.

In order to obtain a basic standard of physique r series of standards) for comparative studies, it in the first place necessary to carry out a comlete survey of the country by the systematic xamination of samples of the population from ifferent districts. Such a survey would require he close collaboration of physical anthropologists ith clinicians, medical officers of health, dietitians, nd social workers, in order to attempt a correlation between physical development and the normal healthy condition of body and mind, and, if possible, to relate this also to the social conditions of life. In fact, an attempt should be made to extend the health surveys which have been recently carried out in Great Britain and a number of other countries, the aim of which has been to correlate also the clinical assessment of nutritional status with anthropometric observations.

Observations on the relation of nutrition to physique, capacity for work, and susceptibility to disease are also waiting to be carried out among native peoples in many parts of the world. Some excellent work along these lines has been started in India, Africa, and also in China, where information has been collected regarding the composition of the diet of different sections of the native population. Here the field anthropologist must necessarily give his aid, since he is in the best position to obtain a detailed record of the food elements of the diet which are ordinarily obtainable at different seasons, to study the local customs in the preparation of the food for consumption, and also to collect samples of the various foodstuffs for analytical study by the biochemist. It has already become evident from such observations that in some cases the native diet is hopelessly deficient in certain essential food elements which are necessary for the development of a normal physique and for the maintenance of health. The elucidation of such defects in the diet must surely in the future be a powerful factor for success in colonial administration.

To carry out nutritional surveys in native populations, the physical anthropologist will also require to examine the somatometric indexes which have been worked out by reference to European peoples, for they will probably need modification to adapt them to different types.

The fields of research to which we have directed attention serve once more to emphasize the fact that the physical anthropologist of the future must be essentially a field-worker if he is going to develop his subject along progressive lines. He must also be a man of sound biological training if he is to acquire a real insight into the problems which are set for him. Some of these problems have a very intimate relation to human happiness and human suffering, and their investigation is a matter of urgency.

The science of physical anthropology has contributed much to the study of the past history of the human species. By the study of modern populations it has a still more important function to fulfil : the accumulation of data on the basis of which it will be possible in some measure to control the destiny of mankind in the future.

SOLAR AND TERRESTRIAL RELATIONSHIPS

A DISCUSSION on solar and terrestrial relationships had been arranged to take place on September 5 as part of the programme of Section A (Mathematical and Physical Sciences) of the British Association meeting at Dundee. The meeting was not held, owing to the international situation, and the following account contains the subject-matter of contributions from Dr. E. V. Appleton (radio effects), Mr. H. W. Newton (solar phenomena and terrestrial magnetism), Dr. A. D. Thackeray (solar phenomena), Prof. L. Vegard (auroral phenomena and the physics of the upper atmosphere), Prof. W. M. H. Greaves (the 27-day recurrence tendency of magnetic storms) and Prof. F. J. M. Stratton (general summary).

Many attempts have been made in the past to correlate solar and terrestrial phenomena. Until quite recently, the only one that was found to show a clearly measurable relationship was that between sunspot activity, auroras and magnetic activity. There is no direct meteorological effect of any serious importance, although in some climates tree-rings suggest a connexion of a complex type with the sunspot cycle not shown up by ordinary data. The recent study of the ionosphere has shown a new relation, involving an increase in ionization in the upper atmosphere accompanying increased magnetic activity at times of maximum sunspot activity; this relation appears in a peculiarly clear-cut fashion at times of chromospheric eruptions which closely coincide with short-wave radio fade-outs. The correlations so far found can all be attributed either to a stream of corpuscles ejected radially from the sun's surface or to an increase in ultra-violet solar radiation.

Nearly every type of solar activity is capable of emitting a stream of particles or high-frequency radiation which may ultimately strike the earth's upper atmosphere. In the lowest levels of the sun's atmosphere, direct observation reveals sunspots, faculæ and granulation; with the spectroscope, high-level flocculi and prominences are detected (chiefly in hydrogen or ionized calcium light); still higher, coronal streamers suggest a permanent outward flow of particles. Eruptive prominences, which may ultimately attain velocities of the order of 600 km./sec., form a spectacular example of the sudden expulsion of matter from the sun, presumably through radiation pressure; the motions of prominences, however, as revealed by cinematography, show many characteristics which are difficult to explain even in terms of a complex interaction of radiati pressure, gravitation and electrical forces.

Radiation pressure is insufficient to support t whole mass of chromospheric gases, but the dyna ical concept of turbulence has partially solv this difficulty. A turbulent velocity of 15 km./s in the chromosphere is indicated; in the low layers it is on a much smaller scale. The sho lived granules, with a life-time of only thr minutes, represent permanent activity all over t sun's surface, *independent of the* 11-*year sunsp cycle*, while chromospheric eruptions represe temporary localized activity on a large scale. The eruptions consist of intense brightenings in hydr gen and calcium light which sometimes last only few minutes. Thanks to the spectrohelioscop perfected in 1924 by Hale, a practically continuo watch for these short-lived phenomena is now ke throughout all longitudes by international operation. It has been found that 50 per cent the brightest eruptions are associated with *simu taneous* radio fade-outs; with the fainter eruptio the association is much less direct.

The statistical relationship between sunspo and magnetic storms may be summarized follows: (*a*) there is a general similarity in th frequency curves of the two phenomena in th 11-year cycle; (*b*) the largest sunspots, at the tim of their passage across the central solar meridia are often associated with large magnetic storms (*c*) the most favoured position of the associate sunspot at the time of the magnetic storm is abo one day past the central meridian. The time-la suggests the time of travel of a stream of particl from sun to earth. The relationship becom progressively more obscure when smaller spots a studied.

It is natural to inquire whether this relationshi is due to the presence of chromospheric eruption which are most commonly observed in or ne large active sunspots. A distinct relationship ha been established between eruptions and magneti storms, similar to that with sunspots. Of th twenty-nine greatest eruptions observed since 189 twenty-one were found to be followed withi 4·0 days by a magnetic storm, and half of thes storms were classified as 'great'. Magnetic storm do in fact appear to be more closely associated wit chromospheric eruptions than with sunspots.

The association of chromospheric eruptions wit ionospheric disturbances is of a different character (*a*) there is no time-lag; (*b*) the eruption can b effective wherever it occurs on the solar disk

·) the ionospheric disturbance is practically)nfined to the earth's sunlit hemisphere ; (d) there an accompanying small perturbation of the ırth's magnetic field. These four facts are constent with the suggestion that the solar agency ultra-violet radiation emitted from active egions of the solar surface. The agency responble for magnetic storms, however, is to be looked r in a radially ejected stream of high-velocity articles. The observations favour a common rigin of radiation and particles in an active ortion of the sun's surface, which may also but ot necessarily be marked by a large sunspot. The ssociation of terrestrial phenomena with sunspots ust be regarded as an indirect one ; it is only ecause they are so easily observed that sunspots ave been taken as a convenient index of solar tivity.

A further relationship between sunspots and rrestrial magnetism is shown by the fact, known r many years, that magnetic storms tend to recur t intervals of one synodic solar rotation (about 7 days). A catalogue of 403 storms based on reenwich records for the years 1874–1927 has een used to study this relationship in detail. hese were divided into five groups according to tensity, represented by the mean of the three mponents *D*, *H* and *V*. The history of stormays following each storm was followed up and the ndency to recur after 27 days was found to be nfined to the less intense storms (less than 30 γ) : in the weakest storms (less than 150 γ), ıere is a definite additional tendency to recur at tervals of 54 days.

This result can be expressed in another way : if ttention is confined to storms which tend to recur fter 27 days, it is found that the ratio 'sequence torms' to all storms decreases progressively from ·25 to 0·05 as one passes from weak to great orms. This result does not contradict the conclusion that magnetic storms are due to radial reams of corpuscles from active regions of the un ; it merely suggests that the most intense solar isturbances which eject such streams are comaratively short-lived and will not survive a solar otation. The 27-day recurrence has been found persist throughout spotless periods of minimum ctivity ; thus, as implied previously, the spots hemselves must not be regarded as the origin of he corpuscular streams.

The frequency of auroras has long been known o follow the cycle of solar activity ; there is also slight tendency for intense auroras to occur near he times of the equinoxes, when the earth lies in he plane of the equatorial belt of the sun where ctivity is greatest. The spectrum of auroras onsists of bands (chiefly due to nitrogen) and lines lue to atomic oxygen and nitrogen, neutral and ionized). The wave-lengths of the strong green and red lines have been measured with great accuracy, and, with the help of knowledge of atomic energy levels, attributed to 'forbidden' transitions of neutral oxygen.

The presence of ionized oxygen and nitrogen indicates the action of particles of high energy. The work of Störmer has shown how the streamers may be identified with the paths of electrified particles entering the earth's magnetic field. Analysis of the intensity distribution within auroral bands yields a mean temperature determination of – 44° C. There is no evidence of any increase in temperature with height either from band analysis or from measures of interferometer fringes of atomic lines. Further, the observed light intensity along auroral streamers suggests that the density of atmospheric gases diminishes but slowly within the auroral region from 100 km. to 800 km. It is suggested that matter is driven to these heights by electric forces in an ionized or partially electrified atmosphere.

A theory proposed by Vegard in 1923 accounts for the main facts on the assumption of a stream of photon radiation, the wave-length of which corresponds to soft X-rays, in addition to the ordinary temperature radiation and corpuscular rays emitted by the sun. The incidence of this radiation on the extreme upper atmosphere produces a sort of terrestrial corona. The theory has been very successful in explaining the chief layers of ionization in the upper atmosphere. The soft X-rays will produce two ionization maxima ; the first, formed at a high altitude by high-speed photo-electrons, is identified with the F_2 layer, which surrounds the whole earth, but is higher by night than by day ; the second, at a low altitude where the absorption per unit length is a maximum, is identified with the *E* layer, which is confined to the sunlit hemisphere. The energy of the photons must be about 1000 volts to account for the observed heights of the *E* and F_2 layers. Finally, the absorption coefficient for rays in a large range of wave-length (100–1000 A.) is a maximum, so that these rays will produce an ionization maximum at about the same height—calculated to be 200 km.—which will be confined to the sunlit hemisphere. This maximum is identified by Vegard with the F_1 layer.

The variations in ionization in these three layers may be very efficiently studied by means of the radio sounding method, developed by Appleton and others. The ionosphere may, in fact, be regarded as a solar laboratory in which the effects of high-frequency radiation and particles emitted by the sun may be analysed. By timing echoes of vertically transmitted waves, a relation is obtained between equivalent height of reflection and radio-wave frequency. At a critical frequency, echoes from the ionosphere are lost, and this gives a clue to the maximum electron density in any layer. Layers E and F_1 show comparatively smooth diurnal, seasonal and sunspot-cycle variations, all of which confirm the supposition that these layers are produced by high-frequency solar radiation. The long-scale variations in ionospheric reflectivity do, in fact, give a very perfect reproduction of the 11-year cycle of solar activity. The ionization in layer F_2, however, suffers remarkable irregularities, particularly during magnetic storms, when the ionization maximum is less than normal. The most striking type of ionospheric irregularity is that known as an irruption or fade-out, which is usually associated with a chromospheric eruption. Here the absorption is so great that the echo may be entirely lost, but the height of reflection is not usually greatly affected.

The question of the ultimate character of the short-wave solar radiation associated with these disturbances (for example, its frequency and whether it consists of continuous or line-emission) is still quite unsettled. The spectrum of chromospheric eruptions in the observable range has been found to consist of lines due to H, He and Ca^+. Photometric measures show that during an eru tion, the total Hα radiation from the sun increas by only a few tenths of one per cent; it is qui clear that what the spectrohelioscope observer se is a secondary effect, and that the primary distu bance consists in the leakage of unobservab ultra-violet radiation. As Milne has pointed ou given an increase of radiation, the ejection of stream of high-speed particles is easily accounte for by radiation pressure. Lyman emission hydrogen is insufficient to account for all th observed effects, and it is probable that we hav to deal with a mixture of line and continuou radiation. Continuous emission is not normall observed in the visible region, although a sma increase at wave-length 3220 A. has been detecte in one exceptional eruption.

Further analysis of ionospheric disturbances b radio sounding probably holds out greater hop for the ultimate solution of the problem than th observation of secondary solar effects in the visibl spectrum. Finally, the spectra of 'sunlit aurora recently observed by Störmer promises a fruitf field for research into the uppermost region where the solar rays first strike the earth atmosphere.

OBITUARIES

Sir William Pope, K.B.E., F.R.S.

WILLIAM JACKSON POPE, the great chemist, was the eldest son of William and Alice Pope who at the time of his birth (March 31, 1870) lived in New North Road in the City of London. On leaving the Cowper Street Endowed School, Pope proceeded to the Finsbury Technical College, where he was one of H. E. Armstrong's earliest pupils. He followed Armstrong to the Central Institution (now the City and Guilds' College of the Imperial College of Science and Technology), where the scheme of scientific studies having no reference to outside examining bodies did not lead to a university degree but gave Pope a rigorous training in chemistry, classical crystallography (under H. A. Miers) and in research methods admirably suited to his genius. From that time dated the unique friendship between Armstrong and Pope which was only broken by the former's death in 1937.

While still a student, Pope began his own crystallographic investigations of organic compounds. He also collaborated with F. S. Kipping, then Armstrong's assistant, in important investigations in the chemistry of camphor and on the constitution and characterization of externally compensated compounds.

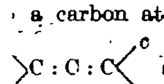
Pope's first appointment (1897) was that of head of the Chemistry Department of the Goldsmiths' Institute at New Cross, and at the same time he was lecturer on crystallography at the "Central". I 1901 he became professor of chemistry and head the Chemistry Department at the newly built Scho of Technology, Manchester, becoming professor chemistry in the University of Manchester in 190 when the School was made the centre of the Facult of Technology, and on that occasion Pope receive his first university degree; he had been elected t the fellowship of the Royal Society in 1902. Pop was elected to the professorship of chemistry in th University of Cambridge in 1908 in succession t J. D. Liveing, who had held the chair for fort seven years, and in the following year he was electe to a professorial fellowship at Sidney Sussex Colleg

Pope's enduring fame will rest chiefly on his wor on molecular dissymmetry. Pasteur had laid th foundations of stereochemistry in 1849, and up t the time of Pope's work at the Goldsmiths' Institut all the optically active compounds studied b Pasteur and his successors contained in the molecul at least one carbon atom having an asymmetri environment. The presence of this 'asymmetri carbon atom'—a carbon atom united to four differen atoms or groups tetrahedrally arranged round it— in the molecule was up to then regarded as bein essential for the particular compound to be capabl of exhibiting optical activity. As Pope has frequentl pointed out, it is probable that the use of thi rticular phrase with its narrow implication tended r many years to delay progress in stereochemistry, ce it became usual to correlate the exhibition of tical activity with the asymmetry of a particular om present rather than with the dissymmetry of e molecule as a whole. By the optical resolution externally compensated compounds in which the oms nitrogen, sulphur, tin and selenium had ymmetric environments, Pope was the first to ow that the presence in the molecule of a carbon om having an asymmetric environment was not sential for the exhibition of optical activity. In s classical work he had as collaborators S. J. achey, A. W. Harvey, E. M. Rich and H. A. D. ville, and its success and that of numerous chemical d stereochemical investigations carried out simulneously depended on Pope's knowledge and use of ystallography and also on his introduction of the e of the camphorsulphonic acids, first adequately scribed by Kipping and himself, for the resolution externally compensated bases.

During the Manchester period, Pope had as sistants C. S. Gibson and John Read. With achey he prepared the first organic compounds of tinum and with Gibson those of gold, and this rk, so novel and simple in its conception, was pical of Pope's knowledge and genius in attacking ndamental problems. Another striking example of is was the elegant work carried out with Read ich resulted in the resolution of externally comnsated chloroiodomethanesulphonic acid, CHClI. $)_3$H. This work showed that it is only necessary r the attachment of four different atoms or groups, ne of which need contain a carbon atom, to a gle carbon atom to condition stable optical activity. is compound is still the simplest substance showing rmanent optical activity. At this time also, Pope d Read began the work which resulted in the troduction of optically active oxymethylenecamphor alternative to the use of the camphorsulphonic ids for the resolution of externally compensated imary and secondary amines.

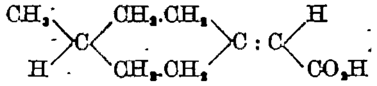
Since his student days, Pope had been profoundly terested in the relation between chemical constituon and crystalline form. For many years he and . Barlow worked on this subject, and beginning in 06 they published a series of long and detailed pers in which the valency volume theory was veloped. After some time it became evident that e fundamental conceptions on which the theory as based were too circumscribed, but the work ey carried out has considerable value in the history the subject which has been so ably developed by r William and W. L. Bragg and other workers.

Following Pasteur, van't Hoff had realized that ganic substances can be formulated which have antiomorphous configurations and yet contain no rbon atom having an asymmetric environment. e showed that on account of the tetrahedral rangement of the atoms or groups attached a carbon atom, allene derivatives of the type



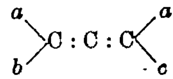
$>C:C:C<\begin{matrix}c\\d\end{matrix}$

should exist in enantiomorphously related forms and therefore be capable of exhibiting optical activity. Pope realized that the compound 1-methyl*cyclo*hexylidene-4-acetic acid,



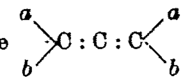
$$\begin{matrix}CH_3\\H\end{matrix}\!>C<\!\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}\!>C:C<\!\begin{matrix}H\\CO_2H\end{matrix}$$

which has an enantiomorphous configuration and contains no carbon atom having an asymmetric environment, resembles the above type, and he and W. H. Perkin (then colleagues in Manchester) commenced its synthesis in 1903 and completed it in 1906. Later they were joined by O. Wallach, and adequate quantities of the compound became available for the resolution experiments. In the latter, Read played a leading part, and the successful accomplishment of this difficult piece of work constituted a most important development in stereochemistry. Actually, as Pope also showed, van't Hoff might have stated the case more generally because the above compound is of the type



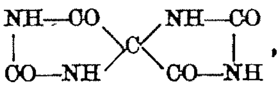
$\begin{matrix}a\\b\end{matrix}\!>C:C:C<\!\begin{matrix}a\\c\end{matrix}$,

and compounds of the type



$\begin{matrix}a\\b\end{matrix}\!>C:C:C<\!\begin{matrix}a\\b\end{matrix}$

are also theoretically capable of exhibiting optical activity. In immediate extension of this work, Pope and his co-workers obtained striking proof that organic compounds can retain their configuration throughout a series of reactions in which the molecular symmetry undergoes profound change. A further example of this is his work with J. B. Whitworth on *spiro*-5 : 5-dihydantoin,



probably the most complete and detailed stereochemical and crystallographic study published in recent years. Pope's work on 1-methyl*cyclo*hexylidene-4-acetic acid has been responsible for almost all the developments in stereochemistry by many workers during the last twenty-five years, owing to the fact that he defined the conditions of mirror-image isomerism, namely, that for mirror-image isomerism the molecular configuration may possess any elements of symmetry excepting a centre of symmetry or a plane of direct symmetry.

Apart from his acknowledged pre-eminence in crystallography and stereochemistry, Pope carried out outstanding work on photographic sensitizers (with W. H. Mills), on the direct synthesis of 'mustard gas' (with C. S. Gibson) and on the extension of Werner's theory of the configuration of complex co-ordination compounds to those containing triamines and tetra-amines (with F. G. Mann).

Pope was president of Section B (Chemistry) of the British Association (1914), president of the Chemical Society (1917–19), president of the Society of Chemical Industry (1920–21), president of the Union internationale de Chimie (1922–25), president of the Federal Council for Chemistry (1918–35), president of the Solvay Chemical Conferences (1922–36) and

Prime Warden of the Goldsmiths' Company (1928–29); he had been chairman of the City and Guilds of London Institute since 1932. He was created Knight Commander of the Order of the British Empire in 1919 and Grand Officier de l'Ordre de Léopold two years ago. He was honorary member of no less than twelve foreign academies and a member of at least ten British scientific societies. He received the Davy Medal (Royal Society), the Longstaff Medal (Chemical Society), Dumas Medal (Société de Chimie industrielle), Lavoisier Medal (Société chimique de France) and Messel Medal (Society of Chemical Industry), besides the honorary doctorate of seven universities.

All who had dealings with Pope, whether as friends, collaborators or pupils, could not fail to be impressed by the true greatness of the man. He was extremely well informed in English and foreign literature and in affairs generally; his judgment and advice were invariably sound. Actually Pope was very shy, but in conversation he was brilliant and witty and few could tell a good story better than he. He was a charming host and loved the company of his friends and life generally. He was a connoisseur and his collections of alchymical pictures, chemists' mortars and drug pots are unique; his library of chemical and general literature has long been the envy of many colleagues. Pope was a most graceful speaker in English as well as in French and German; he could easily translate the spoken word from French directly to German.

For some years Pope had been in poor health, against which he struggled with amazing fortitude, and he continued to carry out his duties and perform extra tasks which must have taxed him greatly. During the last three years he suffered intensely and he bore his sufferings in silence. The end came on October 17 and, after a quietly dignified service taken by his friend, the Master of Sidney Sussex College, his body was cremated in Cambridge.

"Post tenebras lux"

CHARLES S. GIBSON.

Prof. Albert Gilligan

By the death of Albert Gilligan at Storth, near Milnthorpe, on October 14, the science of geology has lost an able exponent. Born on July 26, 1874, he was educated at Wolverhampton Grammar School and at University College, Cardiff. After service as science master at Glossop County School, Gilligan joined the geological staff of the University of Leeds as assistant to Prof. P. F. Kendall. Under the influence of Kendall he became interested in physical geology, particularly that of Yorkshire, and his first published work recorded the denudational effects of a severe storm in that country. This interest remained with him throughout his life.

Gilligan had the ability to lecture in a clear and enthusiastic manner, easily understood by non-geological audiences, and in so doing, perhaps, he rendered his greatest service to the science of geology.
For many years he gave series of lectures througho
Yorkshire, many to the mining community, others
societies of many kinds, and through these ma
many converts to geology. Gilligan also encourage
the work of local geological societies, and his servic
were always at their disposal for a lecture or
description in their journals of a local section.

Later, Gilligan became interested in sedimenta
petrology, a branch of geology then overshadowe
by the igneous side of petrology. He developed
technique of heavy mineral analysis, and turning h
attention to the Millstone Grit, continued the wor
on its sedimentation initiated by Sorby. In 19
he read the results of this pioneer investigation befo
the Geological Society of London, and in 1921
was awarded the Murchison Fund of that Societ
He had in 1920 been made reader in geology in th
University of Leeds and in 1922 he succeeded Kend
in the chair of geology.

His work on the Millstone Grit had led Gilligan
the problems of Middle Carboniferous palæogeograph
and in 1929 he gave, as his presidential address
the Yorkshire Geological Society, an address entitl
"A Contribution to the Geological History of th
North Atlantic Region" in which he summariz
the evidence for a Palæozoic and Pre-Palæozo
'Atlantis'.

From 1922 Gilligan was curator of the Ce
Duncombe Observatory, and he did much to fost
the study of astronomy. He also played his part
the administration of geological societies, serving
the council of the Geological Society. In universit
administration he was closely concerned with studen
activities especially in athletics, and he did much
promote friendly relations between staff and student
He had a sincere understanding of the difficulties
students whose lack of means handicapped the
studies, and many have cause to be gratef
for the ready help which Gilligan so often generousl
gave.

Gilligan was a delightful companion in the fiel
keenly interested in archæology and natural histor
It is the regret of all his friends that he was n
permitted to enjoy, in the foothills of the La
District, his retirement from academic labours.

R. G. S. H.

WE regret to announce the following deaths:

Prof. A. Busi, professor of radiology in t
University of Rome, aged sixty-five years.

Vice-Admiral Sir Percy Douglas, K.C.B., C.M.G
hydrographer of the Navy during 1924–32, o
November 4, aged sixty-three years.

Mr. R. C. Lambert, librarian at the Athenæu
Club during 1922–35, on November 5, aged seventy
one years.

Prof. C. F. Shaw, professor of soil technology i
the University of California, on September 12, age
fifty-eight years.

Dr. J. H. T. Tudsbery, honorary secretary, formerl
secretary, of the Institution of Civil Engineers, o
October 10, aged eighty years.

NATURE

SUPPLEMENT

Vol. 144 SATURDAY, NOVEMBER 11, 1939 No. 3654

THE SEVENTH INTERNATIONAL CONGRESS OF GENETICS

HE Seventh International Congress of Genetics was unique in more than one y. As described by Prof. Crew in NATURE of tember 16, p 496, it was held during a period high political stress, and it accomplished some- ng that perhaps no other international congress l be required to attempt again. The enthusiasm the six hundred men of science present, nbined with a well-thought-out organization, ained the attention and support of all geneticists o were present in Edinburgh during an eventful ek of turmoil. The following pages provide urvey of the proceedings.

The Congress not only achieved success in the rk of the sections, but will also be remembered at least one other direction. The exhibits, ich included charts, diagrams, photographs, gether with dead and living material of plants d animals, occupied the laboratories of the new ological and Engineering Departments of the iversity of Edinburgh. Under at least a hundred d fifty microscopes (probably many more) were les illustrating most of the branches of cytology. ese exhibits enabled one to see for oneself how at was the advance in cytological technique, to perhaps for the first time heterochromatin or omosome splits, and to judge the grounds on ich controversial matters were based. The plant ibit in the laboratory ranged from magnificent nonstrations of the origins of maize, the genetics wheat hybrids, and the cyto-genetics of Datura, the illustration of scientific method in the lysis of the peculiarities of fruit crops and nt pigments. In addition, there were living ibits of genetic characters in a number of plant cies. One laboratory was filled with charts and grams recording the genetics of Drosophila and physiological actions of the genes, while another laboratory contained exhibits on the inheritance of colour in the cocoon of the silkworm, and the diseases to which man is subject. A large exhibit of animal genetics covered the inheritance of characters in rodents, rabbits, and other animals. A notable feature was the organization by Dr. Koller of an exhibit of living plants of Pisum, Lycopersicum, Primula, Antirrhinum, Nicotiana and other genera. These were arranged to illustrate the characters which are controlled by known genes. One of the crops was so well grown that members of the Congress who were specialists on this crop were able to use the plants for observational purposes.

It is obvious that the success of the Congress was due to the excellent organization of Prof. F. A. E. Crew, his committee and staff. Both previous to the Congress and during the Congress in normal times the position of the general secretary is an onerous one. When each day of the Congress brought more news and rumours of war, it was doubtful whether the Congress could continue. By a complete reorganization, only possible by excellent team work, the sections were able to complete their work, the exhibits were received, erected and dispatched in safe custody, and each individual member of the Congress who was directly or indirectly affected by the political upheaval was made to feel that he was being personally looked after by the general secretary and his able staff.

Science will not falter so long as the spirit initially engendered by the staff of the Institute of Animal Genetics at Edinburgh and propagated by the members of the Congress continues among the research workers of the world.

GENE AND CHROMOSOME THEORY*

By Dr. H. J. Muller

THE treatment of gene and chromosome theory was on a far more analytical plane than ever before. Thus, the multiform variations of behaviour of chromosomes at meiosis, and the rules governing these variations, were shown by Darlington to trace back to variations in two primary factors: the region (centric or telic) in which pairing begins, and the time limit set to the pairing process; normally, these must be adapted to each other, so that a mixing of two systems tends to disturb the balance.

Regarding the mechanism whereby structural changes in chromosomes come about, a series of experiments by the present author and co-workers was reported, substantiating and extending, for Drosophila, the earlier conclusions of Stadler, of McClintock and of Sax on plant material, and of Muller and Belgovsky on Drosophila, to the effect that the manifold kinds of structural changes capable of surviving indefinitely are all caused by two distinct primary processes, succeeding one another. These are: (1) breakage of the chromonema at two or more points, followed (2) (though not until after the spermatozoon stage is passed) by two-by-two junction between the adhesive broken ends, giving a new linear order. Distant breakages, giving gross changes, were shown to result from separate individual ionizations, but nearby ones, giving minute rearrangements, to result from one and the same ionization by a spreading of its effect. The reports and demonstrations of a large series of separate investigators—Bauer, Fabergé, Demerec, Camara, Catcheside, Oliver and Belgovsky—in one way or another agreed with or led to one or more of the same conclusions, although some investigators had until then held contrary views. Further light was thrown on chromosome structure and on the changes to which it is subject, in a special evening lecture by Metz, recounting his notable findings in Sciara.

A considerable group of papers analysed t
special, though not absolutely distinctive, p
perties of heterochromatic regions of chromosom
In this connexion, further illustrations were giv
of the high breakability of these regions by Ka
mann, Camara, Prokofyeva and Sidorov, and
their somatic variability (correlated in relat
cells) in respect to manner of chromatin staini
manner of aggregation of chromonemata and ge
functioning. It was noted that all these propert
extend, although to a degree diminishing w
distance, beyond the originally heterochroma
regions into regions lying near to them in
chromonema, by a kind of 'position effect' (Schul
Prokofyeva, Panshin, Khvostova), and the i
portant new point was brought out that the var
tions in staining—which, as proved by Casperss
and Schultz's studies of ultra-violet absorpti
spectra, fairly represent nucleic acid distributio
and the variations in gene activity are correlat
with one another. Evidence was also adduced,
Prokofyeva and by Kaufmann, that small int
stitial regions having some degree of hete
chromaticity are scattered rather widely througho
the chromatin, and often coincide with regions th
apparently originated relatively recently as dupli
tions (which suggests that genes may become hete
chromatic by a kind of denaturizing degeneratio

Analysing the mechanism of gene mutation
the basis of a great series of experiments, Timofée
Ressovsky brought out its causation (1) by
dividual atomic activations, apparently resulti
from the accidental peaks of kinetic energy
thermal origin, as well as (2) by individual ioni
tions, resulting from radiation. The dependen
on single ionizations was further strengthened
Rai-Choudhuri's finding that even radiation of
tensities so low as 0·01 r./min. (a hundred tim
lower than the lowest previously used in su
work) is so effective, ion for ion, as radiation
higher intensities. At the same time, the generali
of the gene mutation effect of radiation w
strengthened in another important way, by
definite extension to mammals (mice). in expe
ments of P Hertwig.

---

* Although the Russian geneticists had withdrawn and most of the Germans had left before the time for their addresses, their abstracts had already been submitted, and in this Section the policy was followed of reading all such papers *in absentia*. They are accordingly included in this report, although only the papers of official members will be printed in the *Proceedings* Also included here are papers given in joint meetings of this and the next Section.

In earlier work, no dependence of the frequency f the gene mutations upon the closeness of spacing f the ions within the radiation-paths could be letected, but newer work by Timoféeff-Ressovsky nd his collaborators, reported at the meeting, uggested that a perceptible influence of this kind night be found by the use of the extremely closely paced ions resulting from some neutron radiation. f so, it should be possible to estimate the 'sensitive olume' for a gene mutation, that is, the amount f contiguous space occupied by material so constituted that one ionization, occurring anywhere vithin it, is capable of producing some one or nore of a given series of alleles. Similar work, tilizing the frequency of chromosome breakage nstead of that of gene mutations, was reported y Marshak. In this connexion, however, it should e noted that if, as seems likely, only a small roportion of the ionizations occurring within the egion in question actually resulted in the effect ooked for, this method would tend to lose its fficacy. Moreover, we have no basis for identifyng the volume or area in question with that of he gene or chromonema itself.

In addition to the seemingly simple thermal ffect of van t'Hoff type, above-mentioned, there vere shown—by Plough, Timoféeff-Ressovsky, Kerkis and Zuitin—to be decided increases in mutaion frequency attending the abnormal physiologcal states of organisms subjected to temperature hanges too rapid or too extreme for the organisms o adjust to them. This makes the search for special hemical influences affecting gene mutations seem nore promising, despite certain negative results eported by Auerbach with carcinogenic subtances. The sensitivity, as well as the intricacy, f the chemical complexes conditioning mutation vas further evidenced by the strong dependence f the general mutation frequency upon the enetic complex present, as reported by Plough nd by Tiniakov, and more especially by observaions of Rhoades and of Harland showing certain normous and highly specific mutational effects on articular genes, not previously known as 'mutable enes', by other particular genes and geneombinations.

The series of papers dealing with the production f mutations by ultra-violet light showed the otable progress made in this field since the last ongress. It was shown by Stadler that the curve epresenting the effectiveness of different wavelengths in producing gene mutations and deficiencies in maize pollen begins at about 313 mμ and rises to a peak at 254 mμ, declining thereafter. This is suggestively similar to the absorption spectrum of nucleic acid and quite different from that of protein. Both Hollaender, working on fungus spores, and Knapp and Schreiber, on spermatozoids of Sphærocarpus, reported results substantially similar to this, although their peaks of mutational effect (as well as of directly lethal effect) were at 265 mμ, which corresponds more exactly to the absorption peak for thymonucleic acid. In Hollaender's work, however, there was also a secondary peak, at 238 mμ; and another peculiarity in his results (one suggesting differential sensitivity of different spore stages) was a falling off in the mutation frequency of surviving individuals at very high doses.

In Stadler's work, a basis was found for drawing qualitative distinctions between several different classes of radiation effects. Thus, the frequency of abortive embryos at different wave-lengths, unlike that of gene mutations and deficiencies, failed to follow the nucleic acid curve, as it showed too high frequencies for the shorter wave-lengths. While these abortive embryos may after all represent some kind of non-genetic effect, the same cannot be said of sectional rearrangements of chromosomes (translocations). Stadler found that the latter were not produced by ultra-violet light, or were produced with a markedly lower frequency than by X-rays of the same gene mutation-producing strength.

This result, which was corroborated for Drosophila sperm by experiments carried out by Muller and Mackenzie, gives some ground for supposing that ultra-violet does not act by breaking the chromosomes, and that therefore gene mutations may not consist merely of linear rearrangements of ultra-small size, involving 'intragenic' breakage and reunion. The latter idea, which is not yet actually refuted, would have tended to make the concept of the segmentation of the chromosomes into discrete 'genes' a mere matter of verbal convenience. Possibly connected with the same series of problems was Stadler's further finding that the gene mutations produced by ultra-violet are far oftener 'fractionals'—that is, confined to one of the chromatids derived from a given treated chromosome—than are those produced by X-rays.

For the first time in the history of genetics congresses a session was included on virus and protein studies in relation to the problem of the gene. A peculiar case of non-chromosomal, probably virus, 'inheritance' in Drosophila, was reported by L'Héritier and Teissier. As was brought out by McKinney, by Gowen and by Kausche, viruses, now known to be crystallizable nucleoproteins, have the distinctive combination of properties characteristic of genes, namely, mutation and (despite mutation) self-duplication, thus substantiating the concept (Muller, 1921, 1926) that viruses represent relatively free genes, and that the gene constitutes the basis of life.

An illuminating account was given by Astbury of his and other modern studies of the chemical structure of viruses and other proteins, with especial consideration of those features which might help to explain the gene's property of mutable self-duplication. He, as well as Caspersson and Schultz (who reported an increase of nucleic acid during periods of growth, both for chromosomes and for cytoplasm), directed attention to the role which nucleic acid may have in this process. The significant fact was reported by Astbury that the nucleic acid spacings are of the same magnitude as those within the protein (polypeptide) chain, a feature which would allow the nucleic acid to unite in parallel with the protein and so perhaps to serve as an intermediary in its synthesis. The paper of Mazia also was of interest in this connexion, since it showed that in salivary chromosomes the framework is not disintegrated by digestion either by pepsin or by nuclease, though it is by trypsin; hence it probably consists of protamine or histone chains, bound together laterally in some other way than by nucleic acid cross-connexions. Other chemical studies nuclear material were reported by Gulick, whic among other things cast doubt on the presence iron in chromosomes, thus bringing their compos tion closer to that of the virus.

Our present knowledge of the internal structu of the tobacco mosaic virus particles, as disclose by the pioneer X-ray diffraction studies of Berna Crowfoot *et al.*, was described by D. Crowfoot a well as by Astbury. It was shown that in thes rods, which are 15 mμ thick and at least ten time as long, the smallest possible chemical unit—tha associated with one nucleotide—must contai about fifty-four amino-acid radicals, althoug there may be a geometrical sub-unit as small a one eighth of this volume (that is, about 1 m each way). But these units (or sub-units) a grouped according to a regular pattern into larg aggregates, about 7 mμ long, and the latter in tur are grouped in a regular way to form the aggregat of high order—the virus rod itself. The globula protein insulin, as well as the fibrous proteins. a show elementary units of about the same size, bu the mode of aggregation varies both with th protein and with the conditions (pH, amount o water, etc.) under which it is being kept. Thu this type of analysis is already bridging the ga between the structures of the chemist and thos of the microbiologist and geneticist.

A series of special conferences were held o problems of the gene, presided over chiefly b J. B. S. Haldane. These were very well attended At these 'gene conferences' many of the report of those unable to attend were read, and many o the above and related questions concerning gen and virus structure and gene mutation were subjected to animated and searching discussion.

CYTOLOGY

By Dr. C. D. Darlington

PERHAPS the most significant feature of the cytological discussions was the difficulty of separating them, except in an arbitrary way, from the discussions of experimental breeding. This was due to three general trends. First there was an increasing use of the direct study of meiosis as a basis of genetic prediction and as a means of testing the reproductive methods of particular species. The work of White and Kolle with sex chromosomes and of Huskins and Newcombe with the relations of chromatids at chiasmata were examples of the one, the studies o Levan on Allium, of Cleland on Œnothera, and o Janaki on Saccharum were examples of th other.

The second trend was the increasing applicatio experimental methods to cytology, both to lve problems that are of immediate cytological terest and to produce results of practical impor- nce in breeding. The different kinds of upset duced in cell-division are of interest in both ays. The diplochromosomes produced by arber's heat treatment represent the mode of ction of colchicine described by several workers giving rise to polyploids. The third trend was he increasing linkage of Drosophila genetics with minute study of salivary chromosomes, so that e found leading geneticists in America and ngland, like Demerec and Muller, offering papers mbodying accounts of the breakage and reunion chromosomes related to the direct observations cytological workers like Kaufmann and Bauer. This last development showed its widest bearings the kind of population study described by obzhansky. The interlocking action of gene hange and chromosome change now discovered field genetics is evidently making it possible bring the scheme of variation in Drosophila to the closest relationship with plant cytology. t gives the whole body of genetics and cytology a unity which is enabling them to be used as a joint tool of evolutionary research.

A word should be said of the technical side of cytology. The great advances of recent years were represented by an extensive microscope demonstration of chromosomes of Drosophila, Zea, Osmunda, Paris, Trillium, of various Orthoptera, and of Mammalia including man. A show of photomicrographic lantern slides brought home these exhibits to a larger audience and made it possible to compare the merits of different new methods of treatment.

A combined gene and chromosome session opened by Dr. W. T. Astbury was devoted to protein and virus studies in relation to the gene. It showed the results of applying new technical methods in protein and virus chemistry. It also showed that these, combined with the study of X-ray mutations on the genetical side and the use of ultra-violet photography and microchemical tests on the cytological side are producing a practical convergence of biology and the physical sciences, a convergence that will probably mark the beginning of a new epoch.

PHYSIOLOGICAL GENETICS

By Dr. C. H. Waddington

ONE of the most active branches of genetics at the present time is the study of the ways in hich genes affect developmental processes, and he section devoted to physiological genetics had a ll and interesting programme. The problem of enic action is so complex and many sided that ery many different methods of approach are ossible, and examples of most of these can be ound in the papers presented at the Congress.

The embryological approach was well exempli- ed in a paper by Landauer, in which he reviewed he correlated effects on different organs which re found both in fortuitous teratological specimens nd also in abnormalities which are known to be ependent on genes. He suggested that many of hese phenomena can be explained by the hypo- hesis of a general deleterious effect, often on the rowth-rate, acting at a period which is critical or a certain set of developmental processes. A eneral embryological approach of a rather different kind was presented by Waddington, who discussed the relation of genes to developmental processes of the kind exemplified by the organizer reaction.

The importance of nuclear factors in particular steps of differentiation was analysed in more detail by Baltzer, who gave a summary of his well-known and important work on bastard merogons, in which an enucleated egg of one species of newt is fertilized by a sperm of a different species. He showed that some tissues are able to develop to late embryonic stages, while others die presumably owing to disharmonies of nucleus and cytoplasm during particular processes of differentiation; still other tissues, such as some of the anterior mesoderm, while able to live, lose their normal power of inducing other organs—in this instance the balancers and gills. Similar studies of the importance of particular elements in the nucleus were reported by Poulson in his studies of the abnormalities produced by total absence of certain genes (homozygous deficiencies) on the early development of Drosophila.

Several reports dealt with gene effects on processes which are chemically more or less defined. Thus we had further chapters in the important and rapidly developing researches of Price, Lawrence and others on flower pigments, and Beadle, Ephrussi and others on Drosophila eye colours. Perhaps the most important new contribution in this field was a fresh study by Sewall Wright of guinea pig coat colours, which he dealt with in a preliminary way many years ago. He was now able to suggest a scheme for the relations of the numerous genes which are known, and to present a mathematical theory of their quantitative interactions.

Quite a different method of approach to the same problem was reported by Schultz and Caspersson, who, by studying the chromosome itself, obtained data which allow of some speculation as to the chemical changes occurring under the immediate influence of genes. Owing to their strong absorption in the middle ultra-violet, the distribution and changes of the substances belonging to the nucleotide group can be followed in the living cell by spectrophotometric methods elaborated by Caspersson. It is found that in the nucleus the nucleic acids seem to be indispensable for the development of chromosomes, and that they are synthesized mainly in earliest prophase just before the chromosomes split. Schultz studied translocations of parts of the heterochromatic regions of the chromosomes, which are rich in nucleic acid, into normal euchromatic regions i Drosophila. In certain of these translocations th adult flies show variegation for characters affecte by genes near the position of the break in th chromosome, as though frequent mutations of th genes had occurred in late stages of development Schultz showed that this variegation is correlate with cytological effects in the salivary chromosome bands corresponding to the variegate genes; these effects ranged from appearance o excess nucleic acid to the assumption of a heterochromatic character and finally apparent disappearance. It is suggested that the appearanc of excess nucleic acid is correlated with an inactivation of the gene as a developmental agent The nucleic acid metabolism can be follow somewhat further, since it is found that th presence of extra heterochromatic material (fo example, supernumerary *Y*-chromosomes) affect both the degree of variegation, the cytologic correlates of variegation mentioned above, an also the nucleic acid content of the cytoplasm. Th different types of nucleic acid occurring in chromosomes, nucleolus and cytoplasm can be determined spectroscopically and suggestions made as t their functional relations with the fundamenta processes of gene action and gene reduplication

It is possible, as Schultz suggests, that we may i this way obtain some insight into the changes o gene activity in different chromosome regions i the different tissues, which may provide mechanism for the primary differentiation of th nuclei in development.

ANIMAL BREEDING IN THE LIGHT OF GENETICS

BY DR. J. E. NICHOLS

THE opening session was devoted to general considerations of animal genetics. H. C. McPhee described the United States Department of Agriculture's long-term inbreeding projects with pigs, sheep, and poultry, and the emphasis now being laid upon measuring the more complex physiological characters; and in reviewing the work at Wiad, Sweden, G. Bonnier mentioned the economy in numbers of experimental animals made possible by the use of monozygotic twins, and the similarity to plant breeding techniques now being obtained with poultry, where th mixed sperm from many males can be used i artificial insemination. W. K. Hirschfeld an G. M. van der Plank struck notes for many succeeding speakers in directing attention to th distinction between frugal and less frugal breed and families relative to production, and to the nee of precise studies on differential demands upo the components of a ration. Their advocacy o the progeny test was pressed further by A. L Hagedoorn, who suggests restricting to *élit* clei' of breeding stock the function to be sole genitors of their kind.

The section got into its stride of discussion on gust 24 in an all-day session on live-stock provement in tropical and relatively low tritional plane conditions. J. H. R. Bisschop ve a comprehensive account of the interesting technical studies on Afrikaner, imported, and de cattle being conducted in South Africa, with objectives of defining a type and performance ted to semi-arid conditions and of assessing the generation of the pure imported types therein. ing the Australian Merino sheep as an example, E. Nichols discussed the practical difficulties of usting type to environment when artificial ection is heaviest in more favoured and natural ection in poorer conditions, where commercial duction is expected. A. O. Rhoad described experimental determination of adaptability of tle to unfavourable conditions in America by ans of body temperature reactions, and revealed etic differences in respect of physiological racters; while Manresa and his collaborators nonstrated significant differences in the hæmobin and other constituents of the blood in tle in relation to atmospheric temperatures d thereby to adaptability to the local environnt) in the Philippines. The economic and ial backgrounds of breeding problems in the imal industries in countries from the Gold Coast Madras were presented in several communicans, and R. B. Kelley lodged a strong claim for importance of ecological and economic studies prerequisite surveys to constructive breeding licies in tropical Australia. Later, G. Pontecorvo essed the influence of agricultural conditions on licies of selection in beef and draft cattle in scany.

The use of artificial insemination as a rational hnique in animal breeding was discussed in a ecial session at which were described the methods ployed, and their accompanying problems, in ly, the United States, Rumania, Kenya, and at row. The necessity of adequate criteria of sperm iciency was strongly stressed by J. Edwards d A. Walton in presenting an account of recent estigations at Cambridge in which the respiran rate of sperm has taken a prominent and omising position.

Statistical safeguards and interpretations in netical experiments with animals and in the analysis of records of performance and progeny tests were discussed notably by F. Yates and J. L. Lush, not only in formal papers, but also in relation to other contributions, especially those on the inheritance of milk yield. This problem, of great practical importance, stimulated one of the most effective discussions of the section, in which particular attention was given to the question of persistency in lactation. The lability of the several phases of a lactation in response to environmental influences of nutrition, management, etc., leads to difficulties in evaluation of records, but emphasizes the need for detailed analysis as well as ultimate resolution in terms of the physiological processes affecting the component parts of the curve.

In other sessions lethal factors and defects in large animals and genetical characters in small animals were discussed; F. W. Dry presented a case of linkage between horns and abundance of halo hairs in New Zealand Romney sheep, and R. C. Bamber an interesting instance of the operation of a time factor in the inheritance of white spotting in cats.

Breed differences and the recognition of the physiological substrata received further prominence in the session on poultry genetics when F. B. Hutt presented evidence of differential reactions and performances, A. W. Greenwood advanced indications of a genetical control of egg-laying persistency, and A. Ghigi's contribution on cerebral hernia in the fowl evoked discussion on the relationships of skull form, 'crest', and hernia.

Again, in the sessions concerned with nutrition and genetics, and with pig breeding, the same fundamental approach was manifested; as in the demonstration by C. P. McMeekan and J. Hammond that the plane of nutrition exerts a profound effect upon not only general form but also the growth components so that the direction, as well as the possibility, of selection is influenced by environmental thresholds. That this aspect of the problem of livestock improvement deserves further scientifically determined discrimination at all stages of growth and in regard to practical breeding policies was emphasized by H. P. Donald and by H. R. Davidson.

It may be said, in fact, that the central theme throughout the proceedings of this section was the evaluation of genetic differences and responses to environmental conditions in relation to the requirements of practical husbandry.

PLANT BREEDING IN THE LIGHT OF GENETICS

BY DR. K. MATHER

THE following conclusions may be drawn from the section of plant breeding in the light of genetics: first, that genetics and cytology can afford valuable assistance to the plant breeder, and secondly, that the geneticist needs a better understanding of the problems of plant breeding, and the breeder of the possibilities of genetical research, before really fruitful collaboration will be achieved.

The breeder requires, for example, detailed information about the mode of reproduction and the cytological behaviour of his material. Cytology and genetics can and do give him such information. But he also needs very detailed knowledge of the inheritance of quantitative characters, and this the geneticist cannot at present supply. It is highly significant that in horticultural breeding, where genetics and cytology have most fully proved their value to breeding programmes, the geneticist is also frequently a breeder. The breeding problems can in such cases be attacked immediately with the full resources of the genetics, and on the other hand, the value of any new genetical technique for breeding work is immediately appreciated. As a case in point, Crane and Thomas have encountered the necessity for determining the mode of reproduction of Rubus species, and have been able to obtain the necessary information by a series of simple genetical and cytological observations. There is also collaboration between breeders and geneticists interested in maize, and for the past fifteen years maize breeding methods have been developed at a rate far exceeding that found in any other cereal crop, as described by Lindstrom, Singleton and Jenkins. The problems of the root-crop breeder closely parallel those encountered in the case of maize, and in overcoming them Rasmusson adopts a similar technique based on like genetical experience.

It is in the field of self-fertilizing cereals that there has been least collaboration, and it is here that opinion is most sharply divided on the question of the practical value of genetical work. Cytology has provided essential information about t causes of sterility in wheat species crosses and Triticum-Agropyron crosses, but it is clear th the real need of the cereal breeder is guidance his varietal crossing and selection programm This guidance can only be given when mo genetical research has been done on inheritan in quantitative characters.

Perhaps the most difficult and least develop aspect of plant breeding is the production of wh are essentially new species of crop plants hybridization and polyploidy. The discovery the action of colchicine in bringing about chrom some doubling has given a stimulus to research this field, as shown by the number of papers the subject. It is, however, too early to ass accurately the practical possibilities of colchici treatment. In this connexion, also, the study the origin of our present cultivated plants is prime importance in indicating how such n forms might be made. Mangelsdorf's analy of the origin of maize materially adds to o knowledge in this direction, besides affordi another example of how genetical analysis c be used in the solution of an evolutiona problem.

All breeding work involves variety trials, a both these and the development and use of t theory of quantitative characters will requi rather complex statistical analysis. The use statistics in plant breeding was the subject of joint meeting of this and the statistics secti opened by Yates. It was apparent that the f benefit of statistics, as of genetics, has not y been realized in plant breeding.

Though the task of organizing genetics, cytolo and statistics in the service of plant breeding unquestionably difficult, the Edinburgh meetin especially that of Frankel's committee of pla breeders, have been of service in showing not on what has been done but also where the difficulti are to be found. Further meetings of the sa kind should be of even greater value.

HUMAN GENETICS

By Prof. R. Ruggles Gates, F.R.S.

HUMAN genetics was well represented at the
Congress. Abstracts of a large number of papers
re prepared, but like other sections their pre-
ntation was somewhat deranged by the approach
war. At different sessions the section discussed
h topics as mental inheritance, feeble-minded-
ss, blood groups, statistical methods in human
netics, selection in human populations, twinning,
rmal and abnormal human characters.

F. Lenz showed that the twin method and the
relation method may give different results as
ards the relative shares of heredity and environ-
nt in the formation of a character. Dr. R. J. A.
rry presented the results of a study of mental
ect in 163 families with parents of normal
ntality and 202 families in which the parents
re mentally defective, insane or of very low
ntality. Mental defectives were twice as
quent in the second group. The problem was
arded as one of the inheritance, not of mental
tes but of normal standards of growth. Dr.
ugger agreed that the majority of mental de-
tives show only retarded mental development,
l concluded from the investigation of 2,380 sibs
t there is a unified recessive inheritance,
ble-mindedness and imbecility generally appear-
together.

Dr. Fraser Roberts pointed out that most
ectives fall at the minus end of the normal
tinuous series and he believes there is multi-
tor inheritance, the low-grade defectives form-
a very heterogeneous group. He concludes
t there are a number of genes, any pair of
ich can determine idiocy or imbecility, abnormal
ceptibility to non-genetic influences frequently
ng present. From a study of 3,400 school
ldren by intelligence tests he concludes that
mal intelligence is also graded and very largely
ermined by multifactor inheritance.

D. K. Henderson recognized a hereditary basis
the manic-depressive and schizophrenic states
l emphasized that a eugenic programme must
largely educational. Helgi Thomasson, on the
er hand, from a nine years study of manic-
ressives in Iceland, was doubtful about the inheritance element. He diagnosed 859 cases of manic-depressive psychosis, only 15 per cent of whom were treated in hospital. Probably his criteria of diagnosis differed from those of others, and perhaps the general climatic conditions in high latitudes may also account for the high incidence. Dr. F. J. Kallmann emphasized that the practical goal of human genetics is the determination of the various physiological, constitutional and dispositional factors governing the phenotypical manifestation of hereditary predispositions and the description of their structural equivalents in proper morphological terms. From a study of 500 pairs of schizophrenic twins and their families, he concludes that the schizophrenic genotype is specific, autosomal and probably single-recessive. Its manifestation is inhibited in about one quarter of the homozygotic taint-carriers by the aid of a strong constitutional resistance or by the lack of furthering dispositional factors.

In a discussion of rare psychological defects in a population, G. Dahlberg concluded that the effect of selection on its incidence is very small, that the effect of prevention of cousin marriage is also small, but that the breaking up of isolates in the population is most important.

Various workers have shown that an injection of cardiazol produces epileptic spasms in animals and man, but a hereditary epileptic will have fits after a smaller dose than a non-hereditary epileptic or a non-epileptic. Hans Nachtsheim finds that a strain of white Vienna rabbits has a gene, X, for leucism and an allele Xe which causes increased liability to spasms, X being dominant over Xe. Among 250 animals given minimal doses of cardiazol, 83 per cent of the homozygous $XeXe$ rabbits but only 3 per cent of normal controls react with spasms.

Pick's disease was studied by J. Sanders in a family with sixteen affected members. The symptoms begin at 40–50 years of age, so that early diagnosis is important. The inheritance is dominant, and it was found that persons who gave queer answers in the ink blot tests developed the disease twelve to eighteen months afterwards.

In a study of twenty-nine families showing tooth deficiency, Barbara Burks found evidence of linkage with hair colour. D. J. Finney also obtained statistical evidence of linkage between allergy and the *ABO* blood groups ; while Munro, Penrose and Taylor, from analysis of twenty-five sibships, found an indication of linkage between the blood groups and phenylketonuria.

As regards disorders, R. C. Robb reported on 100,000 hospital patients, and D. P. Murphy on 935 malformed children studied in relation to birth order, sibs, maternal age, reproductive rate, etc. H. Madissoon cited cases of absence of kidneys (in the fœtus) conditioned by heredity. D. Ferriman found that oxycephaly and acrocephalosyndactyly are dominant conditions, probably allelomorphic, and that a third allele may be acholuric jaundice. Race, Taylor and Vaughan showed that a latent form of the latter disease can be demonstrated investigation of the blood. Dr. I. Lundholm sho that hypochromic anæmia, which is common women in Sweden, is conditioned by a domin gene which prevents the normal absorption of i through the digestive tract.

J. B. S. Haldane pointed out that nat selection in man may act through survival, sex selection or reproductive selection (fertility), that in theory four types of selective process be distinguished, involving slow or rapid selec of genes, selection of heterozygotes or eliminat of rare mutants.

P. J. Waardenburg showed that the *X*-chro somal eye defects, dystrophia retinæ pigment and extraocular nystagmus can be inherited dominant or recessive sex-linked or dominant recessive autosomal characters.

GENETICS IN RELATION TO EVOLUTION AND SYSTEMATICS

By Dr. W. B. Turrill

THE Organizing Committee of the Congress, at the suggestion of the Association for the Study of Systematics in Relation to General Biology, arranged for a special section to be concerned with the wider aspects of genetical research. In spite of the numerous difficulties caused by the international situation both in arranging and carrying out the programme, the results not only justified the attempt but showed the desirability of making a general rule to include in specialist biological congresses a section devoted to overlaps of the special subject with other branches of biology.

The programme of the section was so arranged that papers were grouped under the following general titles : Hybridization, Comparative Genetics and Evolution, Micro-evolution, Experimental and Wild Populations, and Polyploidy and Reproductive Mechanisms. In the plenary session of the section, Th. Dobzhansky dealt with the genetic structure of natural populations. He urged that "according to the genetic theory the pressure of the evolutionary factors, such as mutation, selection, isolation, and migration is constant and unrelenting. A living species can hardly remain static for any length of time. It is a task of investigator to observe evolutionary changes only *post factum* but also in *statu nascendi*, nature as well as under laboratory condition There is a hidden field of variation, detectable through observations on the phenotype but o by genetic and cytological means, and this m engage the attention of students of evolution mechanisms. The main part of his paper de with *Drosophila pseudo-obscura*, and it was sho that this is a dynamic species of local colon which can pursue, within certain limits, indep dent evolutionary courses. Only seconda through migration and selection of superior ge types formed in such colonies can the texture the species as a whole become gradually alter

G. Tischler, under the (translated) title the "R of Chromosomal Race Differences in Systemat and Plant Geography", stated that at least 4 wild cœnospecies of Angiosperms are known whi contain races with chromosomal differences. Ma species become capable of surviving in a climatica unfavourable environment through polyploi but within these species many type plants ha mained diploid. Numerous species have become eeds with a world-wide distribution, but their ploid races have only a local significance. Allolyploids may inhabit wider areas than either rent. Polyploids may develop a perennial habit, pomixis, or seasonal dimorphism.

J. S. Huxley, in a general paper on "Systematics Relation to Genetics", gave a valuable summary f the tendencies of modern taxonomy, illustrated y many examples. He showed that the progress f taxonomy itself, and its contacts with other ranches of biology, are converting it into the asis of the study of evolution in action. In the rst place, cytogenetic analysis is shedding light n particular taxonomic problems; secondly, xonomic advance is suggesting important quesons for experimental analysis; and thirdly, a mbination of all lines of approach is increasing oth the scope and the precision of the general rinciples underlying taxonomy and making it ossible to forecast the course of differentiation nd evolution in different kinds of taxonomic roups. It is not only cytology and classical enetics which are needed to co-operate with xonomy, but also ecology and embryology are qually essential.

W. B. Turrill considered "Taxonomy and Cytoenetics in Plants" and pleaded for close co-operaon between taxonomists and cytogeneticists. He lustrated the most desirable lines for such cooperation by examples of problems of mutual terest under the following headings: classificaons of characters, degree of correlation of charcters, constitution of taxonomic groups, the udy of polymorphic groups, geographical and ological problems, hybridization in Nature and xperiment, problems of apomixis, problems of hylogeny, and general suggestions.

S. C. Harland read a paper under the title "Genetical Studies in the Genus Gossypium and their relation to Evolutionary and Taxonomic Problems". Within the widespread species of this genus in both the Old and New Worlds he traced the consequences of isolation for several millions of years. Species crossing and the study of their cytology in Gossypium has led to the accurate delimitation of the genus, has shown that species may be regarded as systems of modifiers, has revealed the taxonomic position of species in relation to other species, and has proved that species intercrossing results in the disintegration of the coordinated modifier systems possessed by each; it has shown that geographical isolation causes profound genic change, has indicated that genes may become mutable when transferred to the genetical background of other species, and has suggested that the number of alleles at a given locus differing only slightly in their reaction with the genetical background is probably large.

It is impossible in this article to deal with contributions to the ordinary meetings of the section except in a very brief and most generalized manner. The recognition of much more hybridization in the wild amongst animals than has usually been admitted by zoologists was stressed in several papers. The importance of population studies in throwing light upon the actual mechanism in evolution was also emphasized The geographical distribution of 'races' in both animals and plants is obviously receiving increased attention and proving a connexion 'between genes and geography'. The wide occurrence of polyploidy and apomixis in plants is being shown to be one of the causes which make it difficult to accept the species as a clear-cut taxonomic unit.

GENETICAL ASPECTS OF GROWTH, NORMAL AND ABNORMAL

By Dr. A. Haddow

THE fundamentals of this subject were outlined in a paper by E. B. Ford, who demonstrated ow growth may be determined genetically by the ost diverse means. Thus it may be under the ontrol of a single factor-pair, or very numerous genes, approximately equal in effect, may cooperate. Again, while the genetic situation can influence cell-size or cell-division directly, the effect on growth is frequently indirect. For example, genes controlling the endocrine glands will modify total body size in mammals, as in recessive dwarfing in mice due to a factor-pair affecting the development of the anterior pituitary. Dr. Ford further discussed (1) the production by heterosis of increased size in the offspring of a wide cross, and (2) excess or reduction in hybrid size caused by mal-adjustment of the gene-complex. Similar considerations apply to differentiation, as in the case of a sex-linked factor producing dominant black-spotting in Platypoecilus and tumour formation in the hybrid between this and another form (Xiphophorus).

In a discussion of dominance in spontaneous cancer, P. A. Gorer dealt with the genetic basis of the inheritance of lung cancer in mice, mentioning evidence that the appearance of lung tumours is conditioned by three or four genes with additive effect, the degree of dominance thus depending upon the number introduced by the high-cancer parent. In those cases where the onset of tumours is delayed in the heterozygote, he regarded it as probably incorrect to speak of a change of dominance with age (Bernstein), since it is likely that the reactions preceding tumour emergence simply occur more slowly in the heterozygote.

Considerable interest centred round the interplay of genetic and environmental factors in the origin of different cancers. According to N Dobrovolskaia-Zavadskaia, the failure of external carcinogenic agents to produce mammary cancer in mice, even in strains of high susceptibility, indicates that the onset of such tumours is almost entirely dependent on genetic constitution. On the contrary, sarcomata and squamous-cell epitheliomata appear to depend pre-eminently on environmental influences, a view confirmed by W. F. Dunning and M. R. Curtis when they reported that variation in the concentration of a chemical carcinogen is much more effective in influencing the probability of malignant change than is the genetic nature of the host. In another paper on the effect of genetic constitution in determining the response to carcinogenic agents, G. M. Bonser described the gradation of tumou response by male mice to œstrogens as reflecti the ability of the females to develop spontaneo mammary tumours, although when castrat females of high-cancer strains were tested wi œstrogens, their ability to develop mamma cancer was reduced.

In a communication dealing with spontaneo and induced tumours in eight inbred strains mice, H. B. Andervont stressed (1) the correlatio between the susceptibilities to spontaneous an to induced pulmonary tumours, and (2) the absenc of any correlation between susceptibility to th induction of subcutaneous tumours by carcin genic hydrocarbons and susceptibility to spo taneous breast tumours.

Other contributors included G. W. Woolley o reduction in the incidence of mammary tumours i female mice in parabiosis with males, and H. Bagg on his method for early selection in mi and rats, by forced breeding coupled with th prevention of suckling, of those individuals co stitutionally prone to the development of brea cancer. W. Cramer and E. S. Horning describe the association in inbred strains of mice betwee brown degeneration of the adrenal and the inc dence of mammary cancer, although L. Kreyber found no difference in the occurrence of brow degeneration in two homozygous lines, one man festing a high and the other a low yield of spo taneous mammary tumours.

R. J. Ludford discussed somatic mutation i relation to growth, while P. A. Gorer also examine the choice between this concept and "anomalou differentiation" in the origin of tumours. Auerbach reported work on various carcinogeni hydrocarbons in respect of their influence o mutation in *Drosophila melanogaster*. None o the compounds used produced any increase i mutation-rate, a result which could not be ascribe to insufficient substance, although it might con ceivably be attributed to factors such as tim allowed for action or penetration to the tissues.

PRINTED IN GREAT BRITAIN BY FISHER KNIGHT AND CO., LTD., ST ALBANS.

NEWS AND VIEWS

oyal Society Medal Awards

THE following awards of medals have been made y the president and council of the Royal Society : opley Medal to Prof. T. H. Morgan, For.Mem.R.S., irector of the William G. Kerckhoff Laboratories, alifornia Institute of Technology, for his establish- ent of the modern science of genetics, which has volutionized our understanding, not only of eredity, but of the mechanism and nature of volution ; Davy Medal to Prof. J. W. McBain, .R.S., professor of chemistry in Stanford Uni- ersity, for his distinguished work in the study of lloidal electrolytes, for providing the elements of e guiding theory, and for developing the subject ; ughes Medal to Prof. G. P. Thomson, F.R.S., pro- ssor of physics in the Imperial College of Science d Technology, London, for his important dis- veries in connexion with the diffraction of electrons matter.

gineers in War-time

THAT a special degree of responsibility falls on ose called to high office in a professional capacity in me of war was apparent from the presidential ldress of Sir Clement Hindley to the Institution of vil Engineers. Instead of devoting himself, as he d intended, to recounting the cultural history and velopment of the Institution, he found it more ppropriate to put before the members the picture had in mind of the duties now to be taken up by e Institution as a corporate body, and by its embers as individuals. The regular forms of its tivities being very largely curtailed by the exigen- es of war conditions, its first duty lies in the main- nance of high standards, both educational and actical, for the admission of members. This volves an active interest in the education and aining of young engineers and, as a matter of mediate concern, in conjunction with the colleges, e adjustment of curricula to war-time conditions. n the Institution, too, is placed the responsibility seeing that studies are pushed on as far as possible fore military service has to be undertaken, and at those with technical training are employed in itable units. In all this there is the ultimate fact importance that when the period of reconstruction reached, Great Britain will need a well-trained and ell-equipped body of young engineers.

THE second duty of the Institution is that falling individual members to contribute their experience d knowledge to the common stock of the pro- ssion, in which the part of the Institution will be publish in the *Journal* such contributions and the rrespondence to which they give rise. The third d main function to be conserved is that of giving ntinued support to those scientific organizations hich have undertaken research and investigation for the Institution. While certain portions of this work have to be suspended, the Research Committee remains in being in order to deal with problems suggested, and the resources of the Institution are held available for any work the Government may consider can best be carried out by its members. Sir Clement's final remarks may be quoted as a message to all engaged in the pursuit of science and its application : "We may be sure that when we have passed through the present ordeals, and have achieved the victory for freedom for which we are now fighting, there will be unimagined opportunities for applying for the benefit of the human race those advances in science which are even now taking place under the stimulus of war. It is necessary for all engineers to continue to keep abreast of developments in engineering science and practice, and so to fit themselves for this great work of the future."

Fuel Industry in Great Britain

COLONEL W. A. BRISTOW, on his installation as president of the Fuel Luncheon Club, spoke on modern fuel problems. After indicating the cost in foreign exchange of refined oil products and other material such as carbide, silicides, etc., which can be made in Great Britain, he mentioned other products capable of synthesis more or less directly from coal. From the products of the carbonization and gasification of coal he indicated that a great range of chemical products can be made, and, in view of Great Britain's adverse balance of trade, must be made. The obstacle, he said, is not lack of skill, knowledge or courage, but an absence of planning at the centre. Another deterrent is the financial system by which the 'financial whipcrackers' controlling public companies insist on immediate dividends and frown on efforts made in the national interest. He thinks the State should establish a 'Commercial Research Force' not merely for pure research but also to operate plants of capacity and bring processes to fruition. If these ideas are vitally important, it is only logical that the citizen should make his due contribution. There is another reason why an early start should be made in this direction. An effort should be made to prepare for creative work for the young men who return from the war. After the last war, the coal industry passed through tragic years. Moreover, none was more severely hit than the technicians left redundant by the cessation of munition manufacture. This time we should not leave the fate of returning armies to luck, but safeguard the future of the coal, oil and allied industries.

Projected Antarctic Expedition

A NOVEL feature of the new antarctic expedition which Admiral R. E. Byrd proposes to lead from the United States to the Ross Sea area is the snow cruiser which, according to Science Service, has been designed by Dr. T. C. Poulter of the Armour Institute of Technology. This mobile base is to be 55 ft. long and will travel on wheels 10 ft. in diameter. Propelled by petrol, it will have a cruising speed of twelve miles per hour and a top speed, on favourable surfaces, of twenty-five miles. Its range of action should be about five thousand miles. There are quarters for four men, a control cabin, engine room, machine shop, galley and laboratory. Supplies for a year can be carried. The scientific equipment of the snow cruiser includes seismic sounding outfit, gravimeter, and dip circle as well as survey instruments. The builder claims that this mobile base will allow more work to be done in one season than other expeditions have been enabled to do in several years. Its weight is not given but must be considerable, so that its range of movement will clearly depend much on surface conditions, which are always a deciding factor in any form of antarctic travel.

Arrival of the Reincarnated Buddha at Lhasa

THE veil of secrecy which for so long hid the religious life and ceremonial of the sacred city of Lhasa from European eyes may be said to have been lifted finally by the account of an eye-witness, accompanied by photographs, of the arrival in that city of the new Dalai Lama, the four-year-old child in whom, according to Tibetan belief, has been re-incarnated the living Buddha. The story is told in an article which is contributed to *The Times* of November 4 by a special correspondent. Although the essential features of the installation of a living Buddha reincarnated in the person of a small child destined to become a Grand Lama were reported by the Abbé Huc, who travelled in Tibet in 1844–46, it was on hearsay only, as the Dalai Lama of that day had already attained the age of nine years. The present account is fully confirmatory of Huc, but with much added detail. On October 7 the new Dalai Lama was met by the Regent at Rigya, two miles east of Lhasa, where he had rested for two nights, and was escorted in procession to the Peacock tent, which had been erected in the centre of a triple-line, square enclosure. There he was seated on a throne, covered with white silk and fronted with the emblem of the double thunderbolt, to receive the homage and offerings of scarves from the officials, headed by the Regent, and representatives of British, Nepalese, Chinese, and of the Lhasa Moslems, who filed before him, receiving his blessing from either both hands, one hand, or a tassel pendant from a silver rod. At the close of this ceremony, which lasted for about an hour, tea was brought for the Dalai Lama in a golden teapot, of which he partook from a jade cup after it had been tasted by a household official.

ON the following day the Dalai Lama entered Lhasa, the procession passing through the streets of the city to the sacred residence, the route, as on the preceding day, being lined with crowds of reverent spectators, monks and others, holding banners and auspicious emblems. One of the more interesting incidents recorded took place when, as the yellov palanquin in which rode the Dalai Lama, formin the centre of the procession, reached the entrance o a temple, it was met by the Oracle of Nechung in state of possession. A god who acts as the guardia of religion is said to enter into him, and when he i so possessed he dances with convulsive movement bending his body quickly to the ground, forward and backwards. He wore a high headdress of whit plumes over a golden crown, and brandished a swor and a bow. Similar devil-dances are characteristi of Tibetan Buddhism, more especially in the easter parts of the country, where primitive animistic form of belief survive in conjunction with the more orthc dox ritual. On this occasion the Oracle, described a a "terrible figure", rushed to the Dalai Lama' palanquin, and thrust in his head so that the spir within him could do reverence. The young Dal Lama, it is said, was quite unperturbed.

Pacific Entomological Survey

JUDGING from correspondence which has recentl appeared in *Science*, some misunderstanding as t the purpose and position of the Pacific Entomologic Survey has arisen. A brief statement relating to th Survey appeared in NATURE of January 29, 193 p. 196. Mr. E. P. Mumford, director of tl Survey, in connexion with the Hope Departmer of Entomology, University Museum, Oxford, h been for some years working out the collection with the co-operation of specialists in all par of the world. More than two hundred pape have already been submitted for publication i Hawaii and elsewhere. It is important to recogni that the work at Oxford was made possible b grants from the Leverhulme Trustees and the Britis Museum (Natural History); the name "Pacifi Entomological Survey" was used to maintain th continuity of the work, and will not be used in con nexion with the present investigations associate officially with Oxford. The only object in view is t obtain, and make known, facts which will help i elucidating the problems of the Pacific Islands; th Marquesan collections and certain other material no under the charge of Mr. Mumford will be deposite in the Bernice P. Bishop Museum, Honolulu, whe the final results have been obtained. To further thi end the Hope Department of Entomology of th University of Oxford, by means of grants from th University for five years from October 1938, fro the Royal Society and the British Association, an from private benefactors, is obtaining from sundr little-known islands in the Pacific, new collection which it is hoped will aid in elucidating problem revealed by the Marquesan work that Mr. Mumfor has been completing at Oxford.

Ancient Tests for Pregnancy

IN a recent paper (*Proc. Roy. Soc. Med.*, 32, 1527 1939) on this subject, Dr. H. P. Bayon showed th the existing translations of Egyptian papyri reveale directions for the performance of several tests fo pregnancy; some of the tests seemed superstitiou

ers were based on signs and symptoms, and a
could be described in modern terminology as
ormonal germination tests made with pregnancy
ne". Similar tests for pregnancy, fertility and
gnostication of sex are to be found in the Hippo-
tic writings, their survival for more than a thou-
d years indicating that there was some connexion
ween Egyptian and Greek medicine. These tests
also be traced in various medieval authors, such
Moscius, Trotula, Michel Scot, and Albertus
gnus, though they were modified in substance and
thod. At the end of the sixteenth century they
gan to be distrusted, though their practice has
en recommended even in recent popular works.
. Bayon maintains that the original Egyptian
t for pregnancy and its modifications, though
mingly absurd in theory and certainly erroneous
practice, represent the first diagnostic tests on
ord, while their employment throughout the
dle Ages and later indicates a persistent effort to
oly biological experimentation to the needs of
dicine. The Egyptian test was also a striking
mple of instinctive anticipation, which proved
t in the development of medicine, intuition pre-
ed practice, and was followed by understanding,
ich culminated in reasoned and demonstrable
owledge.

ence and Animal Welfare

s was noted under the above heading in NATURE
October 22, 1938, a committee was formed by
F A W (The Universities' Federation for Animal
lfare) in an attempt to bring scientific reasoning
some of the outstanding problems concerned with
welfare of animals, and a short résumé of the
posed functions of the committee was given. It
now possible to review the progress of the first
r, which has been distinctly encouraging. In
nexion with rabbit control, a grant was made
vards the costs of research upon ecological aspects
the problem, which is being carried out at the
reau of Animal Population, Oxford. The Preven-
n of Damage by Rabbits Act was promoted by
F A W. On Skokholm Island, off the Pembroke-
re coast, the Federation has participated in the
empt to carry out a wholesale cyanide fumigation
the warrens, and it is intended, if possible, to com-
te the eradication of the rabbits this winter and so
der the island suitable for farming. Another area
dication experiment is being supported in Corn-
l.

HE problem of anæsthetics for animals has
eived considerable study. It is felt that the
imals Anæsthetics Act of 1919 is in need of careful
ision, and the National Veterinary Medical Associa-
n has agreed to appoint a committee of experts to
iew the whole position of anæsthesia in animals,
l to make recommendations for the drafting of a
bill. Animal euthanasia has also been studied;
suggestion which is being discussed concerns the
sible use of drugs which, although potent narcotics,
e not been marketed for clinical use on account of their high toxicity or narrow therapeutic margin. While the war will almost certainly lead to a great diminution in the trading of pet animals, every effort is being made to provide, by educational means and otherwise, for an improvement in the care of such animals before and after purchase. The use of the electric goad for droving has been considered, and field tests are being carried out at an agricultural college to determine its efficacy. All who are interested in the work of the committee, are asked to communicate with the honorary secretary, A. N. Worden, at the Federation's headquarters, Gordon House, 29 Gordon Square, London, W.C.1.

Communications on Spectrochemical Analysis

OWING to the war, the publication of papers in the English language in *Spectrochemica Acta* is no longer practicable and Mr. F. Twyman, formerly English editor of the journal, has put forward a suggestion that there be an agreed single medium for the publication of such papers in England. Briefly, the proposal is that papers, articles, and notes on spectrochemical analysis should be sent to the *Journal of the Society of Chemical Industry*, and that if the communication deals with some special subject such as an application to botany, soil analysis, mineralogy, etc., the author should at the same time communicate to his own specialist society an abstract or companion paper dealing particularly with the application, while for details of the apparatus and spectrographic method reference would be made to the *Journal of the Society of Chemical Industry*. Should the 'specialist' portion of the paper be of preponderating interest, the main paper would naturally be submitted to the specialist journal, and an abstract or companion paper sent to the *Journal of the Society of Chemical Industry*. Manuscripts for the Society of Chemical Industry, which should in all cases be prefaced by a short introductory statement setting out in simple language the objects of the investigation and a synopsis of the results achieved, should be addressed to: Mr. T. F. Burton, Society of Chemical Industry, Clifton House, Euston Road, London, N.W.1.

A Sensitive Induction Magnetograph

A SENSITIVE induction magnetograph for measuring the time-rate dH/dt of the horizontal component of the earth's magnetic field is described by H. Nagaoka and T. Ikebe in *Scientific Papers of the Institute of Physical and Chemical Research* (Tokyo) of August 1939. The magnetograph embodies a design of a special shape for collecting the lines of force into a permalloy core enclosed in a cylindrical coil. A record is given of complicated magnetic disturbances caused by electric trams. Even at a distance of several hundred kilometres from a great city, the disturbances can be detected as minute ripples on the traces. The selection of an observing station for observing true geophysical phenomena is therefore a difficult problem. The observed effect of weak earthquake shocks is discussed. Apart from the purely mechanical effects of shock, there are probably some true magnetic effects due to the varying magnetic susceptibility of erupting lava (the subject of study being the Asawa volcano). The authors think that it may be possible to predict violent eruptions half an hour before they occur. It is also anticipated that the new magnetograph will provide data to test whether short-period disturbances of a few seconds' duration exist during magnetic storms. Provided that a suitable site can be obtained, the magnetograph has other applications in the study of the characteristics of the E- and F-layers of the ionosphere with respect to the height of origin of the current system producing the diurnal variation of the earth's magnetic field.

Apia Observatory

The annual report for 1935 of the Apia Observatory, issued by the New Zealand Department of Scientific and Industrial Research, bears witness to useful systematic work in several sections of geophysical research carried out at the Apia Observatory. The observations are grouped under terrestrial magnetism, seismology, meteorology, and atmospheric electricity. The meteorological observations include pilot balloon ascents for upper air data and the preparation of daily synoptic charts of the weather in the region of the South Pacific islands. A time service is also maintained. A glance at the meteorological records shows that conditions from the observer's point of view must often be difficult. The mean monthly temperature at 9h. usually exceeds 80° F.; there is much rain in some months, and relative humidity is invariably high. On January 16, 1935, a fall of more than 13 inches of rain was recorded, the total for the month being about 41 inches. Apia Observatory was established in 1902 in connexion with the German South Polar Expedition. The magnetic section of the Observatory was constructed in 1912, the seismograph installed in 1913, while the atmospheric electricity apparatus was housed in 1922–1924 through grants from the Department of Terrestrial Magnetism, Carnegie Institution of Washington. In 1921, the Observatory was formally taken over by the New Zealand Government, which has borne throughout the greater part of the cost of maintenance, although substantial annual grants have been made by the Carnegie Institution of Washington and by the British Admiralty.

The World's Largest Generating Station

Few engineers in Great Britain know much of the progress that is being made in the hydro-electric plant which is being erected at the Samara bend on the Volga by Soviet engineers. The *Electrical Times* of October 26 suggests that a study of the map of Russia will show that the lie of the land at this bend is ideal for the building of a huge hydro-electric plant. Imagine a hairpin bend of the river with the town of Samara containing about 60,000 inhabitants at the top of the bend. The two legs of the hairpin extend west and embrace a ridge of mountains. About thirty miles west of the town is a ravine in these hills, where a small tributary cuts through northward to join the Upper Volga at Stavropol. This would ma an ideal site for a power-house as the pipe lines wou short-circuit something like 75 miles of a falling riv The plant when completed is to have a generati capacity of 3·4 million kilowatts. We know that t six stations at Niagara have a total water power 1·6 million horse-power. Boulder Dam will have ultimate water-power of 1·3 kilowatts but main purpose is for irrigation, and as electric pow is only a side product it would therefore genera much less electricity than the Volga power statio which may therefore claim to be the world's larg power project. This is a case in which electric seems to be shaping the geography of a countr Much of the Samara power will be transmitted a probably, considering the immense distances to whi it will be transmitted, a voltage of 300,000 or mo will be used. Local industries will almost certain group themselves round the power station, as th have done in several places under Soviet control, a large new town will grow up.

Farm Forestry in the United States

A most interesting little booklet entitled "Fa Forestry" by W. A. Ross and W. R. Mattoon h recently been issued by the Office of Educati Department of the Interior, United States (Vo tional Division Bulletin No. 196, Agricultural Ser No. 52, U.S. Govt. Printing Office, Washingt 1939). The material in the bulletin has been p pared to provide teachers of what is termed vo tional agriculture with valuable subject-matt written in a practical fashion to enable them offer more effective systematic instruction on cert forestry work on the farm. The United States, it said, contains some 470,000,000 acres of land whi is classified as forest land. In addition there a several million acres which economists say are excess of what will be required for the production field crops and the raising of live-stock and whi are therefore available for forestry purposes. Timb is now a recognized crop in diversified farming p grammes. Much of the booklet may be read w interest in its application to Great Britain. T United States has, as is well known, some diffic problems to solve owing to excessive lumbering forest and excessive crop-growing on soils not appl able to such treatment. The so-called dust bowls ha shown the direction to which such over-utilizati leads. The hints given in this bulletin are theref of major importance to the farmer.

Land-grant Colleges in the United States

An English farmer remarked that, when he arriv in Honolulu in 1907, he was surprised to find t experts on the spot, ready to advise on forestry a agriculture, supply seeds and lend money on sm holdings. This is one result of the far-flung enterpri of the United States which appears in "The Lan grant Colleges", a paper-covered monograph prepar for the Advisory Committee on Education appoint by the President in 1936 (Washington, D.C.: G.P. 25 cents). The authors trace the rise and broadeni the movement from its beginnings in 1862. They not give instances of the actual working of the eme in any particular case, but its development a whole is clearly indicated with tables of statistics d comments. As the Acts which control the rking of the colleges are no fewer than nine, a rtain amount of friction with the State authorities inevitable. States differ in their resources and eds. But the authors agree that some Federal ntrol of the research to be made is wise. An Act 1935 arranged that Federal funds need not be natched" by the State contributions—a sensible ovision. Agriculture is the main subject. Home onomics appear to languish, from a table of time ent from 1928 until 1936. Experimental stations, in agriculture, can scarcely be arranged. But rrill's initiative in 1862 has certainly proved itful for the farmer, if it has not provided the eral education he contemplated. One difficulty to faced is the duplication of work already being done schools and colleges.

sistant for India at Kew

MR. C. E. C. FISCHER, assistant for India at the yal Botanic Gardens, Kew, is to retire shortly. joined the Herbarium in January 1925, while on lough preparatory to retirement from the Indian rest Service, which had been spent mainly in the dras Presidency. In the same year the death of . J. S. Gamble left the "Flora of the Presidency Madras" unfinished, and Fischer was charged with completion of the work. This involved the rking out of the seven families of Dicotyledons, Coniferae and the whole of the Monocotyledons. assistant for India in the Herbarium he was also ponsible for the identification of material from all rts of the Indian Empire, which during recent ars has been mainly from Burma, the Himalayas luding Southern Tibet, and the Madras Presidency. Mr. Fischer's retirement in December, he will be ceeded by Mr. K. N. Kaul, who has already spent arly six months at Kew. Mr. Kaul is a graduate the University of Lucknow, where he has worked der Prof. B. Sahni.

nouncements

PROF. J. GRAY, professor of zoology in the Univer-y of Cambridge, will deliver the Croonian Lecture the Royal Society on November 16 at 2.30 p.m. e title of Prof. Gray's lecture is "Aspects of Animal comotion".

DR. WILLIAM W. GRAVES, professor and director the Department of Neuro-psychiatry, St. Louis hool of Medicine, has received the Award of Merit St. Louis Medical Society for his studies on erited variations in relation to the problems of human constitution.

AN institute for industrial medicine and particu-ly for the prevention and control of diseases to dust will be opened shortly at Iglesias in rdinia.

THE community education section of the American Dietetic Association has recently published a bibliography of normal nutrition. It can be obtained at the office of the Association, 185 North Wabash Avenue, Chicago, at 10 cents a copy.

THE work of the Eugenics Society will be carried on at 69 Eccleston Square, London, S.W.1, during the war, and an emergency committee has been appointed, with full powers to act on behalf of the council. The quarterly publication of the *Eugenics Review* will be continued under the editorship of Dr. Maurice Newfield.

ACCORDING to a circular recently issued by the International Academy of the History of Sciences, the fifth International Congress of the History of Sciences will be held at Lausanne in September 1940, if the political and social situation of Europe permits. The permanent secretary of the Academy, M. Aldo Mieli, having now settled at Santa Fé in the Argentine Republic as director of the history of science in the University of Santa Fé, M. J. A. Vollgraff of Leyden has been appointed assistant secretary for Europe and the Mediterranean countries. The review *Archeion*, the official organ of the Academy, will henceforth be published at Santa Fé instead of at Rome as hitherto.

THE Finney-Howell Research Foundation, Inc., announces fellowships for 1940. This Foundation was provided for in the will of the late Dr. George Walker of Baltimore for the support of "research work into the cause of causes and the treatment of cancer". Fellowships carrying an annual stipend of 2,000 dollars are awarded for the period of one year, with the possibility of renewal up to three years; when deemed wise by the Board of Directors, special grants of limited sums may be made to support the work carried on under a fellowship. Applications for fellowships for 1940 should be made at the office of Foundation, 1211 Cathedral Street, Baltimore, Maryland, by January 1, 1940.

REFERENCE was made in NATURE of October 21, p. 714, to the British Association Research Committee on Blood Groups among Primitive Peoples; it should have been stated that the work referred to was done by, and under, Prof. R. Ruggles Gates.

UNDER the title "Prehistoric Indian Village, New Mexico" reference was made in NATURE of September 23, p. 542, to the work of an expedition under the leadership of Dr. Paul S. Martin. We are informed that Dr. Martin is, and has been for several years, chief curator of the Department of Anthropology of the Field Museum of Natural History, Chicago, and the expedition referred to is the ninth that Dr. Martin has undertaken for the Museum. The statement that the expedition was sent out by the American Museum of Natural History of New York is incorrect.

LETTERS TO THE EDITORS

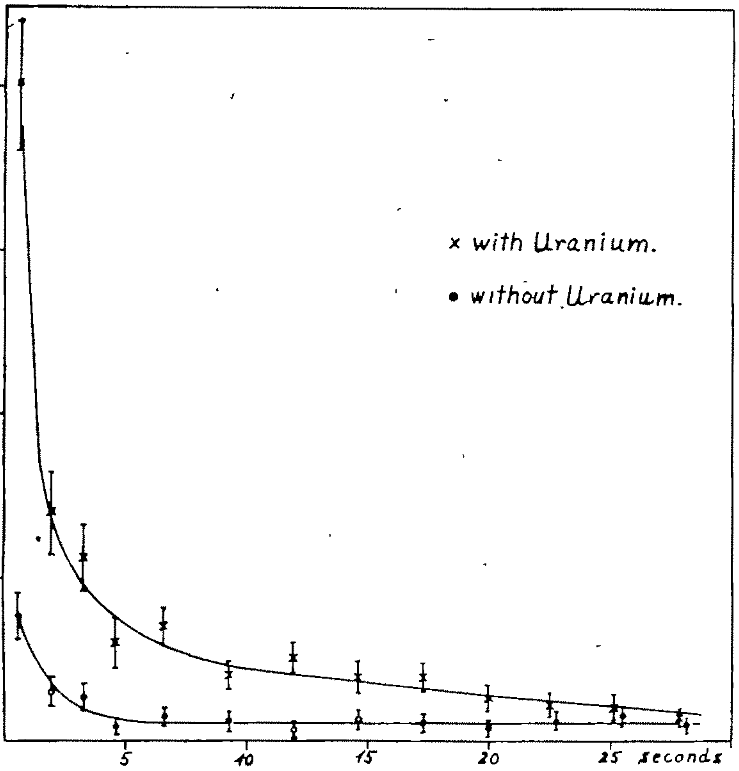
The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 836.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Delayed Neutron Emission accompanying Uranium Fission

As first observed by Roberts, Meyer and Wang[1], the fission of uranium is followed by an emission of neutrons with a delay of about 12 seconds. As this period corresponds roughly to a β-ray period of about 10 seconds previously found by Meitner, Hahn and Strassmann[2] in their study of the uranium neutron reactions, it was suggested that the neutron emission is directly connected with the process of β-ray emission. Further experiments[3] confirmed this conclusion and led to an estimate for the cross-section for the production of such delayed neutrons of about 4×10^{-26} cm.[3]. The subsequent work of Booth, Dunning and Slack[4] established the existence of an additional period of about 45 seconds, which could also be brought into connexion with a known β-ray period of the uranium products.



The theoretical analysis of the problem by Bohr and Wheeler[5] points to a simple explanation of these results, and suggests also the possibility of still shorter periods both for β-ray and neutron emission. The existence of two additional β-ray periods of 0·3–0·9 and 3–4 seconds was, in fact, established the recent experiments of Barschall, Harris, Kann and Turner[6]. Experiments were then initiated this laboratory to ascertain whether the correspondi neutron periods occur.

In these experiments, 1½ kg of uranium nitrate surrounded paraffin were exposed to the ne trons from a lithium target bo barded by a deuteron beam 900 kv. and 20 microamper The beam was intermittently off by means of a switch in t power supply to the ion sour The neutrons emitted from t uranium were detected in a borc lined ionization chamber plac immediately under the urani container. The pulses from t ionization chamber were amplifi and recorded on an oscillogra operated synchronously with t ion source.

The accompanying figure giv the result of measurements ma after irradiation periods of seconds and interspersed with co trol measurements without ura ium. The 12-second period p viously reported is clearly show In addition, a decay of the neutr emission of shorter period is a parent with a starting intensi somewhat larger than that giv for the 12-second period. Besic showing the presence of a period about 3 seconds, the figure giv also some indication of a peri between 0·1 sec. and 0·3 sec. However, the defin establishment of such a short period is render difficult by the large background shown in the cur taken without uranium. This background is due electrical disturbances from the high-tension equ ment occurring when the ion source is turned off, a it is hoped that by more careful shielding of t amplifier the effect may be reduced in continu experiments.

Recently, Gibbs and Thomson[7] have report similar investigations with an intermittent i source of special construction allowing the study periods as short as 10^{-3} sec. Because of the l neutron intensities available to them, they could n detect any definite neutron period in the range fr 10^{-3} to 10 seconds, and were only able to conclu that the total cross-section for the production of su periods was at any rate not much larger than 10^{-25} cm suming that the cross-section for the 12-second riod[3] is 4 × 10^{-24} cm.[2], the total cross-section ven by our experiments for periods down to about 1 sec. is less than 2 × 10^{-24} cm.[2]. The experiments Gibbs and Thomson are, therefore, in no way in sagreement with ours, and indicate further that ere are no intense periods between 10^{-3} sec. and $^{-1}$ sec., in accordance with theoretical expectations[5], nsidering the lack of very hard β-rays accompanying e fission process[6].

We are obliged to Prof. Niels Bohr for suggesting e problem, and to Prof. T. Bjerge and Dr. O. R. isch for valuable advice in the setting up of the periments.

sonance Capture of Slow Neutrons and Emission of Gamma-Rays

The determination of neutron resonance energies nuclei which are made radioactive after neutron pture is possible by utilizing their activities, and veral such cases are known; for example, silver, odium, iodine, indium, gold, etc. But in the cases nuclei which are not made radioactive, it is much re difficult to discover the existence of resonance utron groups and to determine their energies. A. Bethe[1] has suggested several methods for such ses, but no noteworthy results have been obtained cept that of A. E. Dowing and C. D. Ellis[2]. S. Nishikawa and others[3] have pointed out that it possible to detect the resonance groups by an alysis of the activity curve as a function of thickss of paraffin layer interposed between a radon plus beryllium source and a detector which became radioactive by neutron capture. A similar experiment was carried out by Y. Sugiura and O. Minagawa[4] with a D + D neutron source.

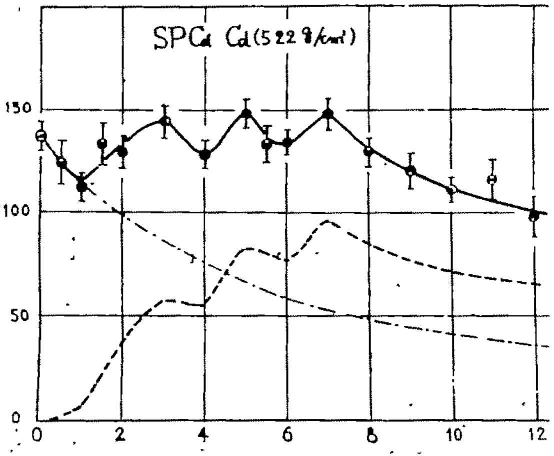

Fig. 1.

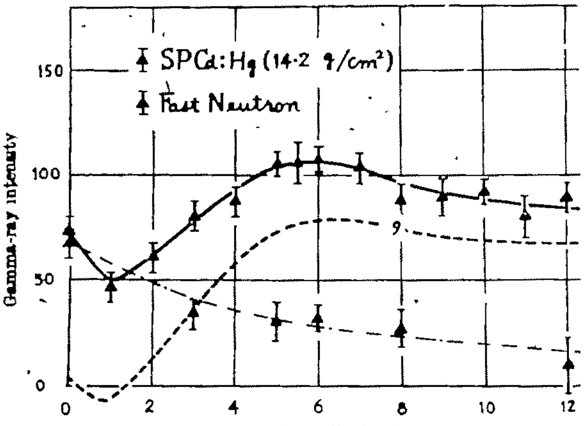

Fig. 2.

In the case of non-active substances, however, it may be possible to utilize the gamma-rays emitted in the capture process itself. Following this idea, the gamma-ray intensity was measured for iron, cadmium, mercury and bismuth by a Geiger-Müller counter as a function of the thickness of paraffin layer interposed between a D + D neutron source and a detector. When thermal neutrons were interrupted by a cadmium filter interposed in an appropriate position, the gamma-ray intensity curve should have one maximum at a certain thickness of paraffin if the detector had one resonance level. The position of the maximum would depend on the energy of the resonance level.

Gamma-ray intensity curves obtained for cadmium and mercury are shown in Figs. 1 and 2. As gamma-rays are excited also by fast neutrons, it is necessary to subtract this part of the gamma-rays in order to get the effect of slow neutrons only. The number of fast neutrons which can excite gamma-rays is calculated as a function of paraffin thickness on the assumption that a fast neutron can excite gamma-rays only when its energy is greater than 1·9 Mev., an average of the values of maximum quantum energies of fast neutron gamma-rays obtained by H. Aoki[5]. The result of the calculations is shown in Fig. 1 or 2 (broken line). An experiment was performed to test this calculated result by absorbing slow neutrons by a thick layer of boric oxide (0·78 gm./cm.[2] of boron). The result is shown in Fig. 2, after being corrected for the residual effect of slow neutrons.

From analyses of gamma-ray intensity curves and measurements of energy by the boron absorption method, it can be shown that mercury has a clear resonance group of about 10 ev. in energy, cadmium has several groups of energies from several tens to a few electron volts, and the mean energy of these groups, plus the residual part of the first resonance group (E_r = 0·17 ev.) not absorbed by the cadmium filter, is about 2 ev. Bismuth has a resonance group giving a flat maximum of gamma-ray intensity at about 5–7 cm. thickness of paraffin. Iron has no distinct groups.

For thermal neutrons the maximum of gamma-ray intensity was found at 9 cm.

In conclusion, I wish to express my thanks to Mr. Masamichi Tanaka for encouragement throughout this work, and also to Mr. O. Minagawa for discussions. A detailed report will be published shortly by the Physico-Mathematical Society of Japan.

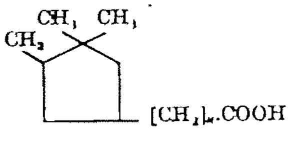
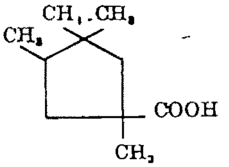
A Solid Naphthenic Acid from Iranian Petroleum

The importance of the study of the naturally occurring acidic constituents of petroleum, both in the recognition of the individual hydrocarbons from which they are derived and in their application in the domains of medicine and technology, has been stressed by v. Braun[1]. Although, however, the naphthenic acids have been recognized for more than sixty years, owing to the fact that many isomers are possible, it is only comparatively recently that pure individuals have been isolated, many, which had previously been reported as pure, having been proved to be mixtures. v. Braun, Mannes and Reuter[2] are usually considered to have been the first to isolate a homogeneous naphthenic acid by a rather indirect route. Degradation of mixtures, of acids of the general formula $C_{10}H_{18}O_2$ from different sources gave the same 3.3.4–trimethyl*cyclo*pentanone, which was reconverted to 3.3.4–trimethyl*cyclo*pentylacetic acid. All the higher acids $C_n H_{2n-2} O_2$, out of which the above ketone could be obtained by degrading one or more times, therefore correspond to the formula (I) (v. Braun *et alia*, *loc. cit.*)



(I)



(II)

Recently, Nenitzescu, Isacescu and Volrap[3] have isolated and identified *cyclo*pentane, *cyclo*pentyl-acetic and 3–methyl*cyclo*pentylacetic acids from a Rumanian source.

During an investigation of the caustic washing liquors after use in removing traces of acid from a kerosene sulphur dioxide extract derived from Iranian petroleum, the presence of naphthenic acids in an oil from this source was proved for the first time. A subsequent investigation showed that naphthenic acids occurred in the kerosene sulphur dioxide extract to the extent of approximately 0·025 per cent by weight, of which about 10 per cent was removed by the light caustic washing. The spent caustic washing liquors after washing 2,000 gallons of kerosene sulphur dioxide extract were neutralized and the precipitated oil worked up in the usual manner into acidic, phenolic, mercaptan and hydrocarbon fractions. The acidic material was esterified three times by means of methyl alcohol and hydrochloric acid, whereby all the primary and secondary acids could be remov
from the difficultly esterifiable tertiary acids.

The residual tertiary acids on standing for a fe
days yielded a white crystalline solid which aft
many crystallizations from low boiling petrol h
constant m.p. 82° (found, C, 70·90; H, 10·7
$C_{10}H_{18}O_2$ requires C, 70·52; H, 10·66 per cen
molecular weight by titration: 173; $C_{10}H_{18}$
requires 170). The anilide crystallized in colourle
flat needles from aqueous methyl alcohol, m.p. 186–
(found C, 78·32; H, 9·38; N, 5·73; $C_{16}H_{23}O$
requires C, 78·30; H, 9·45; N, 5·71 per cent). I
fractional crystallization of the mother liquors
total yield of 3·3 per cent of the acid was obtain
on the original acid mixture from the caustic washi
liquors. The acid proved to be saturated, and mu
therefore contain a closed carbon ring.

In line with the results of Nenitzescu *et alia* (*l*
cit.) and of v. Braun *et alia* (*loc. cit.*), it is suggest
that the above acid possesses a polymethyl*cyclo*pent
structure, possibly (II). Further information will
published elsewhere when larger amounts are ava
able for study.

I wish to record my thanks to the chairman of t
Anglo-Iranian Oil Company, Limited, for permissi
to publish these results.

Since this work was completed, a publication
Hancock and Lochte has appeared[4] describing the i
lation of a solid tertiary naphthenic acid, m.p. 19
194·5°, from a California straight-run gasoli
distillate which they have shown to be identical w
camphonanic acid (1.2.2–trimethyl-*cyclo*pentanec
boxylic acid).

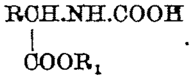
Carbamates of α-Amino-Acid Esters and their Po condensation

On passing a stream of carbon dioxide throu
strongly cooled, pure α-amino acid esters or th
solutions (for example, in ether) with certain p
cautions, new crystalline products have been obtain
After careful purification the products give analyti
data which correspond to the formulæ of carbama
of the α-amino acid esters of the general form



$$\begin{array}{l}\mathrm{RCH.NH.COOH}\\ \quad\ \ |\\ \quad \mathrm{COOR_1}\end{array}$$

A number of them, for example, glycine carbam
ethyl ester, alanine carbamate ethyl ester, phen
glycine carbamate ethyl ester, have now been p
pared and analysed. The new compounds sh
various degrees of stability at low temperature.
room temperature they decompose more or l
rapidly, giving off carbon dioxide; the dissociat
is considerably increased on warming *in vacuo*.

Besides being of interest in itself, this class
amino-acid derivatives is of value in carrying
poly-condensations of amino-acids.

As has been shown in a previous communicati
amino-acid esters exhibit a tendency to condense, fo
ing, *inter alia*, polypeptide esters of varying ch
length. This tendency of the amino-acid esters see
to be enhanced by the introduction into their mole

the readily cleavable COO-group, removal of which bound to leave an NH$_2$-group *in statu nascendi* hind.

According to Curtius and to E. Fischer, the glycine yl ester on standing for several weeks gives as hest condensation product the biuret base, the raglycine ethyl ester. Under similar conditions, cine ethyl ester carbamate yields a mixture which ording to the analytical data seems to contain, *inter ia*, glycine peptide esters of considerably higher chain gth.

From alanine carbamate ethyl ester a product was tained which gave the biuret reaction. From this ixture, tetra-alanine ethyl ester was isolated.

Systematic experiments on the synthesis and operties of carbamates of the various representa-ve amino-acid and peptide esters and on their ndensation are in progress.

Max Frankel.

An Easily Arranged Periodic Action

Lecturers wishing to demonstrate the existence periodic phenomena may be interested in a scription of a periodic action that can be set up in few minutes.

The surface of a sheet of lead was amalgamated ith mercury and while it still possessed some fluidity drop of concentrated nitric acid was placed on it. reading started immediately, but ceased when the ameter of the area of wetting reached about 1·5 cm. fter an induction period of about a minute, during hich time there was no apparent action, a considerble evolution of gas occurred at the mercury surface, ut this continued only for a fraction of a second. eriods of apparent quiescence and gaseous evolution hen followed regularly, at intervals of about a cond. Pulsations continued for some minutes, until ad nitrate crystallized from the liquid phase.

The presence of mercurous nitrate in the nitric acid cilitated the initial amalgamation, but the surface ad to be dried before the acid was placed upon it, therwise spreading proceeded too far. Some factor ot yet identified caused variations in the period of ne cycle. With some specimens of lead of doubtful urity it was necessary to dilute the acid with up to ne third of its own volume of water in order to get ulsations of sufficiently long period to be readily bserved.

The reaction seems to be that lead (not mercury) issolves, with liberation of nitrogen peroxide or ther oxides of nitrogen.

ffect of Irradiating the Tubercle Bacillus with Radon

Immunity against the tubercle bacillus seems to be due to the presence of living bacteria in the body; t is then of importance to obtain non-virulent but ving bacteria. The virulence of pathogenic bacteria is enerally attributed to their power of multiplication. In actual fact, this is the result of two independent variables:

(1) The toxicity factor T or the mean toxicity potential of the bacteria. This potential for a stable strain is first of all dependent on the host and secondly on the mode of innoculation (excipient, medium, rhythm). Specificity might be connected to this factor.

(2) The numerical factor N_t, or the number of bacteria *in vivo* at a given moment of the infection. Schematically, $V = T.N_t$, N_t being itself a function of N_0, the number of bacteria injected and of their time of generation *in vivo*.

The virulence of a bacterium may then be influenced by acting on either of these factors or on both of them. Calmette acted on the toxicity factor, obtaining B.C.G.; we preferred to act on the numerical factor, inhibiting proliferation without modifying, so far as possible, the other cellular functions. Among the physico-chemical agents available, we selected the ionising radiations, as most suitable for our purpose.

We have irradiated aqueous suspensions of human tubercle bacillus (1 mgm./c.c.) using the whole of the radiation of radon dissolved in the culture. The technique we have elaborated enables us to obtain reproducible results depending exclusively on the doses employed, given in microcurie destroyed per cubic centimetre of the bacterial emulsion. (One microcurie disintegrated (1 μc.) corresponds to the emission of $5 \cdot 5 \times 10^{10}$ α-particles, $3 \cdot 6 \times 10^{10}$ β-particles and to the formation of 10^{16} pairs of ions or 5×10^{6} r. An area of $0 \cdot 5\,\mu^2$ (mean cross-section of a B.K.) is traversed at this dosage by 1·2 α-particle and 33 β-particles. The γ-radiations are negligible.) The following results are observed.

(1) More than 9 μc. radon disintegrated. Proliferation on Löwenstein medium is regularly suppressed. The form of the curve showing the relation between the number of surviving bacteria and the dose employed could not be traced with precision owing to the uncertainty of counts on this medium. If, as it seems, this curve is of exponential form, the effect of 1·5 μc. corresponds to a dilution of 1/10 of the surviving bacteria.

(2) Cultures thus irradiated remain virulent for the guinea pig up to 14 μc. Above 15 μc., guinea pigs which received under the skin of the thigh 5 mgm. of irradiated B.K. remain unaffected.

(3) *Persistence of respiration of irradiated non-virulent B.K.* It was of importance to assure oneself that the bacteria the virulence and proliferation of which were destroyed, still possess vital properties. This has been done in the following way.

An emulsion of living B.K. was divided into three parts: one was irradiated at 20 μc., the second left untouched and the third killed at 120° C. These suspensions, to each of which 5 per cent of buffered glycerine (*p*H 6·8) was added, were placed in the vessels of a Warburg respirometer. The experiment was conducted under sterile conditions, each vessel being separated from its manometer by a piece of sterilized cotton (Rapkine). It has been established that the irradiated bacteria still respire for about five days. The consumption of oxygen during this period is about 20 per cent that of an equal weight of living bacteria. Thus there remains at least 20 per cent of living bacteria in the irradiated suspension.

While we cannot report fully here on the anti-tuberculosis immunity obtained with irradiated bacteria, we may nevertheless enumerate the following facts.

(1) Guinea pigs vaccinated with such bacteria and tested with 1/50 mgm. of virulent B.K. show a survival (250 ± 40 days) double that of controls (133 ± 30 days), the difference being statistically significant.

(2) A regular decrease of temperature and an improvement of the lesions have been observed in most of the cases of tuberculosis, bony, ganglionar, kidney and pulmonary, under treatment (60 cases). The complete harmlessness of the vaccine has been established even in very serious cases; the radio-vaccine never caused recrudescence.

Thus the action of ionizing radiations enables us to obtain living human tubercle bacillus which are non-virulent; this would seem to be of particular interest to immunologists.

Necessity of Magnesium in the Pyruvate Oxidation System of Brain*

THE necessity of Mg^{++} in enzymic reactions involving transfer of phosphate groups through the adenylic acid system is well known. More recently, Mn^{++} has also been shown to be active in reactions of this type[1]. Further, Auhagen[2] and later Lohmann and Schuster[3] showed that the decarboxylation of pyruvic acid by yeast requires Mg^{++} (or Mn^{++}). This made it likely that these ions are also necessary for the oxidative breakdown of pyruvic acid in animal tissues, the more so as this breakdown is related with reactions involving the adenylic acid system[4].

Stimulation by Mg^{++} of the oxidative decarboxylation of pyruvate by washed muscle preparations was reported by Annau and Erdős[5]. Addition of Mg^{++} has little or no effect on the oxidation of pyruvate by dispersions from pigeon brain[4] after short dialysis periods (2–3 hours), but the effect is more marked if the dialysis is extended for periods of 8 hours. A clearer demonstration has, however, been obtained by adding to the enzyme an excess of sodium pyrophosphate (0·0067 *M.*) to precipitate magnesium. Pyrophosphate is then removed to the extent of 90 per cent by 8 hours dialysis, when its concentration is of the order of 0·0007 *M.* and is, by itself, without effect on the respiration of the brain preparations. The preparations which have, however, been treated as described above give with pyruvate nearly one third of the oxygen uptake which can be obtained by adding Mg^{++}. These facts are illustrated in the table below. Samples contained 1·5 ml. enzyme (dialysed 8 hours), brought to a volume of 2 ml. with additions including phosphate buffer *p*H 7·3 (0·05 *M.*), fumarate (0·005 *M.*), adenylic acid (0·0007 *M.*), and cozymase (0·00007 *M.*).

Treatment	Pyruvate	Mg^{++} (as $MgCl_2$)	Mn^{++} (as $MnCl_2$)	μL. oxygen uptake in 30 min. (air, 38°)
No pyrophosphate	—	—	—	2
	—	100 γ	—	61
	2 mgm	—	—	280
	2 ,,	100 γ	—	432
Pyrophosphate treated	2 ,,	—	—	175
	2 ,,	100 γ	—	400
	2 ,,	150 γ	—	455
	2 ,,	—	100 γ	345

Mg^{++} (or Mn^{++}) is therefore a component of t pyruvate oxidation system.

I am indebted to the Nuffield trustees for gran in aid of this work.

Sex Difference in the Response of the Pigeon Crop-Gland to Prolactin

IT has generally been thought[1] that there is detectable sex difference in the response of the pigeo crop-gland to prolactin. Folley and White[2], howeve were able to demonstrate a significantly great response in males than in females, a finding whic has since been confirmed by Bates and Riddle[3] f subcutaneous but not for intramuscular injections.

Preliminary examination of more extensive resul which have accumulated in this laboratory in t course of further experiments on the inhibition oestrogens of the prolactin response[4] appeared at fir sight to indicate no sex difference in response. Sinc however, re-examination of the original records Folley and White revealed that their groups con sisted almost entirely of immature birds, a furth analysis of the above-mentioned data, in which t birds were classified as mature and immature on t basis of gonad size at autopsy, was undertaken Details of the experimental technique are given else where[4], the birds referred to below comprising t prolactin and oil-injected controls together with group of birds used for constructing a dose-respons curve.

The following results relate to two groups of bir receiving the same daily dose of prolactin but differen doses of sesame oil (these were also combined to mak a third group on the reasonable assumption that t sesame oil injections had no effect on the prolacti response) and a fourth group receiving a lower do of prolactin. For groups of 'mature' birds the mea male crop weights exceeded those of females by 0·1 0·06, 0·08 and 0·17 gm. per 100 gm. body weig respectively, the corresponding values of *P* (Fisher '*t*' test[5]) being 0·3–0·4, 0·5–0·6, 0·3 and 0·2–0· For 'immature' birds the mean crop weights of mal were 0·30, 0·31, 0·36 and 0·11 gm. per 100 g body weight greater than those of females. Here th values of *P* were 0·14, 0·076, 0·01–0·02 and 0·1–0·

It will be seen that for 'mature' birds the differenc between the male and female crop weights we small and apparently not significant. On the oth hand, in 'immature' birds receiving the higher do of prolactin the differences were much larger and th significance levels much higher. It therefore appea that this sex difference in response to prolactin most marked in pigeons with undeveloped gonad

Histological Effects of Diabetogenic Anterior Pituitary Extracts

AT the request of Prof. C. H. Best, in whose epartment studies were being made on other aspects f the diabetogenic effects of pituitary extracts, we ade a histological study of the tissues of dogs hich were receiving daily injections of an anterior be extract. The clinical evidences of diabetes as ell as the results of insulin assays on the pancreases f these animals is reported elsewhere (Best, Campbell nd Haist[1]). For our work, pancreas tissue was btained under anaesthesia, other tissues shortly fter death. Tissues were fixed in Zenker-formol and ouin's solution and sectioned in paraffin. Three icron pancreas sections were stained by the Mallory-zan technique, Bowie's stain and other methods iving islet cell differentiation. Hæmatoxylin and osin sections were prepared from all the organs. he histological findings are summarized in the ollowing table.

Number of days injected	2	3 and 4	7	11*
eta cell granules	Slight deplet.	Moderate deplet.	Moderate deplet.	Marked deplet.
lpha cells	No change	No change	No change	No change
itoses in islets	One seen	A few	Several	None seen

itoses liver	Not seen	Not seen	Not seen	Many
itoses kidney	Not seen	Not seen	Many in Loop of Henle	None seen

* Two dogs were injected for eleven days. The findings of one were milar to those presented for dogs injected seven days, the findings of e other are presented in this column.

NOTE. (1) The first seven items are concerned with the pancreas;) three- and four-day dogs are grouped together to save space, but e findings in them although similar are not identical; (3) one dog jected only once is not included in the table; it showed no change xcept a heightening of the thyroid epithelium; (4) each dog was acrificed twenty-four hours after its last injection.

Although islet degeneration is pronounced in ermanent pituitary induced diabetes (Richardson nd Young[2], Campbell and Best[3]), our findings uggest that temporary diabetes has a much more omplicated histological basis. In the early stages f the condition we did not find a great deal of islet egeneration; moreover, there were profound changes n many other organs related to carbohydrate etabolism.

The remarkable amount of cell division in the hyroid, parathyroid and adrenal cortex indicates hat the extract contained these glands' respective ropic principles. Cell division in the ducts, acini nd islets of the pancreas likewise indicates a pancreatropic principle in the extract. Anselmino, Ierold and Hoffmann[4] first postulated such an xtract and Richardson and Young[5] have shown hat injections of a crude saline extract of anterior obe causes both the islet and total pancreas tissue f the rat to increase in amount. Our findings confirm the view that there is such a principle and ndicate that its action is by no means limited to islets as is so often assumed, but affects acini as well. This is only to be expected as the pancreas is both an exocrine and an endocrine gland with both elements evolving from the same stem cell. Hence a pancreatropic principle could be expected to produce the effects we observed.

Allen[6], from studies on partially depancreatectomized animals, postulated that beta cells, subjected to excessive functional strain, suffered hydropic degeneration. It therefore does not seem unreasonable to attribute the extensive hydropic degeneration we observed at eleven days to overstimulation by the pancreatropic principle in the extract. Thus we think there is no justification at present for postulating any pituitary principle which is primarily degenerative with regard to islet tissue. The paradox of a diabetogenic effect being produced by an extract containing a pancreatropic principle might be explained (1) by the extract containing many tropic principles which early in the course of the injections affect carbohydrate metabolism by acting on organs other than the pancreas, for example, thyroid and adrenal cortex, and so obscure the effect of the pancreatropic principle, and (2) by the probability that beta cells do not respond to tropic stimulation with such sustained vigour as most cells, but tend to become exhausted and even permanently injured as the injections continue.

Occurrence of Wax-like Substances in Peaty Fireclay

ASSOCIATED with the usual type of fireclay in the Ecca Series of the Karroo System in the Witwatersrand area are certain chocolate-coloured, very plastic and fine-grained refractory clays. The colouring matter is organic and mainly colloidal. The clays are difficult to disperse, unless the organic matter is totally destroyed. Owing to the fine state of division of the organic phases, mechanical separation from the inorganic material is impossible. Extraction tests in a Soxhlet apparatus with solvents specified gave the results in the table below.

In general, the extracted substances are waxy, oxidizing rapidly on heating to 110° C. to a dark brown translucent material. The green colouring matter in the alcohol extraction is not due to the presence of vanadium, a fairly commonly occurring element in clays.

Solvent	Extraction time (hr.)	Percentage extracted material	Character of extracted material
Acetone	14	0 12–0·20	Brownish translucent wax
Acetone	4	0 03–0 06	Brownish translucent wax
Ethyl alcohol	28	0·12	Light green transparent wax
Pyridene	14	0·72	Dark brown waxy material with tarry substances

Reilly and others[1] record their results on the extraction of waxy materials from peats, using an azeotropic petroleum mixture. Their yields were much greater, and the peats certainly contain much more organic matter than the fireclays.

It is noteworthy that the fireclays after extraction show no colour change, and all attempts to extract the pigmenting material have failed. Micro-incineration tests show that the organic matter burns off readily at 500–600° C. and leaves a dirty white residue. It chars far below this range. Owing to the rapid oxidation and small amounts of material, accurate melting point and other physical determinations were impossible, but the substance melts at about 90–100° C.

A New Record of *Phoronis hippocrepia* Wright

I found many colonies of *Phoronis hippocrepia* on limestone boulders uncovered at low water of the biggest spring tides in July and August 1939. This was on the collecting ground known in our laboratory as Black Rocks, at the eastern end of the Menai Straits. Most of the individuals had embryos attached to the lophophore.

This species must be widely distributed around th west coast of Great Britain and the English Channel for it has been recorded from the Clyde[1], Tenby[2] Ilfracombe[3], Falmouth[4], Plymouth[4] and Sheerness[4] and also from several places on the French coast On the other hand, anyone requiring fresh specimen might have difficulty in obtaining them. Th Plymouth Fauna List does not record it as occurrin on the shore although, according to Cori[5], this is th usual habitat. Mr. D. P. Wilson tells me that it i occasionally dredged at Plymouth to-day, sometime in considerable quantities ; but that it is not alway easy to obtain. As for its occurrence elsewhere w have only the old records. Since the other Britis forms, *P. ovalis* Wright and a form resemblin *P. psammophila* Cori, are probably rarer still, th presence of this species near Bangor appeared worth of note, as it is desirable that material of so interestin an animal as Phoronis should be readily availabl for study.

Points from Foregoing Letters

K. J. Bostrem, J. Koch and T. Lauritsen have found short periods for the delayed neutron emission accompanying uranium fission in addition to the two previously known periods of 12 seconds and 45 seconds. The results can be related with the measurements on short β-ray periods from uranium fission, and can be explained by theoretical considerations recently published by Bohr and Wheeler.

An attempt has been made by I. Nonaka to determine the neutron resonance energies of nuclei which are not made radioactive by neutron capture, utilizing the gamma-rays emitted in the capture process itself. The intensity of gamma-rays produced by slow neutrons plotted against thickness of paraffin interposed between source of neutrons and the detector shows maxima representing resonance levels in the cases of mercury, cadmium and iron.

T. Kennedy reports the isolation of a solid naphthenic acid from an Iranian petroleum fraction. The acid has the formula $C_{16}H_{18}O_2$, is saturated, contains a tertiary carboxylic acid group and one closed carbon ring. A *cyclo*pentane structure is tentatively suggested.

It has been found by M. Frankel, O. Neufeld and E. Katchalski that on passing carbon dioxide through pure α-amino-acid esters or their solutions carbamates of the α-amino esters of the general formula

$$\begin{array}{l}\mathrm{RCH.NH.COOH}\\ \ \ |\\ \mathrm{COOR_1}\end{array}$$

are formed. These compounds are also valuable in carrying out poly-condensations of α-amino-acids. They form polypeptide esters of varying chain-length.

P. Bonet-Maury and H. R. Olivier describe method which should be of value to immunologist whereby non-virulent human tubercle bacilli ar produced. The non-virulent bacilli are obtained b irradiating aqueous suspensions of human tubercl bacilli, using the whole of the radiation of rado dissolved in the culture.

S. Ochoa reports that the pyruvate oxidatio system of brain requires the presence of magnesium (or manganese) ions.

A. W. Ham and R. E. Haist have made a histo logical study of the tissues of dogs injected dail with a diabetogenic anterior pituitary extract. complex histological basis for the early phases o temporary diabetes was indicated by a lack of sever islet damage and profound changes in many othe organs related to carbohydrate metabolism. pancreatropic principle in the extract was indicate by mitotic figures in islets, ducts and acini. Th hydropic degeneration which develops later in th course of injections may possibly be explained b the continued action of the pancreatropic principl on beta cells.

The occurrence of wax-like substances from peat fireclays of the Karroo System in South Africa i described by V. L. Bosazza. He was unable to extrac the pigmenting material.

E. W. Knight Jones records the occurrence o *Phoronis hippocrepia* Wright in North Wales, pointin out the paucity of recent records of this form i Great Britain.

RESEARCH ITEMS

Further Concepts of Serbian Gypsies relating to Disease

Bibi, who brings disease to Gadže children, but protects gypsy children from every illness, says Alexander Petrovič (*J. Gypsy Lore Soc.*, Ser. 3, 18, ; 1939), among the gypsies of Golubinci is regarded as a hen. When she flies her chickens fly after her; and they are devils, witches, fever, cholera, diphtheria, and every kind of disease. Some believe that Bibi is in the whirlwind. They are afraid of the whirlwind, and believe that when it gets hold of a man he loses the use of an arm or a leg, or his speech. Bibi is found in dust: we breathe or swallow dust, and disease with it. Illness is caught at the new moon, and waxes and wanes with the moon. Other gypsies believe that cholera is brought to the village by a woman "dressed in black", who carries disease nly to those houses which are unclean. They onclude that a man is saved from cholera who keeps his house clean. The Golubinci gypsies, on the ontrary, with a similar belief as to the origin of the disease, have come to the opposite conclusion. Because Bibi does not like smoke, dust, dirty napkins, dirty clothes and greasy pillow-cases, and these hings stifle her, she will flee. In a house where verything is clean, she enters, touches each inmate, and they die. In the spring when colds, fevers, etc., begin to be prevalent, small dolls are dressed in red, one of which thrown into the well drowns Bibi, the other suspended from a high pole, is Bibi's son, the devil who drives her away. The Golubinci gypsies believe hat every illness comes from fever. This may account for the belief that Bibi is a hen. A man suffering rom malaria trembles violently, just as a hen does, when she beats her wings as if shaking off something. Thus it is not the sick man who shivers and trembles, but the disease itself, the hen that is in him.

North American Indian Music

Miss Frances Densmore, in continuation of her studies of the music of the indigenous peoples of North America, has published songs collected among the Nootka and Quileute of Neah Bay, Washington, on the Strait of Juan de Fuca, near Cape Flattery *Bureau Amer. Ethnol. Bull.*, 124; 1939). These songs of the sea' are here compared with those previously collected among Indians of the prairie, woodland, high plateau and desert. The people are hunters of the whale; they use wooden canoes, and n pursuit of their prey often put far out to sea. Though not of great stature, their physical strength s considerable. They were warriors who cut off the heads of their enemies and displayed them on poles before their village. The potlach was practised with lavish generosity. Among their principal foods were the oil and meat of the whale, the flesh of sea-fowl and other birds, potatoes, fern roots, grasses and water plants and various berries. Climatic conditions are unfavourable to the growth of grain. Their songs, of which 44 per cent have a major tonality as against 38 per cent in Pawnee and 71 per cent in the Ute repertoire, while they show the smallest percentage beginning on the octave above the keynote, are characterized by a small compass; 70 per cent have a compass of six tones or less, compared with 15 per cent in the songs previously analysed. The songs recorded are connected with every department of life and individual and communal activity. They are both ritual or magical in significance as well as purely recreational. One of the most interesting from the cultural aspect is the group associated with whaling in which the skilled whaler was assisted by a strong tumanos (guiding, protecting spirit) acquired as the whaler's first task in the course of prolonged fasting and prayer.

Inheritance of Cyanogenesis

R. D. Williams (*J. Genetics*, 38, 356–366; 1939) shows that some plants of wild white clover (*Trifolium repens*) contain a cyano-glucoside. There is a large variation in the HCN content of the different plants. 1,495 plants resulting from a cross between individuals giving a positive and a negative reaction to the picrate paper test gave positive reactions while 2,473 plants from crosses between acyanogenetic plants gave negative reactions. Further crosses show that the presence of a cyano-glucoside is governed by an almost completely dominant gene *Ac*. Variation in the HCN content between individuals is probably due to modifying factors.

Genetical Analysis of Abnormal Chromosomes

The value of genetics in the analysis of cytological abnormalities is ably demonstrated by B. McClintock (*Proc. Nat. Acad. Sci.*, 25, 405–415; 1939). An abnormal chromosome 9 of *Zea Mays* formed as the result of irradiation with X-rays possessed two centromeres. Therefore the chromosome will break at anaphase I. In order to discover the subsequent history of this chromosome, the behaviour of the genes *Yg C Sh* and *Wx* was studied in plants heterozygous for the abnormal chromosome. It was shown that in embryo and plant tissue the broken ends do not rejoin, but in the embryo sac and endosperm there is a cycle of breakage—fusion of broken ends—bridge formation—breakage at succeeding cell divisions. This phenomena can be followed by the appearance and behaviour of hybrid fruits, which are sometimes variegated as the result of loss of a gene through breakage and refusion of the chromosome.

Position Effect in Œnothera

D. G. Catcheside (*J. Genetics*, 38, 345–352; 1939) has studied X-ray derivatives of the structural homozygote of *Œnothera blandina*. One derivative, *blandina-a* when crossed with *blandina* forms a ring of four chromosomes involving the chromosome 3·4 on which the gene *Ps* is known to be placed. *Ps* normally gives flower buds broadly striped with red separated by narrow green bands. In the heterozygote *blandina-a-blandina*, however, there are narrow ill-defined bands of red. By crossing the F_1 *Ps-blandina-a.Pr blandina* with *Ps blandina*, one *PsPs-blandina* plant in 96 plants occurred. This probably arose as the result of crossing over in the F_1 plant. The author therefore concludes that the activity of the *Ps* gene in *blandina-a* is reduced by its relocation in position relative to the material different from normal blandina.

Genetics of the Garden Nasturtium

EILEEN SUTTON (*J. Genetics*, 38, 161–176; 1939) reports the results of further genetical experiments on the garden nasturtium (*Tropæolum*). The gene *n* reduces the size of plant and of leaves and prevents the anther from dehiscing. The gene *m* gives a sheen to the petals, increases the *p*H value and shortens the flowering season. The effect of *m* on flower colour is to reduce scarlet to biscuit colour, red to mauve or brown, and pink to mauve. The factor *t* partially inhibits anthocyanin production. A gene *g* adversely affects the viability of the pollen-grain and, being linked with *B*, accounts for abnormal ratios of *B*. The genes *B* and *R* are linked with a cross-over value of 0·125. The biochemistry and interaction of characters and chromosome constitution of *Tropæolum* are discussed.

Invertebrates from Manchoukuo

FIVE zoological reports based on material collected by the expedition maintained by the Japanese in Manchoukuo during June–October 1933 under the leadership of Prof. Shigeyasu Tokunaga, of Waseda University, Tokyo, have been published (Rep. 1st Sci. Exp. Manchoukuo. Tokyo: Waseda University). The only earthworm reported is the widespread ***Eisenia foetida***. Four trematodes are described, two of which, *Pneumonoeces jeholensis* and ***Harmostomum momiyami***, are new. The three leeches have all been recorded previously from Japan and China. The two major papers are those on mammals and molluscs: both of them have the text in Japanese and English and both are illustrated by good plates, coloured and plain. Tamezô Mori describes 21 species of mammals, of which three species and two subspecies are regarded as new. Only twelve were actually collected by the expedition; the rest came from the Pest Investigation Institute at Tang-liao. Only four species of molluscs were found, one of which, ***Viviparus*** (*Idiopoma*) ***chengtehensis***, is new. The account occupies 222 pages (137 Japanese and 85 English) and is illustrated by 22 plates. It contains a detailed account of the anatomy of the species, a good deal of information of general interest, and a suggested revision of the Viviparidæ.

Wax Emulsions for Deciduous Fruit

FRUITS are still living organisms when separated from the parent plant, and this fact is responsible for the main difficulties of storage. Citrus fruits have been preserved in good condition for longer periods than normal by the application of a thin coat of wax; indeed, 80–90 per cent of the crops in California and Florida are so treated. Waxing lengthens the effective period of storage apparently by lowering the rate of respiration, and research work on this subject in America is now being directed towards the use of the process on deciduous fruits. Robert M. Smock, of Cornell University, reviews the progress of these investigations in the ***American Fruit Grower*** of August. Research is also in progress in the Universities of California and Maryland in addition to Cornell, and the main problem appears to be to diminish the rate of respiration, and check the evaporation of water from the fruit without stimulating anærobic respiration, with its accompaniment of bad flavour. Bitter pit and storage scald are reduced by waxing, under certain conditions, and the aroma of certain varieties like McIntosh is conserved. Considerable possibilities are revealed the paper, but the exact conditions of treatment a not yet sufficiently standardized for general cor mercial application.

Helium-Neon Content of Sea Water

THE vertical distribution of oxygen in the deep parts of the ocean shows a minimum concentratic (which may be very pronounced) at depths of 20 1,000 metres. In parts of the Pacific there is virtual no oxygen, whilst in the Atlantic the minimum zo is seldom less than 30 per cent saturated and in tl far north and south there is sometimes no minimur Reported analyses of the helium-neon content of s water showed an apparent minimum of the helium neon mixture coinciding with the oxygen minimun N. W. Rakestraw, C. E. Herrick and W. D. Ur (*J. Amer. Chem. Soc.*, 61, 2806; 1939), by a repetitio of this work under more suitable and representati conditions, have shown that specimens of Atlant and Pacific water are practically saturated wi helium and neon at all depths investigated (from to 3,000 metres) with no evidence of a minimu concentration at any depth. There is hence relation to the depth of oxygen minimum. Th result is in general agreement with other ocean graphic evidence.

Magnetic Testing

RECENT developments of alloys for magnet ste which require very high magnetizing forces f magnetizing and testing have led to the productio of high-field permeameters, and R. L. Sanford an E. G. Bennett, of the Bureau of Standards, descril the one adopted at the Bureau, which seems capab of a high degree of accuracy (*J. Res. Bur. Stand* 23, No. 3; September 1939). It is a double-yol apparatus with the adjustable pole pieces place diametrically. The yoke is of laminated silicon stee The pole pieces are channelled, with filler piec fitting closely in the channels and capable of adjus ment so as to grip the specimen to be tested, or the specimen is very short it is made to butt again the pole pieces. The magnetizing coils are woun mainly on the pole pieces with auxiliary coils on th yokes. The induction is determined by reversal the magnetizing current and the magnetizing fiel by coils rotated suddenly through 180°, close t the surfaces of the specimen. Both may be dete mined at various points along the specimen.

Mechanical Force due to an Electron Stream

DR. P. SELÉNYI of the Tungsram Researc Laboratories, Ujpest, Hungary, has sent an accoun of a measurement of the mechanical force exerte on an electrode by a stream of electrons. The electron were accelerated from a filament to a gold-leaf anod suspended as a pendulum. The pressures observe were 5–20 per cent higher than calculated from th accepted value of e/m for electrons, and this differenc is ascribed to radiometer effects. The author considers that this mechanical pressure requires for it explanation a 'true' as distinct from an 'electro magnetic' mass, for he points out that when a singl electron approaches a metallic screen, the electrodynamic repulsion due to induced currents depend on the conductivity of the screen, which is contrar to experience; while with a steady electron beam conditions are stationary and no repulsion due t induced currents is to be expected.

THIRD INTERNATIONAL CANCER CONGRESS

By Prof. F. C. Wood, Institute of Cancer Research,
Columbia University

HE Third International Cancer Congress, held under the auspices of the International Union inst Cancer, met in Atlantic City, New Jersey, A., during September 11–15, 1939, under the sidency of Prof. Francis Carter Wood of Columbia iversity.

nfortunately the onset of war prevented many the European delegates from attending, and ateur Justin Godart, president of the International Union against Cancer, felt that he could not ve France. A few English delegates, among them William Cramer of the Imperial Cancer Research d of London, were able to remain. Considerable gations came from South America and Mexico, Prof. R. Kinosita represented the Japanese ernment. The total attendance was more than hundred, and approximately the same number papers were read.

special feature was a group of evening lectures ch presented general surveys of various aspects the cancer problem and were prepared with the pose of interesting not only the specialist but also entire audience. In these lectures the subject of etic susceptibility to tumour formation in mice surveyed by Dr. C. C. Little of Bar Harbor, ine. Dr. A. Lacassagne of Paris presented the tionship of hormones and mammary adenocinoma in the mouse, and, as he was unable to be sent, his paper was read by the chairman. The er of Profs. Kennaway and Cook, also read in ir absence, dealt with the chemical compounds as cinogenic agents, and Dr. William Cramer of the perial Cancer Research Fund spoke on some phases he etiology of human cancer. Another interesting ning lecture was that on "Cancer and the Public lth" by Surgeon-General Thomas Parran of the ited States Public Health Service. A scheme for organization of a cancer clinic, with the methods recording the facts concerning patients and the hanical sorting of the cards on which records are t so as to obtain the desired statistics within a rt period, was presented by Prof. Fred J. Hodges he University of Michigan. Recent advances in cer surgery were discussed by Dr. Frank H. ey of Boston; and Prof. James Ewing of New k, under the title of "Cancer, Present and Future", marized the main features of the Congress and icated the direction in which research might pro- d in the future. The evening lectures were exceed- y well attended not only by the members of the gress, but also by the local medical fraternity, desired to obtain the latest information on pro- s in the investigation and treatment of cancer.

apers were presented in the following Sections: physics; Surgery; Therapeutic Radiology; Stat- s and Education; Genetics; General Pathology; erimental Pathology; Diagnostic Roentgenology; a General Section for those titles that could be included elsewhere or were received too

The Section on Biophysics included studies on the relation between concentration of ionization and the biological effect; the comparative action of X-rays and neutrons; a comparison of biological and physical measurements of X-rays produced at voltages from 200 to 1,000 kv.; the action of radiation on protoplasm, and the effects of X-rays on different viruses and genes.

In the Section on General Pathology there was an interesting series of papers on the relation between treatment with œstrogenic compounds and the tissue changes produced. Two of the authors believe that the administration of these substances in physiological doses or even in fairly excessive amounts cannot be held responsible for the production of malignant tumours in man, thus differing from the results obtained on animals by Lacassagne, Strong, and others, in which a carcinogenic effect, though perhaps not rigidly proved, is strongly suggested. Important papers were read in this section on tumours of the central nervous system, including one on brain tumours induced in mice by methylcholanthrene. Another communication was that by Martland on the occurrence of cancer in persons who have received considerable quantities of radioactive substances either for therapeutic purposes or accidentally as in various industrial processes. Other papers dealt with tumours of the ovary, pancreas, and parathyroid.

The Section on Experimental Pathology had a very large number of papers and of such variety that every phase of cancer research was included, with a full discussion of the recent studies on leukæmia in animals and the correlations between this disease and human leukæmia, the possible relationship of viruses to cancer, and other questions.

Sessions of great interest to practising physicians and surgeons were the combined symposia of the Sections on Surgery and Therapeutic Radiology, with prolonged discussions on the value of pre- and post-operative radiation in the treatment of cancer of the breast, the proper method of handling node involvements occurring with cancer of the oral cavity, and similar problems which, since they have to be studied statistically on human beings, cannot yet be regarded as settled, because of the lack of extensive statistical records of patients treated in different ways.

The remainder of the programme was devoted to papers on roentgenological diagnosis, genetics, education and statistics, and other clinical and experimental investigations.

Owing to the present situation, it was impossible for the Executive Committee of the International Union against Cancer to make any decision as to the place of meeting for the next Congress. The delegates from South America, however, gave a very cordial invitation to the officers urging the suitability of Buenos Aires for the Fourth International Cancer Congress in 1942.

SAFETY IN MINES RESEARCH BOARD

THE seventeenth annual report of the Safety in Mines Research Board for 1938 has recently been published*. In referring to safety instruction, it is pointed out that teachers, managements and trade union officials are convinced of the value of safety instruction. Safety principles classes for boys are established in every coalfield and similar classes are being formed for adults. Many applications for permission to attend demonstrations at the Research Station, Buxton, have had to be refused on account of lack of accommodation, but during the year there were twenty-two demonstrations which were attended by 5,983 visitors, of whom 3,864 were adults and 2,119 were boys. After demonstrations of coal dust explosions, methods of firing shots and the testing of electrical appliances, discussions were held, usually initiated by some member of the research staff. Many lectures have been given in the coalfields by members of the staff to an estimated total of 16,000 persons.

Cinema Films, Lantern Slides and Exhibits. The Board has prepared cinema films, lantern slides and exhibits, which have been used by teachers and safety officers in connexion with their work. One hundred and twelve loans of cinema films, representing three or four hundred exhibitions in addition to two hundred exhibits, have been made, which indicates the popularity of this branch of the Board's work.

Dispersability of Stone Dusts. An underground gallery at the Station has been used for comparing the dispersabilities of dust deposits during explosions. Various stone dusts have been used separately in thin layers, and as mixtures alone and with coal dust. Work on this problem is being continued, but it can be stated that improvements in the dispersability of dusts is obtained by the addition of light precipitated carbonates. Carbon black causes remarkable improvement. The minimum speed of an air current required to disperse weathered gypsum is 3,400 ft. per minute, whereas with the addition of only 1 per cent of carbon black this speed is reduced to 2,100 ft. per minute. The nature of the action is being studied, but obviously a disadvantage in the use of the mixture is the darkening of the dust, which affects the illumination of roadway.

'Water-proofing' of Colliery Stone Dusts. If ordinary stone dust comes in contact with moisture either in the atmosphere or on the surfaces of roadway in mines, it will not retain its dispersability. Both in Great Britain and in the United States, dusts have been produced which are not readily wetted by water. The dust is ground limestone, with which is incorporated ½ per cent of palmitic or stearic acid. These dusts are highly dispersable and resist damp atmospheres extremely well. Incidentally, the fatty acid protector is readily incorporated during the grinding of the dust, and there appears to be no reason why the process should not be applicable to other dusts.

Gob-fire Experiments. For many years work has been proceeding on gob fires. In the experimental chamber, heatings have taken place when warmed air has been passed through packs consisting of coal and dirt. This state has been reached when the ingoing air has been at temperatures as low as 150° F. The he ings have been within a foot or two of where the entered the pack.

In one experiment the chamber was filled w coal from the roof coal above the Barnsley Bed l than 3 in. in size, of which one third was ground pass through a ¼-in. sieve. After ten weeks a heat occurred. The temperature of the air was raised stages from 160° F. to 212° F. and the rate of f varied between 0·5 and 10 cubic feet per minu A heating developed when the rate of flow v 5 cu. ft. per minute.

A similar experiment was carried out but with fine coal, and a heating developed in four wee When the temperature of the air was raised fr 185° F. to 200° F., the carbon monoxide content the return increased in six days from 0·002 per c to more than 0·024 per cent.

Noise. Another interesting investigation is t concerned with the reduction of noise. It has b found that the proper maintenance of mechan details and attention to the air exhaust is necess to obtain substantial noise abatement. A silen has been designed for use with pneumatic pi which adds 1¼ lb. to the weight of the pick, equival to an increase in weight of 7 per cent. Good res have also been obtained by piping the exhaust from the road rippers on the surface, and whilst t idea cannot be applied to portable machines und ground, it might with advantage be used in connex with stationary engines. The metallic ring can reduced appreciably by drilling a ¼-in. diameter h at a distance of about 12 inches from the shank the pick steel and filling it with molten lead plug with a steel cap.

Experiments are being carried out on sou absorption in connexion with the silencing of elec motors.

Health Researches. Experiments are in prog at the Physiological Laboratory, St. Bartholome Hospital, on dust inhalation and rela problems. Cages of guinea pigs have b placed at selected positions at collieries work anthracite, and a large number of lungs have b examined. It has been noticed that the lungs animals from the screens contain more dust th those of animals kept underground. Much work been done on dust suppression, and with the aid wetting agents it has been possible to design pl using: (*a*) a compressed air mist; (*b*) a mechanica formed mist; (*c*) turbulent passage through wat and (*d*) filtration by means of a compressed me wool mattress. Under practical conditions consid able improvement has been effected by the use these appliances at loading points underground in connexion with screening on the surface.

With regard to poisonous gases it has b shown that a high degree of protection agai carbon monoxide can be obtained with commercial canister. When tested against a 1 cent mixture of carbon monoxide in air satura with water vapour at 17° C. and flowing at a rate 32 litres per minute, each canister had a total leak of carbon monoxide of 960 c.c. in four hours, wh is the limit set in the official tests of the Uni States Bureau of Mines.

ARCHÆOLOGY IN PERU: RECENT PROGRESS[*]

HE sequence of cultures in Peru was first established on a scientific basis by the excava- ns of Max Uhle at Pachacamac and Moche; and is was in the main confirmed by A. L. Kroeber's d expeditions of 1925–26 and his classification of e Uhle collections in American museums; but the tecedents of the earliest and finest cultures, such the Early Chimu and the Early Nasca, are still known. Dr. J. Tello's intensive field researches ve led him to the conclusion that the Coast cul- res were to some extent derived from the Highlands, sagreeing in this and in other respects with the le-Kroeber scheme. He regards the 'Archaic dean' as the earliest, extending throughout the ghlands. Dr. H. U. Doering has recently found Pacatnamú superimposed burials, of which he gards the oldest as having 'Early Chimu' affinities. In the Highlands, the Tiahuanaco cultures are nerally recognized as being considerably pre-Inca. e cyclopean buildings of the Cuzco region have en supposed by some to belong to a pre-Inca galithic period. A detailed study of the masonry which cyclopean, megalithic, and ashlar styles are ten intimately blended, now makes it difficult to stain this view. H. Bingham's investigations at chu Picchu provide good evidence of this blending styles; but the pottery is typically Inca. In 1933 e Peruvian Government established an Archæological Institute at Cuzco in celebration of the fourth centenary of the foundation of Spanish Cuzco, and inaugurated an extensive programme of clearing, restoring and excavating on the sites of the Cuzco region.

Hitherto unknown buildings have been revealed above the citadel of Sacsahuaman, and much pottery and other artefacts have been excavated. All the architecture is purely Inca; but the Incas used different styles for different purposes, often combining two or more styles in the one building. The pottery is almost without exception of Inca types.

The use of radiophotography in the laboratory of the British Museum recently by Dr. H. J. Plenderleith and Mr. A. Digby has afforded interesting results regarding the technique of handle and spout attachment, which may prove of value in classification, dating, and tracing influences from one region to another.

Air photography has been used in recent years and led to the discovery and plotting of the 'great walls' of Peru flanking the Santa River in 1932.

Dr. Valcarcél has appealed recently for international co-operation in Peruvian archæological excavation, for which local resources are inadequate. It is to be hoped that British field archæologists will give some attention to the Peruvian area in the future, and that the study of American antiquities may be encouraged and placed on a sounder basis by the establishment of special departments for the subject in some of our universities and museums.

MARINE DEPOSITS OF THE ARABIAN SEA[*]

NVESTIGATING the many samples from 131 stations the author determines the distribution the main types of marine deposits in the Arabian a. The new data confirm the essential facts given Sir John Murray's latest chart. The transitional lobigerina ooze - red clay, however, is indicated parately on the new chart, as this mixed deposit is equently difficult to assign to one or other of the mponent types. In several cases the distribution the pelagic deposits is correlated with water ovement, as in the Zanzibar Area. The Pteropod ze in certain areas is shown to be correlated with e hydrographic conditions which cause a lack of ygen and increased salinity resulting in a high ath-rate in these molluscs. Special attention is ven to the biological remains in all the samples as evious authors have worked mainly from the ineralogical and chemical point of view. The remains organisms in the deposits have been separated out d the percentage remains of each of the common yla determined. The total percentage of remains the deposits is correlated with the depth, being gh in shallow water, low in 500–600 metres, and en rising again in about 1,000 metres. This rise the deep water is mainly due to the accumulation of Globigerina and other Foraminifera. Foraminifera are much the commonest constituents of these deposits, Globigerina being the chief genus which with other Foraminfera forms enormous areas of deep sea oozes. It is found that the green and brown muds have the largest foraminiferal fauna, and more than twice as many species occurred in the green mud deposits than in any other. In two instances only did any one species occur in great numbers—*Rhabdammina abyssorum* from a deposit of mud in the Gulf of Aden where the residue after washing consisted almost entirely of these shells, and *Dendrophrya ramosa* from a station in the Zanzibar area occurred in very large numbers.

The Priestman grab hauls give interesting results in the depth range of the larger animals obtained, and the different types of deposit are reviewed as animal habitats in the light of these hauls. It is found that green muds and the muds and sands from the lagoons are rich in life whilst grey muds and clays and light brown or yellow sands are almost without life. Certain groups are shown to live mainly or exclusively on the coarser deposits.

It is unfortunate that the coloured key to the separate chart of the Zanzibar area is very mixed up, the area of Globigerina ooze reaching out to the deep water and coloured pink being labelled Pteropod ooze, whilst the coral muds and sands are labelled Globigerina ooze and the Pteropod ooze is labelled Coral muds and sands.

SCIENCE NEWS A CENTURY AGO

William Murdock (1754-1839)

On November 15, 1839, William Murdock, the colleague of Boulton and Watt, died at his house, Sycamore Hill, Handsworth, at the age of eighty-five. He was buried in Handsworth Church, and his bust by Chantrey was placed there side by side with the memorials to Watt and Boulton. Murdock was born at Lugar, Ayrshire, on August 21, 1754, and after being trained as a millwright by his father, in 1777, at the age of twenty-three, entered the famous Soho works, Birmingham. In 1779 he was sent to Cornwall as an erector of pumping engines, and he remained there until 1798. Much of the success of the firm in the county was due to him. He was a man of fine physique, cool-headed, frugal, ingenious and resourceful. In those days only the principal parts of the engines were made at Soho and much remained to be done at the mine. Boulton spoke of Murdock as the finest erector he ever saw. In Cornwall, too, at Redruth, Murdock made his historic little model steam vehicle, and carried out his pioneering work on gas lighting. The latter formed the subject of a contribution by him to the Royal Society in 1808, for which he was awarded the Rumford Medal.

Returning to Soho in 1798, on the dissolution of the partnership of Boulton and Watt and the assumption of office by the sons of the founders two years later, Murdock became the presiding mechanical genius at the works, and during the next twenty years made notable contributions to mechanical engineering. The manufacture of gas-lighting plant was taken up in earnest and Soho may well be regarded as the cradle of the gas industry. Murdock also furthered the application of compressed air to machinery, constructing air motors and pneumatic lifts. His inventions included the sun and planet motion, cast-iron cement, a rotary engine, an improved boring machine, and the long D slide valve.

The United States Coast Survey

In its column of Weekly Gossip, the *Athenæum* of November 16, 1839, said: "We are glad to learn that at length some progress has been made in the survey of the coast of the United States of America—a subject of great interest to all maritime nations. So far back as 1807, a law was passed on the recommendation of Jefferson, authorizing the President to cause a survey of the coast of the United States . . . owing, however, to the external relations of the country at that period, the survey was, for a time, deferred . . . In 1832, however, it was recommenced with increased vigour. . . . From the report of the Superintendent, it appears that the work is completed throughout that part of the coast and adjacent waters lying between the eastern extremity of Long Island Sound, to the neighbourhood of Long Branch, New Jersey; and the necessary triangulations to pursue the survey have extended southerly to Cape May and northerly to Mount Carmel in Connecticut."

Ferdinand Rudolph Hassler, to whom the project was largely due, was born at Aarau, in Switzerland, in 1770 and, having made his mark as a mathematician, was engaged on a trigonometrical survey of his native country. Removing to America, in 1807 he was made professor of mathematics at West Point, and in the same year he submitted plans for a survey of the American coast. He died while directing the survey on November 20, 1843.

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned:

Director of the Geological Survey—The Secretary, C Service Commission, 45 Upper O'Connell Street, Dublin (November

Assistant in the Department of Physiology—The Secreta University College, Dundee (November 30).

Lecturer (Woman) in Mathematics—The Principal, Train. College, Lincoln.

MAN-POWER AND THE NEEDS OF YOUTH

'EW features of the opening weeks of the War have received more widespread approbation n the desire manifested in our general policy conserve human life so far as possible. If loss life is inevitable in warfare, strategy and tactics ve been designed to secure objectives with the nimum of loss, and to avoid the appalling wast- which so often characterized offensives in the r of 1914–18. The announcements that the lier age groups will not be among those first led up for service with the armed forces and t the former militiamen are not to be drafted mediately to active service units, the funda- ntal idea in evacuation schemes, and even the lundancy or waste in certain branches of civil fence against air attack which have been the oject of recent criticisms, are all signs that sons of the last war are being taken to heart. is realized that the man-power of Great Britain a most precious national asset, and a serious ort is being made to conserve it.

Welcome as such signs may be, we cannot ume that the lesson has been fully learned. n-power is as precious on the home front as the field, and the uneasiness and criticism re- rding the Ministry of Supply which have found pression are indications that concern exists ether the wisest use is being made of the tion's resources in labour and skill in the bilization of industry, to meet alike the demands the fighting services for munitions and of the riad essential home needs of a nation at war. en more disquieting, however, is the postpone- nt of the raising of the school-leaving age to een years, which was to have been enforced m September 1 last.

That an Act should have been passed repealing sections one to six of the Education Act 1936 cannot be viewed without dismay. A trenchant passage in the paper by Mr. W. O. Lester Smith, director of education for Manchester, which was read before a meeting of Section L (Education) of the British Association at Dundee seems now almost like a prophetic warning :

> "One of the great social tragedies of our time is our blindness to the needs of boys and girls in the adolescent period when schooldays are over. The wanton blow struck at the day-continuation school clauses of the Fisher Act by the Geddes Axe was probably the unkindest cut our educational system has suffered ; it has prevented local authorities from making a decent job of the youth problem."

Mr. Lester Smith goes on to point out that, of our three million young people between the ages of fourteen and eighteen years of age, one third only attend any kind of school, another third belong to some voluntary organization, while the remaining third—probably those who need it most—are completely out of touch with educational or wholesome social influences. Mr. Lester Smith's argument is powerfully supported by Dr. A. E. Morgan's recent report to King George's Jubilee Trust on the needs of youth, where it is maintained that the raising of the school-leaving age to fifteen years is not enough. We cannot afford to let even the boy or girl of sixteen slip out of our care and allow invaluable human capital to run to waste. A system of part-time continued education carried on during the working day up to the age of eighteen years is essential.

We are indeed far as a nation from realizing the difference it would have made if the Fisher

Act had been in force in the post-War years, or how far the shock given to our social life by the disaster of widespread unemployment might have been broken. The exasperating picture drawn by the Unemployment Board of youth going to seed after a flourishing beginning followed by lack of attention need never have been; the boys and girls whose lives were blighted by the effect of those drifting years might have found help and strength in the development of their minds. Nation and Government alike have been lacking in imaginative insight where youth is concerned. So far from recognizing the cruel wrong done by our neglect, the Government is now withdrawing the only big educational gain of this generation, and there are even those whose first reaction to the need for economy in the financial sphere is to press for the further squandering of the most precious form of our human capital. The recent announcement of the President of the Board of Education that a special committee has been set up to deal with juvenile welfare is a welcome sign, however, that the Government is not entirely indifferent to the matter.

It is recognized, of course, that under war conditions administrative arrangements necessary to make beneficial use of the extra year at school would be difficult and that the difficulties have been enhanced by evacuation. To base suspension of the raising of the school-leaving age on financial grounds, however, is reprehensible and dangerous, betraying an indifference to fundamental values that may well cause alarm among all who are concerned to see that our war-time effort is prosecuted as effectively as possible. The contention that the elaborate machinery for exemptions would be unworkable in present circumstances is equally invalid. Recognition of the real value to the nation of raising the standard of education during the formative years would lead us rather to abandon all exemptions, as indeed most educational authorities recommended originally.

It is indeed idle to expect real progress until the nation as a whole is awake to the value of youth as its ultimate capital—the bedrock upon which alone, as Dr. Morgan remarks, we can lay the foundations of real national fitness. Then indeed we might have the courage to repair this evil and not intensify it. To impose compulsory continuation education up to the age of eighteen might indeed put a strain on industry at a time when the war demands all its energy. That, however, is not the whole truth. Even more than the
nation needs munitions, it needs capable a
intelligent human power. So far as the immedi
needs of the war are concerned, it might be t
economy to take all boys and girls out of indus
for some hours every week for education. A
loss in material output would be more th
balanced by the improvement in the men a
women on whose spirit and capacity the nati
must rely for victory.

If we regard, as we must, the permanent nee
of the nation, the argument is more power
still. None can say how many of the difficult
of the last twenty years are due to the destructi
of talent and virtue by the last war itself, to t
loss of constructive minds, imaginatively alive
the fundamental issues. But some of the di
culties are doubtless due to our persistent
difference to the nation's larger needs, our failu
to strengthen the moral and intellectual power
the electorate to meet the demands made by wo
politics on their intelligence and imagination

The discussion on education as a preparati
for industry and on education in industry befo
the British Association at Dundee afforded welco
evidence that, at least in some quarters in industr
the higher standard of education demanded in t
leaders of industry, as well as in the rank and fi
for the successful conduct of industry to-day
now recognized. The wider recognition of t
value of a sound general education is all to t
good, and equally the dependence of progress up
co-operation between industry and education
authorities is gaining recognition.

It is indeed from co-operation in this way, t
development of contacts between the education
and the industrialist,and the fuller understanding
each other's point of view, difficulties and proble
that we may expect an informed opinion to emer
powerful enough to resist short-sighted policies
economies on the part of the Government. Alrea
many industrialists are alive not only to t
importance of part-time continued education, b
also to the importance of provision for the leisu
needs of adolescents. It is for the industrialists
join hands with the educational authorities in repr
sentations against policies likely to undermi
industrial efficiency and dissipate human capit

Dr. A. P. M. Fleming's fine presidential address
Section L of the British Association, a portion of whi
is printed elsewhere in this issue (p. 852), strikes t
right note in this crisis. Industry, he conten
is not concerned with the education of its person
in a narrow sense only. It recognizes increasing

at education for those engaged in industry must characterized by broad aims and linked up-with e outside world. It has proved its willingness co-operate with education and is increasingly sirous of recruiting those well trained in fundaental principles rather than in any special branch the selected science. It is turning its attention the problem of finding suitable personnel trained undertake the increasingly difficult problems of anagement. As this problem is solved, industry ill find itself provided with leaders imbued with e realization that every industry is in fact a national service, although it may be conducted by private enterprise; and as awake to the welfare of its workers as they are to the technical efficiency of the enterprise. Such leaders will ever be vigilant against the betrayal or waste of national resources, whether in materials or in men and women. Meanwhile, it is imperative that the importance of youth as a national asset should be fully recognized, and that every effort should be made to prevent a repetition of the disastrous mistakes of the last war period in the treatment or even exploitation of youth.

PSYCHOLOGY OF WAR AND PEACE

'ar and Peace
ssays in Psychological Analysis. By Dr. William rown. Pp. xvi + 93. (London: Adam and arles Black, Ltd., 1939.) 5s. net.

THIS book left its author's hands a few months before the outbreak of war, and though he s sanguine enough to say that the events at unich in September 1938 "saved the world from r at that time, and possibly for ever", yet his ok does not on that account lose any of its real lue. Dr. Brown is a well-known psychologist of definitely marked type. He writes here as a ychologist on the subject of war and peace, and would have done well if he had adhered idly to the scientific point of view, and avoided en distant references to his political convictions. e book would probably also have gained in eight and influence if greater care had been stowed upon clear and consecutive exposition. The book consists of six chapters, three of them lected from previous publications, together with number of letters contributed to *The Times*. e author's claim that these parts in their subct-matter belong together will not be disputed, t it must be added that if they are to "fall turally into their place as stages in the arguent", the reader must to a great extent make em do so. For the most part, Dr. Brown makes mself quite intelligible to people who are not udents of abnormal psychology, but the reader ould be warned that, after many pages free m technicalities, he is suddenly informed that e may cure or improve the hysteric, the psychourotic, but the psychotic still in the main apes us".

We have said so much because we believe that psychologist has an important message on the bject of war and peace, and because we are anxious that he should be understood by the ordinary intelligent citizen. Dr. Brown holds that unless the world applies psychology to its problems, as it has applied physics and chemistry, physiology and pathology, its pursuit of peace will continue to fail. His difficulty is that the man in the street thinks he knows all about psychology, as he thinks he knows all about economics—for has he not a mind of his own, and has he not much to do with credit balances and deficits? We cannot have a nation of experts, but we ought to have a far wider appreciation of the forces that make for war. Among the most fundamental of those forces are the tendencies to self-preservation, self-assertion or aggressiveness, acquisitiveness, and pugnacity. The activity of the group mind, with partial liberation of repressed mental forces, especially under the influence of a leader, also stands out as an essential factor in leading to the outbreak of war. Such are the main positions taken up and explained in Dr. Brown's book.

If we interpret Dr. Brown aright, he would say that in spite of all that has happened since this book appeared, his views remain unchanged. When the war ends, we must begin again to seek peace and ensue it, never yielding to a belief that war is inevitable. But, he holds, we shall never secure peace by orgies of pacifist sentiment. The more hopeful way is that of understanding human nature, especially those sinister forces which lurk in the unconscious of the best of us. "The tiger is there, and the wolf, and the jackal, and the snake, and we must not forget the donkey."

We conclude by expressing the hope that psychologists of different schools will do much more than has yet been done to throw light on the dark problems of war. Meantime, Dr. Brown has courageously led the way.

THE PLANNING OF LONDON

The Government and Misgovernment of London By Dr. William A. Robson. Pp. 484. (London: George Allen and Unwin, Ltd., 1939.) 15*s*. net.

As soon as the international situation permits, there can be little question that much more time and thought than hitherto will have to be concentrated on urgent problems in home affairs, among which the government of London stands pre-eminent ; and even if international affairs are still pre-eminent, that indeed may be cited as a principal reason why this matter should receive immediate and intelligent consideration, with a view to immediate and intelligent action, for it can easily be shown to be a primary factor in national defence. Dr. Robson emphasizes this aspect with convincing force, and also very appropriately at the beginning of his book insists that the proper government of London is a question of supreme national and not only metropolitan importance.

> "A dim realisation is dawning on the public that the size, growth and development of London have nation-wide effects which are felt ultimately in the remote quarters of Great Britain ; and many people have recently become aware of the sinister military significance of the immense concentration of population, wealth, and power in London ; but so far there is little or no understanding of the connection between these matters and the general administration and planning of London government".

Again, in the last chapter, at page 459, he urges the essential need for clear recognition of the fact that London's government is a national question calling for national leadership and direction ; pointing out that nothing would be more fatal than a complacent delegation of this vital and fundamental problem to the local authorities to settle among themselves.

Dr. Robson has to deplore that for half a century or more no Government has exhibited qualities of leadership, imagination, or determination in regard to this much-needed re-organization. In fact a striking, not to say an amazing, feature of the history of the metropolis during the past hundred years is the vast number of commissions and committees of all kinds that have studied, with great trouble and expense, some aspects or other of London municipal organization—or lack of it—and made excellent and desperately urgent recommendations on overwhelming evidence ; but nothing whatever has been done ! These pages are a record of innumerable lost opportunities, of feeble drifting, of supine indifference, and of a la of courage and imaginative foresight that absolutely appalling. Doubtless the opposition vested interests, municipal or otherwise, has som times been exceptionally powerful and w organized ; and the share of the City Corporati in this respect is not too creditable. But the tr issues and their importance have been clea realized by acute observers from the time of t first emergence of the problem, long before reached its present huge and almost unmanageal shape. Among others it was thoroughly grasp by the Royal Commission on Municipal Corpor tions (second report in 1837), and by the Select Co mittee of 1838. In 1852 Mr. Toulmin Smith sa that "the present condition of this huge metropo exhibits the most extraordinary anomaly in En land. Abounding in wealth and in intelligen by far the greater part of it is yet absolute without any municipal government whateve (page 56).

Of books on London, besides innumerable Bl Books, there is no end ; and several of the mo important are given in the footnotes. Of planni and reform talk there has been likewise a swelli flood, and yet, as Mr. Pick, of the London Pa senger Transport Board has pointed out (quot on page 415): "Town-planning does not rea exist at all in London at present. What goes the name is almost idle and useless so far, and h not yet arrived at a conception of the congeries towns that make up a metropolis." Elsewhere like many others who have seriously studied t matter, fully acknowledges the need for unifi control of an aggregation of people in a sin social, economic, geographical unit. "Aggreg tion", whilst apt enough for the present hete geneous dismembered mass of London humanit is not perhaps the best term for that migh co-ordinated community which, despite politic and local differences which may persist, will breathe as one vast organism, aflame with ci ardour, and united in one common bond of mu cipal loyalty. That dream of the future shou not be long delayed in its realization ; and it m be said at once that it does not mean that local differences and governments will be who sunk and immersed in one dominating form control.

Dr. Robson's main idea, in fact, is the establis ment of a Greater London Council, which shou be the one supreme authority in an administrati area very much greater than that of the prese

C.C., and with far wider powers. It would take le charge of certain important functions where ified control is most essential, and would exercise ly supervisory powers over the local authorities matters which should preferably be left mainly der their control. There would also be a third tegory of activities which could be left wholly local control. The number of authorities, hower, would be much less than the present bewilringly numerous collection, and their respective eas would be correspondingly larger. Certain *hoc* bodies like the London Passenger Transport ard would doubtless have to remain, provided me means were established for the better codination of their functions with the general ntrol; but the county councils on London's rders would probably have to relinquish or dicate their powers which, under the new rangement, would be unnecessary and merely structive.

The book is a very fine piece of work, the result Herculean labours and research of existing terial, with much original and constructive ggestion of its own. It exhibits in a marked gree literary qualities of a high order, and the en analytical powers of a trained legal mind, gether with a sustained interest almost unique studies of this kind. Interest, indeed, is intensid both by the very special and unprecedented ture of the subject-matter and by the method of treatment. There may be differences of opinion in matters of detail, but as to the main recommendations of the author there can surely be little question or quibble among intelligent people.

The difficulties in the way of reform are doubtless formidable, but that is no ground for shirking or further postponing the issue, which presses clamorously and insistently for early action. The historical background as well as the sharply critical treatment of the present muddle and confusion show clearly enough that action of some kind is long overdue.

Among the many valuable features over which one would wish to linger there is only one of which exigencies of space will allow mention: Dr. Robson continually emphasizes the paramount need for awakening the interest of the individual elector; but not content to leave it there, he suggests several ways in which this urgent need may be supplied (pages 67, 171–73, 279, 314, 324–25, 330, 351), or indicates reasons why it is lacking. To the suggestions already made perhaps one may be allowed to add another, namely, that a smaller and cheaper version of Dr. Robson's work would perhaps more effectively reach the teeming millions of London who are most nearly concerned, as well as the general public throughout Great Britain, who also must give some thought to this vital matter of the government of London.

W. G. L. C.

INTRODUCING BIOLOGICAL PRINCIPLES

imals without Backbones
Introduction to the Invertebrates. By
lph Buchsbaum. Pp. x + 371 + 128 plates.
icago: University of Chicago Press; London:
mbridge University Press, 1938.) 25s. net.

WHEN one reads that an attempt is being made to present a zoology text-book in mple, non-technical language", one's first reion is invariably that of suspicion. In the jority of cases the authors of elementary logy text-books fall between two stools. In desire to preserve an easy and popular approach book often takes on a bias towards natural tory, and although serving to describe the bits and characteristics of many animals, is nerally lacking in morphological detail and in oretical principles. On the other hand, in der to present the academic point of view, a ok not infrequently becomes a mere comndium of technical terminology and minute ail in which fundamental issues are obscured. Fortunately (for our introductions to invertebrate zoology are very limited) this book belongs to neither of the above classes. Each group of animals is treated in such a way that it illustrates some general principle of biology or some level in the evolution of animals from simple to complex forms. In this account of the lower group of animals, Dr. Ralph Buchsbaum combines an extensive practical knowledge of the subject with that rare propensity for making the 'wood' apparent without neglecting the individual 'trees'. The sequence of the book is based on the course given to students at the intermediate grade in the University of Chicago, and the author has been fortunate in having the active collaboration of the staff of the Zoology Department there.

A particularly interesting feature of the book is the liberal supply of drawings. These, together with the numerous photographs, immediately command and later compel attention. The photographs, which are intended as a sort of laboratory exhibit and vicarious field experience, are extremely profuse—there are ninety-eight insect photographs alone—and represent a new approach in the production of biological text-books. The drawings are original, are mostly diagrammatic and have been prepared as an adjunct to the author's attempt to expound biological principles rather than to confuse the student with meticulous attention to detail; they are generally designed to convey *ideas* about structure, function, or habit. Much of the attractiveness of the book is due to these unusual diagrams, many of which are 'three-dimensional'; a tribute by the author to his sister, Miss Elizabeth Buchsbaum, for her "skilful and artistic execution of the drawings" is richly merited.

The text contributes to that clarity of outlook which is revealed by the diagrams and photograp emphasis being constantly placed upon principle involved rather than upon the de connected with it. Occasionally, with a revuls for the use of extraneous terminology, the aut carries his simplification too far; this is seen his disinclination to use zoological nomenclat as complementary to the local name. Since book is American, some of these local nar would be quite unfamiliar to British stude There are some inaccuracies, but these are r and one can readily believe that this book soon find its way to many bookshelves. That is already appreciated is borne out by the f that a second impression was printed just t months after the issue of the first.

T. H. Hawkins

MANUFACTURE OF CALCIUM SUPERPHOSPHATE

Calcium Superphosphate and Compound Fertilisers

Their Chemistry and Manufacture. By P. Parrish and A. Ogilvie. Pp. xiv + 322. (London: Hutchinson's Scientific and Technical Publications, 1939.) 35*s*. net.

SUPERPHOSPHATE is one of those chemicals that are almost indispensable to civilized man and never put by him to base uses. It commands our interest for several reasons. Its value for increasing world supplies of food and fibres has been proved on all five continents, and the annual consumption of it now exceeds sixteen million tons. It was the first so-called 'artificial' fertilizer to be manufactured on a large scale, by J. B. Lawes in Great Britain, where also its use as a simple fertilizer and as a base for 'compound' manures was first developed.

Some thirteen years ago the present authors wrote a book on superphosphate to which they gave the too general title of "Artificial Fertilisers: Their Chemistry, Manufacture, and Application", and the present work is a revised and extended version of it with a more accurate title, though even this is somewhat invalidated by the added chapter on basic slag. The subject as treated will appeal to the technician, and especially to that notable example of technical 'hybrid vigour', the chemical engineer; the language, too, is technical, and the authors themselves would not claim to have produced a rigidly scientific or a literary treatise.

The bulk of the book relates to the manufacture of superphosphate, to the plant used and the operations involved in grinding and crushing phosphatic raw material, its treatment w sulphuric acid in various types of 'den', drying, storing, handling and bagging of product. Conveying machinery is well describ and interesting data are given concerning manufacture of sulphuric acid from spent ox and the preparation of 'compounds' by mixi Apart from the omission of several kinds of fi grinding plant used in Britain or abroad, mechanical part of the subject is well done; numerous photographs and line-diagrams particularly good, whilst the sensible treatm of financial outlay and working costs is also be commended.

If the authors had confined themselves to above matters, and had expressed themselves better style, there would be nothing but pra for the book. It is no doubt owing to the l of a clear and succinct style that they se to tread on thin ice when they assert that "me phosphoric acid is a product of overheatin that "pyrophosphoric acid only occurs in s stances which have been subjected to heat", that "the calcium salts of orthophosphoric a are found in all phosphatic fertilizers. . . The same reason can scarcely be advanced for surprising statement that water combines w monocalcium phosphate to form hydrated cryst of calcium sulphate. Recent X-ray analysis shown that only a small proportion of calcium sulphate which is present in sup phosphate is in the hydrated form, so that planations based upon the old view are outmoded.

References to "concentrated fertilizers" are apt confuse the reader unless he understands the ference between those based upon ammonium osphate, like the German 'Nitrophoskas' and e English 'Concentrated Complete Fertilizers' .C.F.'s) that were first marketed in 1926 and 30 respectively, and the projected new con- ntrated fertilizers that are based upon super- osphate. The authors' sweeping statement that n the early trials the concentrated fertilizers re found less efficient than the compound anures, and their use began to decline after a w years" needs correction. Apart from a few lated failures, mainly with the American mmophos' and with 'Nitrophoska' in the United ates about ten years ago, the early trials, conducted on strictly scientific lines, were very successful. Sales of Nitrophoska increased spectacularly until the world depression in 1931, when they fell, but have gone ahead since, whilst sales of C.C.F.'s have increased continuously and markedly from the start.

Few of those who know the requirements of British crops and soils will dispute the authors' opinion that there is still scope for the greater use of fertilizers, but the suggestion that the fertilizer industry, and in particular the superphosphate industry, should be better represented in Parliament opens up, by implication, a vista of trade representation and commercial flag-waving in that august assembly which would be entirely foreign to its honoured traditions.

THE STEAM ENGINE AND ITS DEVELOPMENT

Short History of the Steam Engine
H. W. Dickinson. Pp. xvi + 255 + 11 plates.
ambridge: At the University Press, 1939.) 15s. net.

HIS is the most important work on the history of steam engines published since 1908, when . C. Matschoss's "Die Entwicklung der Dampf- schine" appeared under the auspices of the rein Deutscher Ingenieure. But whereas Dr. tschoss's work ran to two volumes each of re than 700 pages, and dealt with all types of gines, including locomotives and marine engines, . Dickinson's book is on a much smaller scale, d is devoted entirely to stationary engines.

As is well known, Dr. Dickinson spent some rty years as a keeper at the Science Museum, ndon, and the catalogue of stationary engines, ntaining information about more than five ndred exhibits, was prepared by him. But he no dry-as-dust compiler and is as interested in lives of inventors and in industrial progress as is in the machines themselves. In this volume has therefore been able to incorporate the ults of the researches of such as Mr. Rhys nkins into the early history of heat engines, the ults of his own inquiries into the lives of ulton, Watt, Trevithick and others, and a neral review of boilers, engines and turbines ce the steam engine began to revolutionize lustry in all its ramifications.

There are fourteen chapters in the book, of ich five deal with the work done in the seven- nth and eighteenth centuries, four with the gress of boilers and the reciprocating steam gines during the nineteenth century, and four th modern boilers and steam turbines. There is also a chapter on the philosophy of the steam engine. In addition, there is a reproduction of a synopsis of events in the history of the steam engine exhibited at the Science Museum, and a good index.

Though in a brief notice it is not possible to touch upon the many interesting developments in steam machinery set out in the book, many readers, we think, will find entertainment in the excellent account given by Dr. Dickinson of the Newcomen engine, which proved of such outstanding value and importance. Belidor, the celebrated French engineer and architect, said in 1739 of this engine that it was the most marvellous of all engines: "Heat is its principle of movement; in its various pipes it creates a circulation like that of blood in the veins, having valves which open and shut opportunely; it feeds itself; it discharges itself at regulated times and draws from its own work all that it needs to subsist". No less marvellous are the boilers and turbines found in the power houses of to-day, and the end is not yet.

To all the developments of the last 200 years a whole host of ingenious men have contributed, and in his well-balanced, impartial and authoritative review, Dr. Dickinson has endeavoured to do justice to all those who made contributions of outstanding merit. The portraits given in the book are those of Papin, Smeaton, Watt, Evans, Trevithick, de Laval, Rateau, Parsons, Curtis and Ljungström. These were the pioneers of the reciprocating engine and of the turbine; but between these groups of pioneers were scores of notable inventors to whose labours attention is directed in the text. Altogether this history should prove a most useful book.

ONE HUNDRED YEARS OF MICROSCOPY

The Royal Microscopical Society

By Prof. R. Tanner Hewlett

THE Microscopical Society of London, now the Royal Microscopical Society, was founded in 1839, and it was proposed to celebrate its centenary this October with a special meeting. This function has been postponed for the present, but papers on the progress of microscopy during the last hundred years, contributed to celebrate the occasion, will be published in ensuing numbers of the Society's *Journal*.

In the earlier part of last century, microscopy was beginning to attract considerable attention, and not only among men of science, for public exhibitions with the microscope were given in London about 1833. This development owed much to improved instruments and to improvements in the lenses about this time. The first English achromatic lenses for the microscope were made by Tulley, an instrument maker of Islington, in 1825, at the instigation of a Dr. Gurney. Then in 1830, J. Jackson Lister, father of Lord Lister, devised improved formulæ for "working [achromatic] object glasses of short foci and large aperture, with a view to increase the power and ease of manufacture", and his paper did much to stimulate the production of better microscopes and their more extended use.

In 1839, several votaries of this new science of microscopy lived in Wellclose Square, near Tower Hill, including J. S. Bowerbank, authority on sponges, N. B. Ward, of "Wardian glass-case" fame, Edward Newman, the entomologist, and the brothers Edwin and John Quekett, whose name is perpetuated in the Quekett Microscopical Club. These and several others met at Edwin Quekett's house on September 3, 1839, and on a proposal by Bowerbank decided to form a society for "the promotion of microscopical investigation, and for the introduction and the improvement of the microscope as a scientific instrument"—aims which it has always been the endeavour of the Society and its fellows to fulfil. In December of that year, the Society came into being, with Richard Owen as its first president, Ward as treasurer and Dr. Arthur Farre as secretary. J. J. Lister was one of the original members, and Michael Faraday joined in 1841 and remained a member until his death. The Society was incorporated by Royal Charter in 1868, during the presidency of James Glaisher, and the reigning Sovereign has since been its patron.

Owen delivered his presidential address February 1841, on "The Structure of Fossil Tee from the Old Red Sandstone indicative of a n Genus of Fishes (*Dendrodus*)". Of the roll eminent men who followed Owen as presidents the Society may be mentioned John Lindley t botanist, Thomas Bell and George Busk, zoologis W. B. Carpenter, John Quekett the histologi W. Kitchen Parker, H. C. Sorby the spectroscopi Lionel Beale, W. H. Dallinger, E. M. Nelson, C. Hudson, Lord Avebury, Sir Ray Lankester a Sir J. Arthur Thomson.

During the first forty years of its existence, t proceedings of the Society were published succe ively in certain journals, but since 1878 the Socie has issued its own *Journal*, which in addition its proceedings, contains abstracts of the worl literature on microscopy. The Society maintai an extensive library and a cabinet of more th 20,000 representative microscopical specime including many 'type' specimens of diatoms a other forms of minute life. It also possesses unique collection of historical instruments.

The following brief survey of communicatio appearing in the Society's *Journal* will serve give some idea of the contributions made fellows to microscopy, though representing but fraction of the matter contained therein. Referen to articles by living fellows, which have appear during the last few years, is also omitted, wi one or two exceptions.

Dealing first with the microscope and its acc sories, an outstanding achievement was t formulation in 1858, with subsequent revisio of a standard screw-thread for objectives, n universally adopted by makers all over the worl As a result, an objective by any maker will fit t nose-piece of any microscope. The Society h likewise drafted specifications for the sizes of ey pieces and sub-stage fittings which have be generally adopted.

In 1854, F. H. Wenham contributed a paper "The Application of Binocular Vision to t Microscope", and described his binocular mic scope, and J. W. Stephenson described his "ere ing" binocular microscope in 1870. T. Maltwo in 1858 designed his "finder" for registering t position of objects mounted on a slide, and t description of the construction of an iris diaphrag was given by J. H. Brown in 1867. A malachit reen cell for monochromatic illumination was escribed by J. W. Gifford in 1894, and the glass-d illuminator by J. W. Gordon in 1907, and eith Lucas in 1904 designed a stand in which eometric slides replaced the usual planed nes.

Numbers of papers are to be found on microopical optics, to which E. M. Nelson made otable contributions, and about 1879 the question f lens-aperture and of microscopical resolution ccupied much attention, and numerous papers ere devoted to these subjects. In that year, bbe defined "numerical aperture" as we now nderstand it, and stated that for immersion puroses cedar-wood oil had proved the most suitable uid.

In 1865, Huggins and Browning first dealt with e application of the spectroscope to microscopy, d later H. C. Sorby contributed much to microectroscopy, incidentally, in his presidential ddress to the Society in 1870 surmising the ssible existence of "invisible germs", thus ticipating by some thirty years any positive nowledge on ultra-microscopic organisms.

There are naturally many contributions on hoto-micrography, commencing with a paper On the Application of Photography to the Reprentation of Microscopic Objects" by Joseph elves in 1853.

As in the "brass and glass" department, as we reverently call it, so a vast amount of material as been contributed on the biological side. iatoms, presenting as they do problems in the terpretation of the microscopical image, and as eing a most interesting group, both fossil and ving, have always been a favourite subject of udy, and are dealt with in numerous papers by allich, Greville, Kitton, Petit, Flögel and others. he Foraminifera have also been much studied; arly papers on the group were contributed by . Rupert Jones, and more recently by H. B. rady and F. Chapman, together with the notable apers by F. M. Millett on Malay forms, and by eron-Allen and Earland on the Selsey, North ornwall, North Sea and other species. Rotifers re likewise the subject of numerous papers by . T. Hudson, P. H. Gosse, V. Gunson Thorpe, ames Murray, C. F. Rousselet and others. T. H. uxley contributed a study of the rotifer *Lacunuria socialis* in 1853.

The Infusoria are dealt with by Saville Kent, . T. Hudson, Dallinger and Drysdale and Dallinger. The latter, in 1880, determined the thermal eath-point of monads in natural surroundings o be for the mature forms about 140° F. Dallinger n 1887 also worked on the gradual acclimatization f certain monads to increasing temperatures, and as able finally to maintain them without harm at a temperature of 155° F. E. M. Crookshank and H. G. Plimmer dealt with parasitic flagellated Protozoa. The mites are the subject of a number of papers by A. D. Michael, which deal with their structure and taxonomy and with new species, and Rupert Jones wrote on the Entomostraca and Saville Kent on siliceous sponges.

Parasitology is represented by several communications, commencing in 1849 with one by George Busk on the guinea-worm parasite of man. He remarked that infection is derived from water and that the worm is always female in its attributes; statements that stand to-day, for even now the male is almost unknown.

On the botanical side, contributions on the Bacteria are relatively scanty, probably because microscopy is rather subsidiary to culture methods for their study. There are, however, papers by R. L. Maddox on bacteria in the air and in rain-water and hail, and on lactic ferments, by E. M. Crookshank on Actinomyces and by Cheshire and Cheyne describing *B. alvei*, supposed to cause foul brood of the honey bee. In 1884 Lionel Beale described the microscopical examination of twenty-five samples of Thames mud, taken between Gravesend and Chelsea, for the presence of bacteria, determining their relative numbers at the various localities, and he remarked that if only the vast quantities of water in the upper Thames in time of flood could be husbanded for times of scarcity, there would be ample water to flush London's sewers and to keep the lower Thames from being fouled—surely a presage of the later work of the Metropolitan Water Board.

Many new micro-fungi were described by G. Massee, and other papers on this group were contributed by Miss Lorrain Smith and A. Chaston Chapman. Freshwater algæ are dealt with in many papers by A. W. Bennett and W. and G. S. West, and the bog mosses by R. Braithwaite. There are also many papers on vegetable structure, pollens, cytology and chromosome structure, and W. Carruthers and D. H. Scott dealt with the microscopical anatomy of fossil plants.

There are a goodly number of papers on animal histology, notably by John Quekett, Lionel Beale and C. da Fano, and W. Kitchen Parker contributed several studies on the development of the skull in birds, etc. In 1849, R. Warington described a new medium for mounting organic substances as permanent microscopical objects; this was glycerin, and he outlined the method of sealing the mounts with various varnishes. R. J. Farrants, president in 1861–62, devised the well-known Farrants' mounting medium.

There is no space to record many other important contributions, particularly those on the technical applications of microscopy to iron and steel, clays, petroleum, fabrics and fibres, and others, and to medical science. Many of the subjects referred to in this account are discussed more fully in the papers contributed in honour of the Society's centenary, which, as mentioned, are to be published in the Society's *Journal*.

In conclusion, we may express the belief that the Royal Microscopical Society has throughou its history sedulously pursued studies associate with problems of microscopic structure an function, and has contributed in no small measur to the development of the microscope as a scientifi instrument, and to its applications in science an industry.

EDUCATION FOR INDUSTRY*

By Dr. A. P. M. Fleming, C.B.E.,

Metropolitan-Vickers Electrical Co., Ltd.

THE evolution of industry involves a continual change in the character of the knowledge that must be applied by those engaged in it, if they are to achieve a continually increasing efficiency of production. How important this question of efficiency is to the whole community of an industrial nation may not always be appreciated. The material progress of civilization demands an increasing supply of manufactured products of all kinds. If they are manufactured at home, employment is increased and money is available for circulation. This affects eventually all the community and not merely those workers directly engaged in industry. It is therefore of vital importance that the transformation we speak of as industry shall be conducted with the utmost efficiency, and to achieve this the personnel engaged in it must be most effectively trained; which in its broadest sense means most effectively educated.

Industrial personnel can be divided into two main groups: manual and non-manual workers. The first requirement of the manual worker is practical handicraft skill, and of the non-manual worker specialized knowledge applicable to the function he performs in the particular branch of industry concerned. To satisfy these requirements well-organized schemes of theoretical and practical training must be made available to all those fitted to take full advantage of them.

There are four main classes of entrants into industry, namely, those who enter at the school-leaving age from elementary, junior technical, central and secondary schools; those from secondary schools who have attained School Certificate or Higher School Certificate standard; those who have had university training; and those adults who enter at any age and from any educational level. Of the first three classes, the university group contains the smallest proportion of misfit At the lowest entry level, economic need an local conditions of employment may, and usuall do, determine the choice of vocation. In additio there is still considerable social prejudice in favo of the so-called 'black-coated' occupations. Th importance of vocational guidance in the earl years cannot be too highly stressed, and althoug good work is being done in this direction muc more is needed; it should in fact be accepted as responsibility by every competent teacher. Su acceptance implies, of course, familiarity wit local conditions and opportunities. One usef adjunct might be the keeping, from school ent age onwards, of a record of the particul characteristics, aptitudes and preferences displaye by the pupil. Such a record would be of conside able value at the time when discrimination made between secondary, junior technical ar junior commercial schools.

For those entering industry at the lowest sta there is, at present, little conscious preparati for industry from the educational point of vie other than that in the junior technical schools. Th practical industrial bias given in these schools, f at least the final two years, is of definite advantag A much greater proportion of junior technic school pupils who enter industry advance rapid than is the case with their fellows not so educate Indeed the tendency is for many of them to recruited to the ranks of foremen, junior manage draughtsmen and so on, with the result that t equally important field of artisanship is not ve well fed numerically from this source. Records one factory, compiled over a period of years, sho that whereas 64 per cent of the entrants fro elementary schools became artisans, less th 10 per cent of the entrants from junior technic schools did so, in the same period.

The type of industrial training required for t manual worker who aspires to learn a trade acquire a craft consists of a long period of practi

---

* From the presidential address to Section L (Educational Science) of the British Association, delivered at Dundee on August 31.

perience with the tools, materials and processes
his chosen trade or craft, and accompanying
ssroom education which may be secured by
ening study in a local part-time institution, by
rt-time day training, or in a works' school
ring working hours. The character of these
dies varies considerably, but it is becoming
reasingly desirable that they should lead to
tional Certificates, as a course of this type
vides sufficient basic technical knowledge.
oreover, it provides a good basis for further
dy for the youth who is worthy of promotion.

For those youths who do not aspire to technical
ployment and whose natural bent is of a
re practical character, the workshop courses
vide an admirable adjunct to their practical
perience.

Those who enter industry at the School Certificate
Higher School Certificate level have usually had
advantage of a preliminary science preparation,
ich facilitates their acquisition of industrial
cess experience. Moreover, their higher general
cational level makes it possible for them to
ain staff positions where their more maturely
eloped powers of judgment and their social
ributes are of advantage.

Those who enter after university training have
eady acquired a considerable amount of know-
ge of the technological and fundamental
nciples required in the particular branch of
ustry they select. A high degree of specialization
this stage is extremely undesirable. It is of
greater value to be well versed in the funda-
ntal principles of the selected and associated
ojects. Indeed the latest tendency in industry
for any specialized training that may be required
be provided by the concern itself a year or two
er entry.

Much attention is now being devoted to the
oblem of finding suitable personnel trained to
dertake the increasingly difficult problems of
anagement. This is a matter of vital importance
ensuring continuity of progress in manufacturing
ncerns. It is essential that the selected men
ould be given preliminary and widely applied
sponsibility before making use of such aids as
ancillary instruction now available in many
hnical institutions.

Recruitment for research work in industry is
other case where the selection of personnel
erently suited for such work must be the basic
tor. Methods of training research workers are
ginning to evolve, but so far no recognized plan
established. In my own laboratories, general
prenticeship in the factory is followed by
perience in several of the laboratories under the
idance of experienced research workers, supple-
nted by lectures on the work in their own and associated fields by senior members of the department. In some cases such workers are sent back to a university or other research laboratory for further experience.

There is a natural tendency to concentrate attention on those engaged in some form of handicraft skill or technical operations for which particular education and training are required. It must not be overlooked, however, that there are vast numbers of young men and women engaged in clerical and other branches of employment in industry. For the most part, however, their education and training can be adequately satisfied by the existing facilities.

The normal trend of industry and its corresponding educational requirements can to some extent be forecast, though contingencies arising from an abnormal international political situation may disturb this.

New scientific knowledge with its technical application is likely to continue to be a determining factor in industrial development. Continual improvement in efficiency of production tends to reduce the amount of labour required, and to that extent accentuates the unemployment problem. On the other hand, out of scientific discoveries new products, processes and materials arise, and these, through the formation of new industries, contribute towards redressing the balance of employment. The film and the radio industries may be cited as examples of large-scale employment brought about by the technical application of scientific discovery. Such developments, however, emphasize the need for mobility and adaptability on the part of the personnel employed, because new industrial activities demand modifications to established handicraft technique as well as to the planning and organization of production.

It is apparent that the mechanization of processes, more particularly where repetitive work is involved, will become more extensive, and this should ultimately result in the securing of the necessary volume of production in shorter working periods—especially if employment could be more evenly distributed. Some of the time then available for additional leisure might be well employed in education of a cultural and social character and in physical training. By suitable planning it should be possible to reduce and eventually to eliminate the system of part-time evening study. The deficiencies of this system of technical education for those engaged in industry are well understood, but whether technical study is conducted in part-time day or part-time evening periods, the practice of compressing a large amount of highly specialized knowledge into intensive courses should be avoided.

While appreciating the present usefulness of courses such as those leading to the Higher National Certificate, particularly to those young people who have no other means of acquiring the basis on which to proceed to technical employment, such courses should, in a planned educational system, be considered as expedients only. They provide neither the time for original, critical, or constructive thought, nor the means of developing latent personal qualities by any form of social and corporate life; and above all it is important to encourage educational methods which develop ability to think independently rather than simply to add to a store of knowledge. That so many young people succeed by the existing methods is a tribute to the individual rather than to the system.

Certain industrial activities, notably those associated with supplies such as water, gas and electricity, are easily recognizable as public services. As time goes on there will be a growing realization that every industry is in fact a national service, although it may be conducted, as at present, by private enterprise. Considered in this light, the importance of employing every means of increasing the efficiency of industry becomes apparent. The conventional system of education is subject to control by national and local educational authorities; but there is no control over the equally important practical side of education for the industrial worker. No national means exist whereby a standard can be set for this phase of education, nor in fact are the resources for training in industry fully utilized.

The *laissez-faire* methods whereby the quality and extent of practical education of industrial personnel depends on a relatively few progressive industrial concerns compare unfavourably with the planned and more efficient methods that are possible in authoritarian countries. Under present conditions this weakness can be remedied only by more complete voluntary co-operation within industry. Such co-operative effort would relieve the burden that now falls upon a few individual firms. An effective way of stimulating this might be the remission of income tax on the money expended on such training. Control could be instituted by restricting the remission to courses approved by a suitably constituted authority.

The establishment in industrial firms of separate 'nursery' workshops in which the fundamentals of handicraft skill and machine operations are taught concurrently with the appropriate workshop instruction will become more widespread. A few schemes of this type are already in operation in private firms and in a number of Government establishments in Great Britain, while the method has been extensively developed in Germany and to a lesser extent in other countries.

The result of introducing manual training at early age, such as exists in the educational syste in the U.S.S.R., will be watched with much intere In contrast to this, with the raising of the scho leaving age, the tendency in Great Britain will for young people to enter industry for practic training at progressively increasing ages. T may involve a more intensive period of practic training, but the difficulties of this should be offset the greater maturity of the trainees concerned, whi the longer period of general education will ensu

An educational problem that is already acu and will be even more so in the future is the supp of suitable teaching staff for the universities a technical institutions. Formerly much of t scientific and technical development relating industry came from the universities. Due larg to the establishment of large-scale research industrial concerns and to the great expansion their technical staffs, the initiative in progress h passed to industry, and many scientific work who previously found their vocations in acade life are now attracted to scientific and techni employment in industry. The result is that in th faculties in which the work has a technologi bearing, there is a great shortage of person available for teaching, so that the time is opportu for the technical institutions and universities consider a long-term policy as regards selecti and training those who will eventually beco the academic leaders.

The practical industrial side of this training of paramount importance. In this connexi co-operation should be arranged with industry provide a suitable range of practical experien without the permanent absorption of the person so trained. Industry has already shown willingness to co-operate with education in t respect by providing short 'refresher' courses those in academic employment who have lit opportunity of maintaining close contact w industrial developments. The technical knowled and experience of eminent technologists in indust might well be utilized more completely than present by co-opting such men to the professor staffs of universities and technical colleges, a thus augmenting, for special courses, the existi teaching facilities. New technical processes n arise so rapidly from scientific discoveries a become so promptly established in industry th the text-books used for teaching purposes c never be completely up to date. The introducti of post-advanced courses in the Lancashire ar appears to be the correct solution to this proble These courses, which comprise short series lectures on specific technical subjects, are giv mostly by experts in industry and are conduct on a basis of exposition and discussion.

The greater availability of technical scholarships id fellowships might well serve as a means of tracting suitable personnel to industrial employent. The extension of fellowship facilities vailable for those who seek experience abroad extremely valuable, particularly if these are warded to men who have already had sufficient xperience to know definitely in what particular irections they wish to supplement their existing nowledge. In the past, many educational pportunities of this type have not been used to the st advantage due to the immaturity of those ceiving the awards, who have not had sufficient perience to appreciate fully that educational and dustrial methods can never be transferred wholly om one country to another because social and onomic conditions differ. Some industrial ganizations have established research fellowips, whereby university staffs can spend ne in industrial research organizations, which ovides experience of inestimable value to e fellowship holder on his return to ademic life.

As yet there is no clearly defined and assured th by which a youth can proceed through the rious stages of education into industrial employent. The national system of education provides e means whereby those of suitable ability can tain education and training up to and including e university or technical college level, but the actical training in industry and an assured start a job is at present fortuitous. In this direction ere is room for greater co-operation by industry ensure the completion of the industrial training and a start in the chosen career. Such an arrangement would give direction and impetus to the various stages of preparation between school or college and industry, would cut down some of the time spent in obtaining what may be unnecessarily detailed technical knowledge, and moreover would relieve both the youth and his parents of a good deal of anxiety.

Greater co-operation than at present exists between education and industry is essential in regard to the syllabuses of workshop and technical studies appropriate to the educational level at which entrance into industry is made. Equally also, co-operation in needed to ensure the adequacy and up-to-date-ness of the laboratory and workshop equipment of the technical institutions and universities.

In this address I have purposely stressed the technical aspects of education for industry, since these to a considerable degree serve also as a basis for the industrial education of the personnel in those branches of industry not directly of a technical character. In so doing I am acutely conscious of the risk that, speaking as an industrialist, I may convey the impression that industry is concerned with the education of its personnel in a narrow sense only. This is far from being the case. All education should be on the most liberal lines, and even to meet the urgent needs of industry no technical specialization should be permitted which excludes the possibility of time being devoted to broadening the mind and equipping the individual to play his part most worthily in the community in which he is placed.

GAS PRODUCERS FOR MOTOR-CARS

THE appearance on a road in the London district of an omnibus with a trailer carrying gas-producing apparatus to provide gas as fuel r its engine is a spectacular event which marks important stage in mechanical propulsion in reat Britain. Although the method is by no eans new, its adoption, even if only on an perimental scale, by a responsible authority on e of its public services, raises it from the category the practically neglected to a position as one the recognized possible alternatives to the use liquid fuel. The trailer is not an essential part the apparatus, and as soon as practical details ve been settled by experience it will be possible embody the gas producer in the vehicle so as to nstitute a self-contained unit; but in the case of e existing pattern of omnibuses there is no surus space in which such an apparatus can be placed. In the case of the private car or delivery van, there is usually room for the required size of gas generator and little difficulty need be experienced in mounting it and its accessories quite conveniently.

In the issue of NATURE of May 6, p. 771, some notes were published on a paper read before the Institute of Fuel by Goldman and Clarke Jones entitled "The Modern Portable Gas Producer" (*J. Inst. Fuel*, 12, 63, Feb. 1939). The authors argued in favour of official recognition of portable gas producers as a means of supplying power for motor-vehicles. Now, nearly twelve months later, the argument for recognition is greatly strengthened, for economists have assured us that transport is the life-blood of modern conditions. Yet now transport is greatly restricted and, for lack of petrol, many cars have been laid up indefinitely or their use limited. The possibilities claimed for this new method of power production, therefore, deserve fuller examination, and, as the fuel is home-produced, those who require a greater degree of use of their cars can consider its adoption. In our earlier article, the process of gasification was described and readers may now wish to have information regarding the British-made apparatus referred to in the paper.

This plant has been successfully mounted on private cars of medium power, on transport and other vehicles, and is so designed as to require no special skill on the part of the driver. A supply of fuel is dropped into a hopper placed above the generator, where a moderate fire is maintained and a gas of high calorific value produced. The gas is cooled by the air going to the generator, to which some steam is also supplied in order to keep the temperature below the ash fusion point, thus eliminating a possible source of trouble. On its way to the engine the gas is passed through a cleaner to remove dust. Photographs reproduced in the paper show the complete apparatus as fitted to a Humber car, a Bedford lorry, and to a tractor hauling a plough, and in each case the addition has been effected without inconvenience or unsightliness. The first lighting of the fire—a matter of no great difficulty—takes ten or twelve minutes, and it does not require to be relit afresh each day. The hopper is charged occasionally with fuel, and this can be done without stopping th engine.

Suitable fuels, such as anthracite or one of th low-temperature cokes—for example, coalite- although abundant, are certainly not so con veniently obtainable as was petrol in ordinar times. This difficulty would be overcome, but i any event users could easily store ample suppli if the authorities granted permission. As regar operating costs, the claim is made that the advan tage lies with the gas producer. On the basis the prices of a year ago, the total operating cos for a 1½-ton vehicle making a weekly round 600 miles would be £11 10s. per week when petr is used and £9 17s. in the case of the gas produce It may therefore be seen that the system practicable and not necessarily expensive.

Official approval of a form of gas produc was conveyed by an announcement made by th Secretary of Mines in the House of Commons la week. He said that the Government, recognizi that in time of war it is clearly in the nation interest to make the best possible use of hom produced substitutes for imported oil, had son time ago set up a committee to consider th problems of such gas producers. As a result, n only has the use of producer gas been sanctione but concessions have also been made to ensure th users do not suffer disadvantage in making th change-over.

OBITUARIES

Prof. A. A. J. de 'Sigmond

It is with great regret that we record the death of Prof. Alexius A. J. de 'Sigmond, professor of agricultural chemistry and technology and soil science in the Royal Hungarian Palatine-Joseph University of Technical and Economic Sciences of Budapest, and formerly director of the Royal Hungarian Institute of Chemistry and Central Experimental Station at Budapest. Coming of an old aristocratic Transylvanian family, he found himself at the end of the War of 1914–18 compelled to choose between his work which lay in Hungary or his estates which were in the country ceded to Rumania. He decided for his work.

To English men of science de 'Sigmond was best known through his investigations on the alkali soils in Hungary, which he described in publications of the Imperial Bureau of Soil Science and the University of California Press. Although there were certain special features about these soils, he had carried out his researches on broad lines, which made the results particularly interesting and helpful to those engaged on soil improvement, reclamation, and similar problems in many other parts of the world, especially the semi-arid regions. His other important bran of study was soil classification, which he dealt wi at length in his book on soil science ; this was writte in Hungarian, but in somewhat abbreviated form was translated into English by Dr. Yolland und the title "The Principles of Soil Science". H classification had the double merit of being comprehensive and based on the chemical compositic of the soil : it was not intended to be final, but satisfactorily filled a number of gaps in other system It has not been universally adopted, nor indeed ha any as yet ; but it represents a distinct addition knowledge on a very difficult and important subjec

Prof. 'Sigmond was a regular attendant at meetin of the International Society of Soil Science, of whic he was an honorary member, and he was always a we come guest in any international group by reason of h wide linguistic abilities and broad sympathies. H was a man of great personal charm and artistic taste he was very fond of music ; and altogether a goo type of the cultured aristocracy of central Euro now unhappily fast disappearing, to the great loss our civilization.

E. J. Russell.

Dr. J. D. Comrie

DR. JOHN DIXON COMRIE, a well-known Edinburgh hysician and medical historian, whose death took lace on October 2, was born on February 28, 1875, he son of Dr. J. D. Comrie. He was educated at eorge Watson's Academy and the University of dinburgh, where he qualified M.B. with first-class onours in 1899, becoming F.R.C.P. (Edin.) in 1906 nd M.D. in 1911. After holding resident appointents at the Edinburgh and Glasgow Infirmaries, e attended post-graduate courses in Berlin and ienna, and was clinical assistant at the National ospital, Queen Square, London, before settling in ractice at Edinburgh, where he successively became athologist, assistant physician and full physician to e Royal Infirmary as well as consulting physician the Deaconess Hospital and the Princess Margaret ose Hospital for Crippled Children, Fairmilehead, dinburgh. During the War of 1914–18 he was onsulting physician to the North Russian Expedionary Force, with the rank of Lieutenant-Colonel, A.M.C.

Dr. Comrie's literary output was considerable. In ddition to his principal work entitled "The History f Scottish Medicine", of which the first edition ppeared in 1927, and the second, enlarged to two olumes, in 1932, he contributed many articles on edico-historical subjects to the *British Medical ournal*, *Edinburgh Medical Journal*, *Archiv für eschichte der Medizin* and the *Proceedings of the nternational Society of the History of Medicine*, at e congresses of which he was a well-known figure. n recognition of his valuable work on medical history e was appointed reader in the history of medicine the University of Edinburgh, honorary fellow of e Italian Society of the History of Medical Science, nd president of the Section of the History of edicine at the meetings of the British Medical ssociation at Edinburgh in 1927 and Winnipeg in 930.

In addition to his original work and his consulting ractice, Dr. Comrie was frequently engaged in an ditorial capacity, being editor of the Edinburgh eries of Medical Text-books, the selected works of . Sydenham, Black's "Medical Dictionary", and nce 1938 of the *Edinburgh Medical Journal*. His nfailing courtesy and kindness endeared him to all ho knew him and particularly his co-workers, by hom he was elected vice-president of the Royal ollege of Physicians of Edinburgh, chairman of the cottish Committee of the British Medical Association, nd president of the Royal Medical Society of dinburgh.

J. D. ROLLESTON.

Dr. Walther Horn

THE death of Dr. Walther Horn on July 10 last n his sixty-eighth year removes a familiar personality from the world of entomology. Although ssentially a worker in taxonomy who held very efinite views on its principles, his interests covered wider field, and he worked for the good of entomology s a whole.

A very regular attendant and contributor at international congresses, Horn became personally known to a wide circle of European and American entomologists. For nearly fifty years he was a student of the Coleoptera, becoming the world authority on the family Cicindelidæ. A few years before the War of 1914–18 he became director of the newly founded Deutsches Entomologisches National-Museum in Dahlem, and devoted great energy in bringing it up to its present status and efficiency. The Museum suffered a severe setback by the advent of the War. Horn was called up for military service and, in this period, he exercised his original profession of a doctor. During the supervening period of inflation, the funds of his Museum dwindled away, and it was only by his untiring courage that things were kept together. By soliciting small sums from his friends in other lands, and by taking advantage of favourable monetary changes, he gradually acquired the means of saving his Museum from ruin. In 1921 its character underwent change and its name was altered to that of the Deutsches Entomologisches Institut, with affiliation to the Kaiser-Wilhelm Gesellschaft in Berlin. Its primary function became bibliographical rather than the maintenance of collections.

At the time of his death, Horn, in collaboration with Dr. Hans Sachtleben, edited three periodicals which were extensively used as a medium for procuring current literature for the Institute by way of exchange. During 1935–37 the publication of Horn's "Entomologische Sammlungen" was a notable effort wherein he recorded the history of all scientifically important insect collections from the time of Linnæus onwards.

Horn's singleness of purpose, coupled with wide travel, linguistic ability and cordiality towards men of all nations, made him many friends. He was able to free himself from some of the binding force of national limitations and, thereby, played a part in promoting international amity among co-workers that will be hard to replace.

A. D. IMMS.

WE regret to announce the following deaths:

Dr. Arthur P. Beddard, chairman of the Pharmacopœia Commission, formerly lecturer in medicine in Guy's Hospital, London.

Prof. R. A. Craig, professor of veterinary science in Purdue University, an authority on the diseases of pigs, on October 12, aged sixty-seven years.

Mr. J. A. Fulton, director of the Mackay School of Mines of the University of Nevada, on October 9, aged sixty-one years.

Prof. H. O. Knight, professor of anatomy in the University of Texas, an authority on the anatomy of the hand and foot, on October 5, aged fifty-eight years.

Dr. R. A. Sampson, F.R.S., astronomer-royal for Scotland during 1910–37, formerly professor of mathematics and astronomy in the University of Durham, on November 7, aged seventy-three years.

NOBEL LAUREATES

Prof. R. Kuhn

Prof. Richard Kuhn, who has been awarded the Nobel prize for chemistry for 1938, is Viennese by birth and a pupil of Willstätter. He has been head of the Department of Chemistry of the Kaiser-Wilhelm Institut für Medizinische Forschung in Heidelberg since the Institute was opened in 1930, and, after the death of von Krehl, was made director of the Institute in 1937. Kuhn's work does not consist of one single great achievement, although he has made important contributions to many problems in organic and biochemistry. His early work was concerned with enzymes and with stereochemical problems. He has done important work on the polyenes, of the general formula $C_6H_5(CH = CH)_n C_6H_5$, which he was able to synthesize up to $n = 15$. It was thus possible to gain information on the behaviour of long chains of conjugated double bonds, which are also of interest in other fields of work such as photographic sensitizers.

Kuhn has also worked out the synthesis of a new class of chemical compounds, the cumulenes. This work led up to a synthesis of vitamin A, which was preceded by investigations on the constitution of carotene. He recognized at about the same time as O. Warburg that the prosthetic group of a yellow ferment which is responsible for the degradation of sugar phosphoric acid esters is present in vitamin B_2. With the synthesis of lactiflavine-5′-phosphoric acid, he achieved the preparation of the active group of an enzyme. Through the application of boric acid in the condensation with alloxan, he was able to increase the yield up to about 90 per cent of the theoretical value. His most recent work is concerned with the chemical nature of sex substances necessary for the copulation of gametes of various algæ. Specific carotinoids, such as crocin and *cis*- and *trans*-crocetin-dimethylester, are essential for the mobility of the Protozoa under anærobic conditions and for the process of copulation. Prof. Kuhn is well known in Great Britain, and he delivered the sixth Pedler Lecture of the Chemical Society in 1938, when he discussed the synthesis of polyenes.

Prof. A. Butenandt

Prof. Adolf Butenandt, who shares this year's Nobel prize for chemistry with Prof. L. Ruzicka, is well known in Great Britain. For a number of years Prof. Butenandt held the position of *Privat Dozent* in the Department of Chemistry of the University of Gottingen under Prof. A. Windaus. There can be little doubt that his association with this laboratory, the work of which had been devoted to the elucidation of the structure of the sterols for so many years, played an important part in his success in determining the constitution of œstrone. It was while he was at Göttingen that Aschheim and Zondek made their classical discovery of the presence in the urine pregnancy of large quantities of œstrogenic materia It was found to be in a purer state and more subje to processes of purification than when extracted fro the ovaries or follicular fluid. The large-scale commercial collection of this material in Germa rendered available in 1928 quantities of startin material. To Butenandt fell the task of elucidatin the structure, and in 1929 he succeeded in obtainin the compound in a crystalline form.

The announcement was made simultaneously wit that of the independent discovery of a crystallin material by Doisy in the United States. Marrian Great Britain had also obtained a crystalline substance, but it was found later to be of a differen constitution from the crystals of Butenandt a Doisy. The work of Butenandt on the seleniu treatment of œstrone resulted in the demonstratio of the presence of the phenanthrene ring system, an a classical paper on this was communicated to meeting of the Chemical Society held in London March 1933. Later Butenandt worked on the constitution of the male sex hormone. He isolate androsterone in the crystalline form and proved i constitution, and his work on progesterone and oth derivatives of the sterols forms the background this important development in chemistry. He le Gottingen to take the chair at Danzig, and was f a few years professor of chemistry in that Universit Some two years ago he was appointed director the Kaiser-Wilhelm Institut of Biochemistry Berlin, which position he now holds. Many of ou readers will remember the three lectures Pro Butenandt delivered at the London School of Hygien and Tropical Medicine in 1936, lectures which we noted for their clarity of style and for their excellen delivery in faultless English.

Prof. L. Ruzicka

Prof. L. Ruzicka, professor of chemistry in th Federal Technical Highschool of Zurich, has a lon record of brilliant investigations in the field of pu organic chemistry. Without doubt, however, th present award is mainly on account of his developmen of the degradation synthesis of hormones from sterol It will be remembered that the workers at Göttinge devoted many years to the elucidation of the structur of the side-chain of the sterols, it being well know that these could be removed by appropriate chemic treatment. The recognition of the structure of progesterone, testosterone, corticosterone and othe highly active hormones of the steroid group le organic chemists to attempt their synthesis. Th formidable nature of this task will readily be appreciated, since not only is the cyclopentenophenanthrene system, with double bonds, polar groups an so on, an extremely difficult object for syntheti iok, but also there is an almost infinite number of eo-chemical isomers due to the presence of lohexane rings. It occurred to Ruzicka that the ; system of the sterols might provide the basis for synthesis of hormones, and he therefore chose a ol with a suitable stereo-chemical configuration the ring system and removed the side chain by dation. This provided a most important basis for synthesis of the hormones, and by suitable nipulation of double bonds, conversion of hydroxyl ups to keto groups, and so on, it was possible to duce from a neutral sterol such as cholesterol the hly potent hormone testosterone. It can be said t the recognition of this principle has solved the blem of hormone production, quite apart from its at theoretical interest. Prof. Ruzicka has been a quent visitor to Great Britain; his addresses are ed for their clarity and for their wit.

f. E. O. Lawrence

HE announcement of the award of the Nobel ze for physics for 1939 to Prof. E. O. Lawrence, fessor of physics in the University of California, Berkeley, will be received by physicists ywhere with approbation. Lawrence's early arches were concerned with photo-electric cts but, in 1930, he became interested in possibilities of using the method of resonance eleration in order to obtain positive ions of very h energies, by means of a number of consecutive elerations through relatively low differences of ential. The method of linear resonance accelera- was pushed to its practical limit in Lawrence's oratory when, in 1934, mercury ions were obtained ing energies equivalent to accelerations through otential difference of nearly three million volts, g, however, applied potential differences having eak value of only 79,000 volts. The limitations of method of linear resonance acceleration in its lication to the acceleration of ions of small mic mass had, however, been recognized by vrence in 1930, in which year he proposed a modition of the method for such ions. This consisted in elerating the ions back and forth between two i-cylindrical hollow conductors, the paths of the ions being rendered circular by means of an intense magnetic field. Thus was conceived the magnetic resonance accelerator, or cyclotron as it is now more generally called.

At that time, it was somewhat generally considered that the practical difficulties involved in the cyclotron were of a magnitude likely to preclude the translation of this conception into terms of practical physics. All the greater then, was the tribute to be paid to the experimental genius of Lawrence when, little more than a year later, he announced the success of the method in obtaining light ions of high energy. His success was acclaimed on both sides of the Atlantic, by the awards of the Comstock Prize of the National Academy of Sciences in 1937 and, in the following year, of the Hughes Medal of the Royal Society, the latter being given for "the most important instrument of physical research since the C. T. R. Wilson expansion chamber". Later, however, Lawrence's interest turned rather towards the vast field of physiological research to which the cyclotron, with its prolific output of radioactive indicators, had opened up a new approach. Important results in nuclear physics continued to pour from the Radiation Laboratory at Berkeley, but at the same time a new side was being developed, and the physiological effects of neutrons and the metabolism of phosphorus and iron, and of like elements which could be obtained in a radioactive form, were being exhaustively studied. Not to Lawrence's laboratory alone was this work confined, his generosity providing for scientific workers in many places in America and in Europe as much radioactive material as they could conveniently use. Lawrence is not only a respected director of a research laboratory but, above all, a valued friend of those who have worked with him.

The 1939 Nobel Prize for literature has been awarded to N. Frans E. Sillanpää, the Finnish novelist. His novels are based chiefly on the peasant life of Finland. The Nobel Prize for Physiology and Medicine for 1938 was awarded to Prof. C. Heymans, and that for 1939 to Prof. G. Domagk (Nature, November 4, p. 777).

NEWS AND VIEWS

al Medals of the Royal Society

His Majesty the King has been graciously ased to approve the recommendations made by Council of the Royal Society for the award of two Royal Medals for the current year as follows: f. P. A. M. Dirac, F.R.S., Lucasian professor of hematics in the University of Cambridge, for the ling part he has taken in the development of the quantum mechanics; Prof. D. Keilin, F.R.S., ok professor of biology and director of the Molteno itute in the University of Cambridge, for his contributions to biochemistry and entomology, in particular for his demonstration of the part played by cytochrome in the oxidation reduction mechanisms of the living cell, and for his studies of the higher Diptera.

Centenary Celebrations in New Zealand

In December 1642, Europeans first discovered New Zealand, although they mistook its general character. A century and a half later their mistake was rectified by Captain Cook. His reports attracted traders and whalers, but lawlessness, arising from "the absence of necessary laws and institutions", led, a hundred years ago, to bringing the islands under the sovereignty of the Queen of England. It is the centenary of this event which New Zealand began to celebrate last week when a great exhibition was opened at Wellington. It is fitting in a new country that prominence should be given to the natural resources of the country, forests, farm lands, and minerals, and to the means which have led to their exploitation, of which the development of methods of transport has been pre-eminent. Two thirds of New Zealand's land is now 'occupied', for the most part not by great landowners but by persons holding less than 320 acres. It is these European settlers who have developed the resources of their country in such a way as to minimize the disadvantages of isolation from the great consuming centres of the world. Happily the economic exploitation of the country has not been accompanied by a disappearance of the native people, for the sixty thousand Maoris live in friendly co-operation with the Europeans and enjoy full social and political equality. This successful experiment in State-building will be worthily celebrated in New Zealand throughout the coming year, and it must be a matter of regret that the war, which has, once again, brought out the loyalty of the Dominion, should have prevented more active participation in this event by citizens from other parts of the British Commonwealth.

Politics and Academic Qualifications in Germany

RESTRICTIONS on academic freedom in Germany, already sufficiently stringent, are to cut more deeply still into the roots of intellectual development. According to the Berlin correspondent of a Copenhagen newspaper, quoted in *The Times* of November 13, the German censorship will see in future all scientific works written for doctors' degrees. This, it is said, is intended to guard against the introduction of theories offending against Nazi doctrines in politics, law, literature, and the population policy. In view of the distorted interpretation of certain scientific and historical facts which alone is acceptable officially in Germany to-day, it might be thought that any further bar to research or freedom of thought would scarcely be necessary to render any approach to originality innocuous. In order, however, to ensure that orthodoxy, or at least what is regarded as such, shall prevail over any attempt at a scientific and dispassionate examination of fact, which might lead to conclusions at odds with officially approved conclusions, decision as to the fate of any given thesis will not rest with an academic body, which at least might be expected to bring a trained and instructed intelligence to the examination of the bearing of an argument and the value of its evidence, but with the censorship. No thesis will even be submitted for scientific examination until it has passed the censor. Regimentation thus strikes at the very root of intellectual development and scientific training. These must no longer be concerned with the search for truth in the investigation of the facts of Na
and history in both the broad and narrower se
but only with the fanatical application of a selec
theory dictated by political prejudice.

Horrocks's Observation of the Transit of Venus

THREE hundred years ago on Sunday, Noven
24 (O.S.), 1639, the young Lancashire curate Jere
Horrocks, and his friend William Crabtree, the
at Hoole, near Preston, and the other at Brough
near Manchester, observed the transit of Ve
across the sun's disk, and thus, as Robert Grant s
"did two young men cultivating astronomy toge
in a state of almost complete seclusion in one of
northern counties of England enjoy the privileg
witnessing a phenomenon which human eyes
never before beheld and which no one was desti
again to see until more than a hundred years
passed away". At Broughton the sky had been o
cast most of the day, but fortunately cleared jus
time for Crabtree to see the transit. At Ho
Horrocks had watched from sunrise until his du
called him to church. At 3.15 p.m., when again f
he resumed his observations, when, as he wrote, '
most gratifying spectacle! the object of so m
earnest wishes, I perceived a new spot of unu
magnitude, and of perfectly round form, that
just wholly entered upon the left limb of the sun

was for the time completely forgotten, but his ma

t, with others, had been preserved and was nately published. Nearly two centuries passed re any memorial was raised to him whom Herschel d "the pride and boast of British astronomy". 1826, however, the Preston astronomer and urer Moses Holden (1777–1864) devoted the eeds of a lecture to the erection of a tablet to rocks in St. Michael's Church, Toxteth, Liverpool; 859 a memorial chapel and window were added Hoole Church; and after the transit of 1874 a ement was set on foot which resulted in the ing within the monument to Conduitt, Newton's hew, in Westminster Abbey, of a scroll recalling great achievement of Horrocks in 1639.

ust Kundt (1839–1894)

November 18, the centenary occurs of the inguished German physicist August Adolph ard Eberhard Kundt, the successor of Helmholtz erlin. Born at Schwerin, Mecklenburg, he studied eipzig under Hankel, Bruhns and Neumann, and Berlin under Encke and Förster, first devoting self to astronomy. Entering the laboratory of nus, in 1864 he graduated with a thesis on polarization of light. He became a *Privat ent* in Berlin in 1867 and then was successively essor of physics at Zurich Federal Technical hschool (1868), at Würzburg (1870), and at sburg (1872), where he took a prominent in the organization of the new university; this he became rector in 1877. Finally, in 3, he was chosen to succeed Helmholtz in the r of experimental physics and as director of the sical Institute at Berlin. He died at Israelsdorf Lübeck on May 21, 1894, a few months before nholtz. His original researches were mainly in domains of light and sound. By an ingenious hod he was able to determine the velocity of d in various gases. In light, he made inquiries the problems of anomalous dispersion by liquids vapours and by very thin films of metal. 'Kundt's nomenon' is the rotation observed, under the ence of magnetic force, of the plane of polariza- in certain vapours and gases. For his experi- ts on dispersion by metal films he made no fewer 2,000 prisms prepared by electrolytic deposition n platinized glass.

Georges Dieulafoy (1839–1911)

ROF. GEORGES DIEULAFOY, a celebrated Paris sician, was born on November 18, 1839, at louse, where his uncle, Paul Dieulafoy, was pro- or of clinical surgery in the medical faculty and ced him to become a doctor. After acting as his e's house surgeon for two years, he went to Paris omplete his education and spent seven years as ital resident under Trousseau, Velpeau, Denon- ers, Jaccoud, Potain, Axenfeld and Tardieu. He lified in 1869 with a thesis on sudden death in oid fever. In 1872 he became an assistant pro- or (*agrégé*) with a thesis on contagion, and the wing year published a medico-chirurgical treatise he diagnosis and treatment of morbid fluids in which he described the aspirator to which his name has been given. In 1880 appeared the first edition of his famous "Pathologie de médecine interne", which in the course of thirty-one years went through sixteen editions and was translated into English, Italian, Spanish, Russian, Polish and Greek. Six years later he was appointed to the chair of internal pathology at the Necker Hospital, where he remained until 1896, when he succeeded Germain Sée at the Hôtel Dieu as professor of clinical medicine; he held that office until his retirement in 1909. During this period he published a number of clinical lectures in six volumes under the title of "Clinique médicale de l'Hôtel Dieu de Paris". In 1910 he was elected president of the Academy of Medicine, of which he had been a member since 1879. His death took place on August 16, 1911, at the age of seventy-two.

The Newcomen Society

THE annual meeting of the Newcomen Society was held on November 8, when Col. C. E. Davies, secretary of the American Society of Mechanical Engineers, was elected president for the ensuing year. Col. Davies for many years acted as corresponding honorary secretary in the United States for the Society. The annual report referred to a further large increase in membership, the total number of members on October 1, 1939, being 1,252. Twenty-five papers were contributed during the year, while in England a summer meeting was held in Suffolk and in the United States a pilgrimage was held in Alabama. For the information of members a *Newcomen Quarterly Bulletin* is now published. The finances of the Society continue to remain in a satisfactory state and the issue of a fifth *Extra Publication* is under consideration. Though for the time the monthly meetings have been suspended, papers are being sent in for the *Transactions*. At the close of the business, the retiring president, Mr. W. A. Young, read his presidential address on "Thomas Newcomen—Ironmonger: the Contemporary Background", and Dr. T. E. Lones read "A Précis of Metallum Martis and an Analysis of Dud Dudley's Alleged Invention".

Statistics of London

THE latest volume of "London Statistics," that for 1936–38 (London: P. S. King and Son, Ltd., 15*s*. 6*d*.) raises once more in an acute and realistic form some of the most vital and interesting questions in social science and economics and in practical statesmanship that we of the present generation have to face. Among them not the least significant are those concerned with population movements to and from the London area and within that area. The population of this Greater London increased during 1937 by 80,000, and numbered 8,655,000 before evacuation, as compared with 7,000,000 for New York. This huge total is about double that of the administrative county over which the L.C.C., has partial control and from which there has been continuous migration since 1901. In that year the population of the administrative county was 4,536,267, but it has steadily declined, so that in 1938 it was 4,062,800. This has involved among other things difficult readjustments in educational facilities, especially elementary schools; for the decrease in elementary school children from 900,000 in 1915 to 543,000 in 1937 is very much greater proportionately than that in the total population. In this connexion it is interesting to note that, of the 50,000 children leaving elementary schools in 1937, 89 boys and 127 girls were described as of "super-normal" mental condition.

The subject chosen in this volume for special analysis is libraries. In the year ended March 31, 1938, 40,116,733 books were issued to borrowers from public libraries in Greater London, and 20,175,088 from libraries maintained by local authorities in extra-London. In addition there were 2,078,559 issued from public libraries in extra-London under county council control. In the administrative county alone, issues of books have risen from 14,512,112 in 1928 to 19,941,654 in 1938, the number per registered borrower increasing from 29·3 to 31·1. For some reason or other, Woolwich heads the boroughs in respect of reading—as measured by use of public libraries—whilst St. Pancras is at the bottom of the list. Readers have 2,431,832 books from which to choose, and they borrow three novels for every non-fiction work.

Recent Comets

An I.A.U. telegram from Copenhagen announces that Comet Faye has been discovered by Jeffers at Harvard on November 3 at 4h. 1m. U.T. Its position is given as R.A. 20h. 13m. 28·3s., S.Dec. 10° 18′ 15″, and it is described as diffuse with central condensation. In the "Handbook of the British Astronomical Association", 1939, the elements and ephemeris of this comet have been computed by Messrs. W. P. Henderson and P. J. Harris, who applied the perturbations of Jupiter and Saturn. Perihelion passage is given as April 23, 1940, but it will be apparently half a day later. A comet was discovered by Frien at Harvard on November 4 at 13h. 30m. Its position is given as R.A. 16h. 52·9m., N. Dec. 34° 03′. The daily motion is +7m. 30s. in R.A. and −10′ in Dec. It is described as diffuse without central condensation or nucleus. Nothing is stated about its magnitude.

Engineers' Study Group on Economics

An emergency programme to meet the difficulties occasioned by the war has been issued by the Engineers' Study Group on Economics. Consideration of the problems which followed the War of 1914–18 has led to the view that, while the first effort must be directed towards winning the present war, attention must be given in good time to plans for reconstruction, so that practical proposals may be ready when required. The Group has accordingly resolved to make a special study of reconstruction, dealing particularly with such problems as demobilization, industrial change-over, agricultural chan international trade, paying for the war, etc. Th interested are asked to communicate with the Gr at 35, Gordon Square, London, W.C.1.

Announcements

The annual Huxley Memorial Lecture of Royal Anthropological Institute will be delivered November 28, at 2.30 p.m., at 21 Bedford Squa W.C.1, on "Charity and the Struggle for Existenc by Dr. R. R. Marett.

The Tilden Lecture of the Chemical Society be delivered by Dr. L. E. Sutton on December at 2.30 p.m. in the Society's rooms. The title of lecture will be "The Present State of Vale Theory".

A paper on the "Penetration of Rays through Skin and Radiant Energy for the Treatment Wounds" will be read by Sir Leonard Hill, at Royal Society of Arts, on November 22 at 2.30 Applications for tickets should be made to Secretary, Royal Society of Arts, John Str Adelphi, W.C.2.

The following have been elected officers for 1 of the Mineralogical Society: *President*, Mr. Art Russell; *Vice-Presidents*, Prof. C. E. Tilley, Dr. Campbell Smith; *Treasurer*, Mr. F. N. Ashcro *General Secretary*, Dr. G. F. Claringbull; *Fore Secretary*, Sir Thomas H. Holland; *Editor of Journal*, Dr. L. J. Spencer.

The following appointments and promotions h recently been made in the Colonial Service: C. Johnston, chemist, Department of Science, Barbad F. H. Ormerod, agricultural superintendent, G Coast; V. D. Van Someren, zoologist, Cent Veterinary Research Institute, Kenya; H. Waters, director of agriculture, Kenya, director agriculture, Gold Coast.

Mr. G. M. Harvey, deputy electrical inspecto mines, has been appointed electrical inspector mines, with effect from November 1, in succession Mr. J. A. B. Horsley. Mr. Horsley is undertak special duties for the Mines Department during war, more particularly in connexion with the org ization of the electrical supplies required for working of mines and quarries. He will also compl so far as possible, the work in connexion with revision of the existing code of safety regulati for coal mines.

The Geological Society of London announces t the eighteenth session of the International Geolog Congress, which was to have been held in Lon during July 31–August 8, 1940, is postponed definitely.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 869.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

estigation of Cosmic Ray Showers of Atmospheric Origin, using Two Cloud Chambers

JSING two simultaneously operated cloud chambers, have investigated the occurrence of large cosmic showers originating high in the atmosphere[1], and transition behaviour of these showers in absorbing terial. The cloud chambers were 28 cm. in diameter h an illuminated depth of 4 cm. (chamber I) and m. (chamber II) respectively. The counters used select showers and so to operate both chambers re all situated around chamber I, there being none und chamber II. The whole apparatus was uated beneath a light roof.

In the first experiments, chamber II was placed at rizontal distances of 5½ m. and 19 m. from chamber and observations over a period of 250 hours were de at each separation. The frequency with which wers selected by the counter array at chamber I tended to the distant chamber II is shown in ble 1. The third and fourth columns give the rate which showers reaching the stated particle density *both* chambers were observed. Portions of a single wer are thus frequently to be found over a distance 5½ m., but to a much smaller degree over a tance of 19 m.

BLE 1. CHAMBERS SEPARATED 5½ M. AND 19 M. HORIZONTALLY

hower density Vo. of particles per 100 cm.²)	Chamber I (rate per hr.)	Chambers I and II simultaneously (rate per hr.)	
		5½ m apart	19 m. apart
> 1	0·39	0·069	0·025
> 3	0·177	0·024	0
> 6	0·082	0·012	0
>10	0·049	0·004	0
>20	0·020	0	0

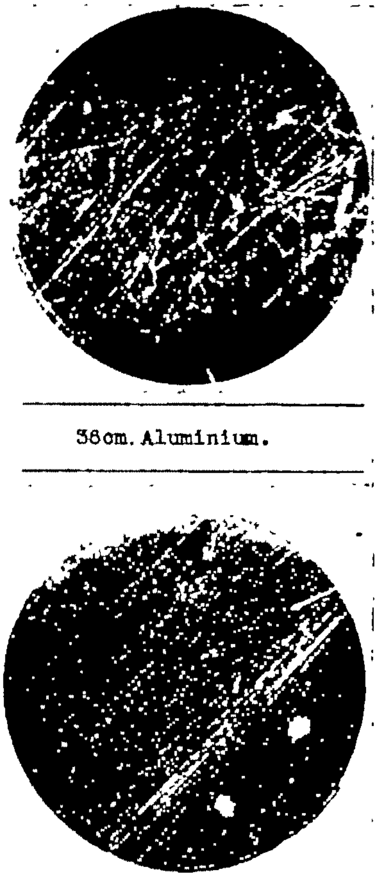
BLE 2. CHAMBER II 120 CM. VERTICALLY ABOVE CHAMBER I

terial between chambers—(i) 36 cm aluminium, (ii) 3 cm. lead. ning time of experiment—(i) 278 hr., (ii) 182 hr.

Particles in lower chamber (I)	Number of photographs			
	Aluminium Total	Aluminium 5 or more tracks in top chamber	Lead Total	Lead 5 or more tracks in top chamber
> 2	143	12	131	11
> 5	85	10	75	9
> 10	41	5	40	6
> 20	12	3	19	3
> 40	2	1	4	1
>100	1	1	1	1

Particles in lower chamber (I)	Percentage of showers in lower chamber associated with 5 or more tracks in top chamber	
	Aluminium	Lead
> 2	8 per cent	8 per cent
> 5	12 ,,	12 ,,
> 10	12 ,,	15 ,,
> 20	25 ,,	16 ,,
> 40	50 ,,	25 ,,
>100	100 ,,	100 ,,

In a second series of experiments, chamber II was placed vertically above chamber I at a distance of 120 cm. Absorbing layers of (i) aluminium (36 cm.) and (ii) lead (3 cm.) were placed immediately above the lower chamber (I), and the relation between atmospheric showers detected in chamber II and the shower phenomena in chamber I was investigated. Table 2 shows the extent to which showers of a given size below the absorber are the result of entrant showers with a certain minimum particle density. For both aluminium and lead, the largest showers result from fairly dense groups of particles entering at the top of the absorber. The average multiplication taking place for atmospheric showers in these thicknesses of material is small (about twice), and so we may conclude that the dense parts of showers have almost reached equilibrium.



A DENSE SHOWER UNDER 36 CM. ALUMINIUM WHICH HAS DEVELOPED FROM A LARGE ATMOSPHERIC SHOWER. THE SEPARATION OF THE TWO CLOUD CHAMBERS IS MORE THAN 1 METRE

Experiments by Nie[2] have been interpreted[3] as evidence for the occurrence of large showers in light materials by an explosive process. We find, however, that both in lead and in aluminium the large showers are the product of only a slight multiplication of pre-existing shower groups. The relative frequency of such showers in lead and aluminium will depend largely on the size distribution and energy spectrum of the incident showers. Little is yet known of these factors, but it is clear from the small average multiplication involved, and from the form of the cascade spectrum in air, that large showers will be relatively much more frequent in the light elements than is indicated by the cascade theory applied to a single entrant particle.

The photograph shows a portion of a large shower below 36 cm. aluminium derived from a large atmospheric shower above the absorbing layer. We estimate that the complete shower contains at least 40,000 particles, and so has a lower limit of energy of 10^{15} e-volts.

Evaporation of Mist Particles and its Bearing on Air Sterilization

During the determination of particle size distribution in various germicidal aerosols, a qualitative correlation was noticed between the biological activity and the persistence of the droplets in the field of the ultra-microscope. The instrument was therefore adapted for the determination of evaporation rates; the disappearance of a selected particle was followed by successive measurements of its fall under gravity, its position being restored after each by a screw which displaced the cell contents upwards. Provisions were also made to follow the particle throughout its wanderings in the horizontal plane. It was then possible to watch a single particle for an indefinite period limited only by its complete disappearance or by physical fatigue in the observer.

A number of phenolic germicides have been examined, in solution both in polyhydric alcohols and non-hygroscopic solvents, such as water and benzyl benzoate.

For the most part, droplets of the binary mixtures examined behave like pure substances in giving a straight-line relation between velocity of fall and time[1,2,3], and therefore between surface area and time, over the greater part of their lives. For example, resorcinol-water mixtures appear to evaporate at a constant rate $\left(\frac{ds}{dt} = \frac{\delta \text{ surface area}}{\delta \text{ age}} = \text{const.}\right)$ which is independent of the concentration and also of the initial particle size over a range 5–50 per cent resorcinol, 0·5–2·5 μ radius. But it can scarcely be taken that such mixtures evaporate at constant composition irrespective of what this is, and, in fact, improved technique has shown that it is not necessary to assume this; in many cases it has been possible to observe a very rapid initial evaporation during which an unknown amount of the solvent is removed, and even with such a high boiling solvent as ben benzoate, this phase is complete in about ten secon when it contains as much as ten per cent of a sol of volatility similar to its own. Generally, the cha in slope of the evaporation curve is so large and sharp that there is nothing indefinite in the divis into stages. The second stage in the evaporat follows the straight line law already mentio $\left(\frac{ds}{dt} = \text{const.}\right)$, and when the particle has beco quite small, there may or may not be a slowing according to the volatility of the solute or presence of impurity. (But there are many anoma in behaviour at this stage; for example, 5 per c glycerol in water (weight in weight) particles evapor completely according to the straight-line law down a radius not greater than 0·05 μ.)

As a result of the initial stage in the evaporati it is not generally possible to estimate the composit of particles when they are under observation, a with volatile solvents it may be remotely differ from that of the parent solution. Ternary mixtu behave in a more complicated way, and by obser tions over a range of initial concentration and droplet size, it is sometimes possible to ded qualitatively the changes in concentration on evapo tion of mixtures of this type. Thus particles resorcinol-glycerol-water mixtures having radii than 1 μ after passing the initial stage begin to l more resorcinol than water, and this continues do to a very small size.

It is found that solutions of phenols in a relativ inactive solvent like benzyl benzoate have a n persistence which is anti-parallel with the volati of the solutes, whereas with hydroxylic solvents t is not always the case, and the anomalies are down to chemical association between the substan present.

Bacteriological experiments have been carried by workers in the biological section of th laboratories on the solutions which we have examin and we are grateful for permission to quote th results.

It was evident from the start that the germici activity of a mist is far more dependent upon volatility of its particles than upon their Ride Walker value. Experiments with highly vola substances, such as phenol, confirmed Bechho contention[4] that their vapours are generally inact against bacteria in suspension; only when the amo of germicide atomized was more than enough saturate the available air space was any kill obtain

Germicidal mixtures of phenol and volatile solv only were roughly divided into three classes.

(*a*) Highly volatile solute: No kill observed unl the air is saturated with respect to the germici Effect dependent on vapour pressure, and not Rideal-Walker value.

(*b*) Volatile solute: A kill occurs over a sh period, after which no further effect is obtained unl the air is saturated. Effect dependent on Ride Walker value to a large extent, since all the must take place in the limited life of the droplets

(*c*) Involatile solute: Almost independent Rideal-Walker value (for example, 50 per c calcium chloride, in water, Rideal-Walker value than 0·05, gives a better result than phenol wh dispersed). The lethal effect extends over a v long period, and some effect is noticeable at enorm dilutions (greater than $2 \cdot 5 \times 10^{10}$ c.c./gm. in case) with a fine mist, if sufficient time is allow se classes correspond roughly to the three stages a typical complete evaporation curve.

t is hoped that a more detailed report of this k will shortly be published.

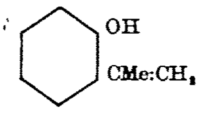
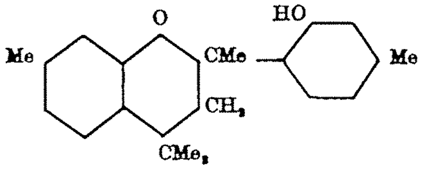
tructure of the Dimeric Forms of *o*-*Iso*propenylphenols

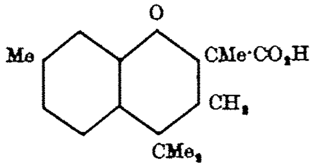
-Hydroxy*iso*propenyl compounds, for example readily polymerize to dimeric forms on long



(I)



(II)



(III)

nding or on treatment with hydrogen chloride[1]. se dimerides can be distilled under diminished ssure and are generally resinous at ordinary temature, but they yield well crystalline *mono*acetyl ivatives, and contain only *one* free hydroxyl up. They exhibit only extremely feeble phenolic perties, are saturated, and depolymerize when tilled under atmospheric pressure. A study of the eric form of *iso*propenyl-*m*-cresol (I)[2] has shown t it yields on vigorous oxidation with potassium manganate a stable carboxylic acid, $C_{13}H_{17}O.CO_2H$, degradation of a *m*-cresyl group to a carboxyl up.

)nly one very improbable structure has been prosed for these dimerides[3]; this contained an olefinic k, and was based on a formula for a condensation duct of *m*-cresol and acetone now known to be orrect[4]. There appears to be only one structure sistent with the above facts and with theoretical uirements. Solely on valency considerations, there fourteen monohydric phenols (excluding those taining a 4-membered ring fused to an aromatic cleus) which could be produced from two molecules an *o*-hydroxy*iso*propenyl compound such as (I) by mutual addition of the two *iso*propenyl groups d ring closure to a saturated cyclic ether. Of these uctures, four may be rejected on stereochemical unds as they contain 7- or 8-membered oxygen gs, and seven because they do not involve the symmetrical addition of the two *iso*propenyl ups, as occurs in the polymerization of styrenes d related compounds; the first step in the densation is regarded as the formation of a $\text{Me}_2.\text{CH}:\overset{(+)}{\text{C}}\text{Me}.$ or less probably $.\text{CMe}_2.\text{CH}_2.\overset{(+)}{\text{C}}(:\text{CH}_2).$ dge between the two aromatic nuclei[5]. Finally, o of the remaining three possibilities may be minated because in ring closure an oxygen atom st unite with the more cationoid of the two saturated carbon atoms (marked with (+)), double bonds being polarized owing to the jacent phenolic group. In the case of either intermediate the ring closure, therefore, leads to 2′-hydroxy-2 : 4 : 4 : 7 : 4′-pentamethylflavane (II), which must represent the dimeride of *iso*propenyl-*m*-cresol.

This structure adequately accounts for the cryptophenolic properties by the presence of the grouping $.\text{C(O.)Me.CH}_2.\text{CMe}_2.$ in the *ortho* position to the hydroxyl; the group $.\text{CMe}_2.\text{CH}_2.\text{CMe}_2$ even para to a phenolic hydroxyl group renders it extremely feebly phenolic. The acid, 2 : 4 : 4 : 7-tetramethylflavane 2-carboxylic acid (III), would not be expected to undergo further ready oxidation.

The structures of the dimeric forms of other *o*-hydroxy*iso*propenyl compounds must be analogous to (II), and there can be little doubt that the dimeric forms of cyclohexenyl-*m*- and *p*-cresols[6] are similarly constituted.

A full account of this work will later be published elsewhere.

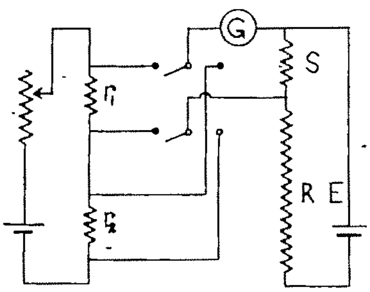
Comparing Resistances of Four-Terminal Resistors

In a letter in Nature of September 30, Mr. Arvon Glynne describes an elegant and simple method for the comparison of four-terminal resistors. In it, as he points out, two of the 'potential' leads have to carry a small current. I would like to direct attention to another method, almost as economical in apparatus, in which no current passes in any of these leads. Resistors of about 1/1000 ohm can be compared in this way with an accuracy of one part per thousand, using apparatus ordinarily available in a laboratory. The principle will be evident from the accompanying diagram.

A low-resistance storage cell *E* supplies current to the circuit *R*, *S*; and *R* is adjusted so as to obtain zero deflection of the galvanometer *G*, first with the resistor r_1 and then with r_2 in circuit. If good storage cells are used in both circuits, steady balances are



readily obtained. In practice, S is given such a fixed value (which need not be known precisely) that R will be several hundred ohms, or more, for either balance. Under these conditions, the resistance of the cell E will be quite negligible and

$$\frac{r_1}{r_2} = \frac{R_2 + S}{R_1 + S}.$$

This principle has, obviously, other applications; for example, to thermo-couple measurements, in view of the low values possible for the resistances of S and G.

Decomposition of Hydrogen Peroxide by Catalase

In a recent letter[1] Johnson and van Schouwenburg dispute Keilin and Hartree's observation[2] that catalase activity depends on the presence of oxygen. In their reply, Keilin and Hartree[3] point out that the experiments of Johnson and van Schouwenburg are only qualitative and therefore not conclusive.

Soon after the publication of Keilin and Hartree's paper[2], we attempted to repeat their experiments, following all their directions as closely as possible, but with negative results. Our experiments were carried out in Warburg manometers with a purified catalase from red blood cells and with an enzyme from cucumber seeds prepared according to Zeile[4]. To ensure complete absence of oxygen, the manometers were gassed with purified nitrogen until no oxygen could be detected by the ferrous pyrophosphate method in control experiments. No difference was found in the rate of the decomposition of hydrogen peroxide in presence or absence of oxygen. The non-enzymatic decomposition was controlled in experiments with heat-inactivated enzyme and was certainly not larger than in the experiments of Keilin and Hartree.

The successive oxidation and reduction of catalase was first suggested by Haber and Willstätter[5] so long ago as 1931. This theory has been developed by one of us[6] along the lines previously suggested by Haber and Weiss[7]. It is based on a radical chain mechanism: the reduction of the ferric form of catalase is brought about by the anion of hydrogen peroxide (HO_2^-) and the oxidation of the ferrous form by the hydrogen peroxide molecule itself. The decomposition of hydrogen peroxide would therefore proceed with the same velocity in the presence and absence of oxygen, as we have indeed observed.

Although, contrary to Oppenheimer and Stern[8], it cannot be generally assumed that an oxidation by hydrogen peroxide would be faster than an oxidation by molecular oxygen, a re-oxidation of reduced catalase by oxygen only would have the effect that no decomposition of hydrogen peroxide could t place at all. The reason for this is that, unles radical chain mechanism is assumed, all the oxy formed by the reduction of the ferric form of catal must be quantitatively used up again for the oxidation of a stoichiometric amount of the ferr form and the oxygen thereby reduced to hydro peroxide. To avoid this difficulty, Keilin and Hart formulated the oxidation reaction by the follow equation:

$$4Fe^{\cdot\cdot} + 4H^{\cdot} + O_2 = 4Fe^{\cdot\cdot\cdot} + 2H_2O,$$

thereby assuming the reduction of oxygen to wa without the intermediate formation of hydro peroxide. This is contrary to accepted theories autoxidation and would appear impossible on basis of the kinetic theory if only for the reason t it implies collisions of a very high order.

Further, on the basis of Keilin and Hartr theory, one would expect the reaction, if carried in nitrogen, to show the characteristic curve of autocatalytic process owing to the increasing forr tion of oxygen. This is, however, not corrobora by the figures of Keilin and Hartree.

Conclusions as to the behaviour of catalase deri by analogy from spectroscopic observations on called 'azide- or hydroxylamine-catalase' cannot accepted as strong evidence for the problem un discussion.

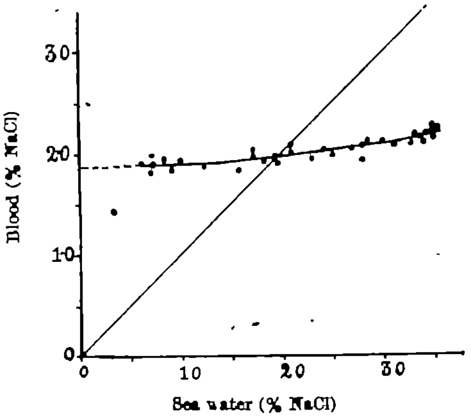
Osmotic Behaviour of *Palæmonetes varians* (Lea

Palæmonetes varians var. *microgenitor* is a comm brackish-water inhabitant of northern and weste Europe well known for its ability to live in differ concentrations of sea water. Specimens collect from brackish waters in the vicinity of Plymou (salinity 23–29 ‰) are quite at home in t tanks of the laboratory containing normal sea wa of salinity 34–35 ‰. Estimations of osmo pressure of blood, by Baldes' modification of Hi thermo-electric technique[1,2], from specimens kept different concentrations of sea water, indicate th while this species is hypertonic in sea water of lov dilutions, it is definitely hypotonic in normal water.

The blood of animals that have been in the s water tanks for some months is isotonic with solution of 2·3–2·1 per cent sodium chloride. Hyp tonicity is maintained by the shrimps in dilutions sea water equivalent up to about 2·0 per cent sodi chloride, when the internal and external media observed to be approximately isosmotic (see acco panying graph). In sea water of 1·8–0·6 per c sodium chloride, there is a slight fall in the va



Relation between the osmotic pressure of lood and the external medium of *Palæmonetes varians*.

alues in per cent sodium chloride. Abscissæ, sea ater; ordinates, blood. Straight line indicates here points would fall if blood and medium were isotonic.

blood from 2·0 to about 1·8 per cent, but the blood ays retains a higher osmotic pressure than the ternal medium, and variations are confined to the ove limits. Dilute sea water equivalent to 0·6 per t sodium chloride was approximately the lowest vival limit for the species in mixtures made with mouth tap water.

The homoiosmotic behaviour of the species is clearly licated by the figures given above, the difference tween the highest and lowest values for blood ing only about 0·5 per cent sodium chloride for corresponding difference of 2·9 per cent sodium loride in the external medium. As compared th typical freshwater Crustacea[3,4,5] the blood of *læmonetes* is found to have a much higher osmotic essure. It is all the more interesting because this operty of maintaining hypotonicity in concentrated d hypertonicity in dilute sea water is known only a few euryhaline crabs[6,7,8]. It would seem that is physiological character of *Palæmonetes varians* ll to a great extent explain its peculiar habits and stribution.

Details of experiments will appear elsewhere.

Amylase in Amphioxus

Specimens of *Amphioxus caribbaeum* collected ile working at the Tortugas Laboratory of the rnegie Institution of Washington were examined th respect to the amylase present in the gut. terminations were carried out by the micro- thod of Linderstrøm-Lang and Holter as modified Holter and Doyle[1]. The intestine was divided into three regions, namely, hepatic cæcum, proximal intestine and lower intestine. The gut was split open, washed, and the area of each piece measured. When examined for amylase activity, the relative activities per unit area were found to be: cæcum, 62; proximal intestine, 41; lower intestine, 30.

In a determination of the relation of amylase activity to pH, the region of the junction of intestine, cæcum and pharynx was used. The final reaction mixture was 2 per cent glycerine, $M/50$ Sørensen phosphate buffer, 1 per cent soluble starch and 1 per thousand sodium chloride. The reaction time was 8–12 hours at 32·2° C. Taking the amylase activity at pH 7·0 equal to 100, the relation to pH is as shown in the accompanying table, with an optimum at pH 7·0. The values given are each averages of six determinations.

pH	Relative activity
6·5	75 ± 4
7·0	100
7·5	74 ± 3
8·0	69 ± 1

Cytochrome Oxidase in Tea Fermentation

An endo-enzyme system in tea leaf which could oxidize tea tannins directly was recently reported by Sreerangachar[1]. The enzyme remained bound to the tissue after exhaustive washing with water or phosphates of acetone-dried tea leaf tissue. Attempts to confirm this work in Assam at first proved fruitless. An enzyme preparation made apparently in identically the same way was completely devoid of oxidase activity. Tea tannin was not oxidized and no characteristic colour with the Nadi reagent was observed in the absence of hydrogen peroxide. An orange coloration developed in the fibrous portions of the leaf but this was found to be due to the interaction of the lignins with p-phenylene diamine. The endo-enzyme, however, showed strong peroxidase activity when hydrogen peroxide was added.

Some Ceylon leaf preserved under acetone which was sent to Tocklai still showed strong peroxidase activity, but no catechol oxidase activity could be detected.

On the other hand, it was shown at St. Coombs that the endo-enzyme could oxidize both tea tannins and catechol directly without the addition of hydrogen peroxide.

We believe the failure to confirm Sreerangachar's findings at Tocklai to be due to the higher temperatures prevailing in Assam. When green tea leaf is treated with alcohol at a laboratory temperature of 30° C. a crude enzyme preparation results with little or no oxidase but high peroxidase activity. If special precautions are taken to keep everything as cool as possible during the treatment of the tissue with alcohol, the enzyme preparation can bring about the oxidation of tea tannins and catechol without the addition of hydrogen peroxide. Treatment with alcohol at the higher temperature has obviously inactivated an enzyme which is essential for the direct oxidation of tea tannins.

The lability of this latter enzyme and the firmness of its attachment to the tissue suggests its identity with cytochrome oxidase. If this latter enzyme were present in the leaf, Sreerangachar's preparation would be expected to contain both the enzyme and its substrate. Cytochrome oxidase together with cytochrome can oxidize both catechol and ascorbic acid, although the enzyme alone is completely specific for cytochrome. The peroxidase in the preparation would also utilize the hydrogen peroxide produced during the oxidation of cytochrome for oxidation of its substrates. In these conditions, with hydrogen peroxide already present, addition of more hydrogen peroxide might not accelerate the oxidation, and the enzyme preparation would apparently have no peroxidase activity.

This interpretation would seem to explain our apparently contradictory findings as to the nature of the oxidizing enzymes in tea leaf. Sreerangachar's finding that tea tannin can be oxidized directly by an enzyme preparation obtained from tea leaf does not necessarily establish the presence of a tannin or catechol oxidase in the system. The claim put forward by one of us[2] that ascorbic acid oxidation is the primary stage in the fermentation process is also withdrawn. The direct oxidation of ascorbic acid by tea leaf tissue finds an adequate explanation in terms of the above theory. Other evidence has also been found against the existence of ascorbic acid oxidase in tea leaf, and these findings together with a fuller investigation of the cytochrome oxidase will be published elsewhere at a later date.

Role of Manganese in the Biological Synthesis of Ascorbic Acid

In continuation of my previous work[1], it has been found that the guinea pig liver also can synthesize ascorbic acid from the sugar precursors both *in vitro* and *in vivo*. The concentration of manganese necessary for the synthesis is much higher than that required in the case of rat liver.

In vitro			*In vivo*		
% Mn in R.-L.	Sugar	Mgm. ascorbic acid per gm. liver	Exp.	Mgm. ascorbic acid per gm. liver	Remarks
0 10	Mannose	0 20	1 c.c. N S. intraperitoneally	0·21	Killed after five hours.
0 01	Mannose	0·14	40 mgm. galactose in 0·04% Mn intraperitoneally (1 c.c.)	0·25	
0 10	Galactose	0·17	0·5 c.c. N.S.	0 24	Young growing guinea pigs killed after 8 hours
0 01	Galactose	0 13	25 mgm. mannose in 0·5 c.c of 0 04% Mn	0 30	
Nil	Nil	0 13			

The hypothesis is advanced that the inability the guinea pig and man to synthesize their requi ment of ascorbic acid is due to the lack or insufficier of manganese in their tissues. The active oxidat or dehydrogenating mechanism is made up of m ganese and the dehydrogenase, manganese acting the capacity of a coenzyme.

Further investigation in support of the hypoth is in progress. Details will be published elsewhere

Polyploids are More Variable than their Origi Diploids

Studying the modification of a large number experimentally produced polyploid plants of vari species and families (Solanaceæ, Gramineæ, Co positæ, etc.) within the single plants and in the po ploid lines in respect to the modification of th diploid forms, when the plants grew in equal envir mental conditions, I found the following regularit Cell dimensions showed in the majority of the ca studied a greater modification in the tetraploid th in the diploid plants. Cell dimensions of the exp mentally produced octoploids were more varia than the cell dimensions of tetraploid and dipl forms. The numbers of chloroplasts per pair stomatal cells were more variable in the tetraplo than in the diploids and much more variable in octoploids than in the tetraploids and diploi Counting, for example, the chloroplasts[1] in 100 pa of stomatal cells of each form of *Nicotiana ala* diploid, tetraploid and octoploid, the following val for the standard deviations were respectively foun $\sigma_{2n} = 1{\cdot}81$, $\sigma_{4n} = 4{\cdot}76$, and $\sigma_{8n} = 7{\cdot}03$. (It found that polyploidy does not affect the size of chloroplasts[1,2]. It also does not significantly aff the variability of the chloroplast diameter.) T modification of the cell dimensions decreases son what gradually in the subsequent polyploid gene tions, that is, it decreases with the increase of t polyploid generations. But in the cases stud tetraploids still had more variable cell dimensio in the fifth generation than the corresponding diploi

It was logical to expect that a greater modificati of the cell sizes and of the numbers of the chlo plasts (assimilatory organs) of the polyploid for should condition a greater modification of the pla size as well as of all the dimensions of the pla organs. Our measurements showed that this is tr in the majority of the cases. Plant size, leaf dime sions, and flower dimensions were in the majori of the cases much more variable in the tetraploi than in the diploids. The organ dimensions of t octoploids were more variable than those of t diploids and tetraploids.

It was also logical to expect that a greater modific tion of the cell dimensions of the octoploid a tetraploid plants should lead to more freque developmental anomalies. It was found that tet ploid plants formed a greater percentage of abnorm flowers and leaves than the diploids. The tenden was noted for tetraploids originating from spec with large chromosome numbers to form a somewh greater percentage of abnormal flowers than t tetraploids originating from species with sm chromosome numbers. Experimentally produc octoploids formed a much greater percentage normal flowers and leaves than the tetraploids and loids. Modifications of the organ dimensions and ger percentages of anomalies of the tetraploids ve the tendency somewhat to decrease with the rease of the polyploid generations, but, in the ajority of the cases both were still greater in the raploids than in the diploids.

F_1 species hybrids of distantly related species had, the majority of the cases, more variable cell and gan dimensions than the parental species; they o formed abnormal leaves and flowers more often. ll dimensions of the majority of the amphidiploids at were studied were also more variable than those F_1 species hybrids from which they were produced. ey also formed abnormal organs more frequently. amphidiploid, however, did not show greater difications of the cell and organ dimensions and l not form many more abnormal flowers and leaves an the F_1 hybrid from which it originated, but the ter was a cross product of distantly related species, owing very great modifications of cell and organ nensions and forming a very large percentage of normal flowers and leaves. The numbers of seeds per flower by the auto- and allo-polyploid plants re much more variable than the numbers of the ds set by their ancestral forms. A series of allo-typloid species, studied recently, showed greater difications of cell and organ dimensions than the loid species of the same genus. But there were o allopolyploid species that did not show greater difications of the cell and organ dimensions in mparison with the diploid species of the same genus. e increase of the modifiabilities of polyploids and certain F_1 species hybrids (the products of distantly ated species) are of great significance from the olutionary and plant breeding (agricultural) points view, because they are closely connected with the sticity and adaptability of the plants, playing at e same time an important role in the geographical tributions of the plant organisms.

A series of allopolyploids and F_1 hybrids have, in addition to the increased modification, increased frequency of abnormal mitosis[2], and more often produced somatic mutations[3,4] than the parental species. Both allopolyploids and autopolyploids that propagate sexually often give rise to new hereditary variations as a result of abnormal meiosis and crossings-over between partially homologous chromosomes[5,6]. Extensive studies in the genuses Triticum and Nicotiana showed that in the majority of the cases polyploids are characterized by a much greater polymorphism than diploids. Our data are in close agreement with those obtained by N. I. Vavilov upon the same problem but from another point of view.

Sir Frank Dyson

I HAVE been planning to write the life of my father, the late Sir Frank Dyson (formerly Astronomer Royal), but owing to war work have had to postpone the task for the present. I am, however, anxious to collect letters and other material before these are destroyed.

May I appeal to those who knew my father for any letters they may have of his, or for any reminiscences they may care to give me. I should very much value the personal reminiscences of his scientific friends.

I shall naturally take the greatest care of all papers sent to me, and I undertake to return them within a few days.

MARGARET WILSON.

The Chimes,
Radford Rise, Stafford.

Points from Foregoing Letters

OBSERVATIONS are recorded by A. C. B. Lovell and G. Wilson of the frequency with which cosmic ray owers from the atmosphere affected two cloud ambers operated simultaneously and arranged in fferent ways. From the average multiplication served when lead or aluminium is interposed be-een the chambers, they conclude that large showers ll be relatively more frequent in light elements than indicated by the cascade theory applied to a single trant particle.

The evaporation of droplets in mists of phenolic rmicide solutions has been studied by S. R. Finn d E. O. Powell by means of the ultra-microscope. e results, correlated with the biological findings, show at three rough classes of bactericidal behaviour are stinguishable according to the volatility of the solute.

From a study of the dimeric forms of o-hydroxy-opropenyl compounds, W. Baker and D. M. Besly nclude that they must be derivatives of flavane. his structure satisfactorily explains their properties.

J. J. Dowling describes a method for the com-arison of small resistances using ordinary laboratory paratus.

J. Weiss and H. Weil-Malherbe state that further antitative work on the action of catalase has shown that catalase activity does not depend on the presence of oxygen. This is in agreement with the theory proposed recently and based on the earlier discussion by Haber and Willstätter. It was not possible to corroborate Keilin and Hartree's results, whose theoretical views are also criticized.

N. K. Panikkar finds that *Palaemonetes varians* is hypotonic in normal and hypertonic in dilute sea water. The osmotic pressure of its blood ranges from 1·8 to 2·3 per cent NaCl for a corresponding range of 0·6–3·5 per cent NaCl in external medium, isotonicity being at about 2·0 per cent. The homoiosmotic behaviour of the species is of interest in view of its habits and distribution.

In examining the intestine of Amphioxus for amylase activity, W. L. Doyle found that the greatest activity per unit area was in the caecum and the least in the lower intestine. The relation of *p*H to amylase activity was also studied and showed an optimum at *p*H 7.

J. Lamb and E. H. Houghton produce evidence that the oxidase responsible for the oxidation of ascorbic acid in the tea leaf may be identified with cytochrome oxidase, and that it is unlikely that an ascorbic acid oxidase is present.

RESEARCH ITEMS

Ghost Figures of Santa Cruz

The wooden figures from Santa Cruz, which represent the ghost or soul of a person who has been successful during his life and has gained prestige, are figured and described by Joyce Gillett, of the Cranmore Ethnographical Museum, Chislehurst, in *Man* of October 1939. These wooden figures are made after death and erected in the house of the deceased, when a feast is given. After the feast, the figure remains in the house standing in a corner. Very often skulls are seen standing around the figure, and these are said to be the skulls of past owners and keepers. Each figure has one keeper, and often gifts of tau and conch shells are placed before it. The figures are made, and regarded with esteem, not on account of an unwillingness to forget the dead, but because of a fear that unless something tangible is made in the likeness of a man who was lucky, that which was for the good of the people during his lifetime may be lost for ever. But if such an image is made, it is believed that the maker has captured for all time the gift of being lucky which was bestowed on the deceased, and this can now be transferred into the body of any living person—usually a member of the family or a relative—where it will continue to function. One example, now in the Cranmore Museum, was found in a disused house, not a ghost house, suspended from a height of five feet, and encased in a conical bird-cage of wood, the whole being covered with mats and tapa cloth, which appeared to have been smoked over a fire. On unwrapping, a very carefully decorated male form was found, in the nose and ears of which were pendants of pearl shell; pearl shell pendants hung on the hair, which was wrapped in tapa cloth and dressed in the shape of a cone, and protruded at the back of the neck. Biceps, wrists, knees, and ankles are circled with fibres on which are pendants and adornments of shell or seeds, while around the waist was a loin-cloth and a girdle of currency. The whole figure was dusted with turmeric.

The Quintuplets

J. W. MacArthur and A. R. Dafoe (*J. Hered.*, 30, 359–364; 1939), continuing their analyses of the Dionne quintuplets examine their growth up to their fifth birthday. The quintuplets were unlike at birth but have become, as is usual in monozygotic twins, more similar than fraternals. The variability in weights was greatest at times when growth was retarded—birth—weaning—before removal of tonsils. The maximal differences fell from 45·1 per cent at birth to 7·2 per cent at five years. Similarly height differences fell from 4·5 per cent at one year to 1·1 per cent at five years. The rates of growth of the quintuplets are neither equal, nor proportional to birth weight, but are regulative as with regenerating parts which tend to reach their potential dimensions under equal environmental conditions.

Inheritance of Disease-Resistance

L. T. Webster (*J. Hered.*, 30, 365–370; 1939) has analysed the reactions of mouse populations to mouse typhoid and encephalitis virus. Progenies of parents who died within 10 days of infection wi mouse typhoid were more susceptible than th from surviving parents. Selection and inbreedi from susceptible and resistant parents retained th characteristics, while hybrids between highly resiste and highly susceptible mice showed a monofactor F_2 segregation for resistance to both typhoid and cephalitis virus. Resistance is dominant in both cas The outbreak of epidemics in genetically hete geneous populations is discussed. Epidemics caused in hitherto uninfected populations by introduction and spread of a highly virulent, stable infecting agent. In an infected population agent remains stable but the resistance of the po lation is reduced by inadequate diet or other caus The dosage in the population therefore increas Those individuals which are innately suscept become infected first. The epidemic curve refle this genetical difference in susceptibility.

Genetic Differences in Wild *Drosophila pseudoobscura*

Th. Dobzhansky (*Proc. Nat. Acad. Sci.*, 25, 31 314; 1939), continuing his studies on geneti differences in wild populations, shows that samp of different populations of *Drosophila pseudoobsc* caught in southern Texas show structural differen in the third chromosome similar to those previou found in California. Further, although some popu tions were only 1¼ miles apart, these appeared be different in constitution and to be distinct breedi units.

Mouth-parts of the Female Anopheles Mosquito

In *Parasitology* (31, 212–242; 1939), G. G. Rob son gives an account of the piecing mechanism us by the female mosquito during feeding. It appe that the observation made by Vogel in 1920 that t labral canal is closed ventrally by the opposed edg of the labral groove is confirmed. The hypopharyn on the other hand, plays no part in the vent closure of the food channel, except at its base. T use of the term 'labrum-epipharynx' is dispensed w in favour of the simple designation of 'labrum Snodgrass, it is pointed out, disagrees with t homology of the labella with labial palpi on t ground that the lobes of the labium have usua each a single muscle inserted directly upon it, where the palpi have antagonistic muscles. It is sho that in Anopheles the labella have these antagonis muscles as in typical palpi, and the homology consequently upheld. During feeding, penetration the skin of the victim is made by the labrum a the wide terminal blades of the mandibles act as cap to the entrance of the labral canal and serve f its protection during penetration. The function the maxillæ is to help in the efficient and smoo penetration of the host's skin.

North American Bees of the Genus Osmia

Under this title the Entomological Society Washington presents the first volume of what expected to be a series of memoirs. Written Grace A. Sandhouse, it is a cloth-bound publicati of 167 pages and was issued in August 1939. Bees genus Osmia are essentially denizens of the earctic and nearctic regions, few being found where, and they are entirely wanting from the ctic and Ethiopian regions. Of approximately names, which have been proposed for species of oia in the nearctic region, about 120 become onyms and 30 are referred to other genera, thus ing 130 names now in the genus. The issuing of memoir was made possible from accumulated rest on a monetary bequest of the late Frederick ab which was supplemented by a donation by E. A. Schwarz. Inquiries regarding the sale of publication should be addressed to the Corresnding Secretary of the Entomological Society of shington, care of the Bureau of Entomology and nt Quarantine, Washington, D.C.

astrous Earthquakes, January–June 1938

. P. Rothé has discussed the earthquakes felt man during the first six months of 1938 (*Revue r l'étude des calamités*, 2, No. 7, 230–241; July–gust 1939). The five most disastrous shocks were e of February 5 in Columbia, April 19 in Asia or, May 3 at Iguala in Mexico, May 19 at Célèbes, d June 11 in Belgium. The epicentral region of Columbian earthquake, which was felt as far as ama, corresponded roughly with the great 'graben' he Cauca Valley, the depth of focus being 150 km. siderable damage was done and people were killed d injured at Armenia, Calarca, Pereira, Manizalles, nzazu, Villa Maria, Riosucio, Aguadas, Medellin d Amaga. Probably the greatest shock of the iod was the one with epicentre in the vilayet of sehir in Turkey, where ten villages were comtely destroyed. Altogether about 756 houses were troyed and 800–1,000 people were killed or gravely ured. The epicentre of the earthquake of May 3 been determined at the Observatory of Tacubaya have been near Huilziltepec (Guerrero). This ck resulted in the destruction of much property, deaths of five people and injury to thirty-eight ers. The earthquake of May 19 with epicentre the Straits of Macassar was particularly violent l did great damage at Dongala, where sixty houses re ruined. The earthquake was followed by a sea ve 2–3 m. high which flooded areas 80–100 m. and, doing great damage to dwellings, crops and rchandise and resulting in death and injury several people. According to M. O. Somville, the centre of the Belgian earthquake of June 11 was the centre of the Mons-Brussels-Ghent triangle l its depth of focus 50 km. This shock resulted in deaths of three people and damage to property several millions of francs. Damage to property s at Brussels, Audenarde, Courtrai, Lille, etc., ndows were broken at Anvers, and the shock was t at Paris and at distances up to 300 kilometres m the epicentre.

ocity of Coloured Light

DURING the last twenty years, observations have n made to determine whether light of different ours travelled through interstellar space with the ne velocity. They have in general been based on ervations of the times of the primary minima of light of two wave-lengths of a binary star, genery Algol. Some have led to the conclusion that d light travels faster than blue, others the reverse. e question has been recently examined by J. S. Hall Amherst College Observatory, working at the Sprout Observatory with grants from the American Philosophical Society and Swathmore College (*J. Franklin Inst.*, 228; Oct. 1939). He measured the light of Algol, of wave-lengths 5599 A. and 8060 A. respectively, by a photo-electric photometer and compared them with that of a non-variable star Alpha Persei, making corrections for background illumination, atmospheric extinction and sensitivity of the photometer. He concludes that the minima for the visual and infra-red rays occur at the same time with an uncertainty of 3 minutes. As the light from Algol takes 195 light years, that is, 55×10^6 minutes, to reach the earth, this means that the speeds of the two lights are identical to within 3 parts in 55 millions. This supports the similar conclusion of Russell, Fowler and Borton from the scarcity of matter in interstellar space and the earth's atmosphere.

The Minor Planets of the Hecuba Group

THE above is the title of the Halley Lecture delivered by Prof. A. O. Leuschner on June 16, 1938 (Oxford: Clarendon Press. 3*s*. 6*d*. net). The Hecuba Group comprises about one third of all the known minor planets, and they revolve about the sun with approximately twice the angular daily rate of Jupiter. When very close commensurability exists, for example, if a planet revolves at almost twice the angular daily rate of Jupiter, the determination of the exact motion of the planet becomes complicated. Bohlin's Group Method has been applied to the problem with considerable success, and von Zeipel and also Leuschner and his colleagues have developed the method, tables being published to facilitate the computations. In the "Berkeley Tables", produced by Leuschner, higher order terms have been used than were employed by von Zeipel, and their application to Hygeia and a few other planets confirms their great accuracy. The Rechnen-Institut has recently utilized these tables for the development of the perturbations of the planets of the Hecuba Group, and Dr. Raube has already published the results for Erato and Antiope. There is a considerable amount of detailed examination of particular cases which present various difficulties, and those who are engaged in this highly specialized form of work will find much useful material in Prof. Leuschner's lecture to assist them.

New Mathematical Tables

A SEVEN-PLACE parallel table of $\tan^{-1} x$ in radians and $\log_{10}(1 + x^2)$, computed by Dr. L. J. Comrie, has been added to the "Tracts for Computers" of the Department of Statistics, University College, London. Prepared in the first instance to assist in the fitting of curves of Pearson's Type IV to frequency distributions, the table will obviously assist in any other problem which involves the numerical integration of a rational function with a definite quadratic denominator; that the logarithms are not natural does not imply a complication in practice, for in any application except to a manufactured example a logarithm is sure to be multiplied already by some numerical constant. Second differences are provided for interpolation, and Dr. Comrie's name is a guarantee of absolute accuracy. The printing is excellent, and if we complain that paper wrappers are an inadequate protection, that is because we have no doubt that the tables are going to be subjected to hard wear. The tables are published by the Cambridge University Press, price 3*s*. 9*d*.

COALBURSTING

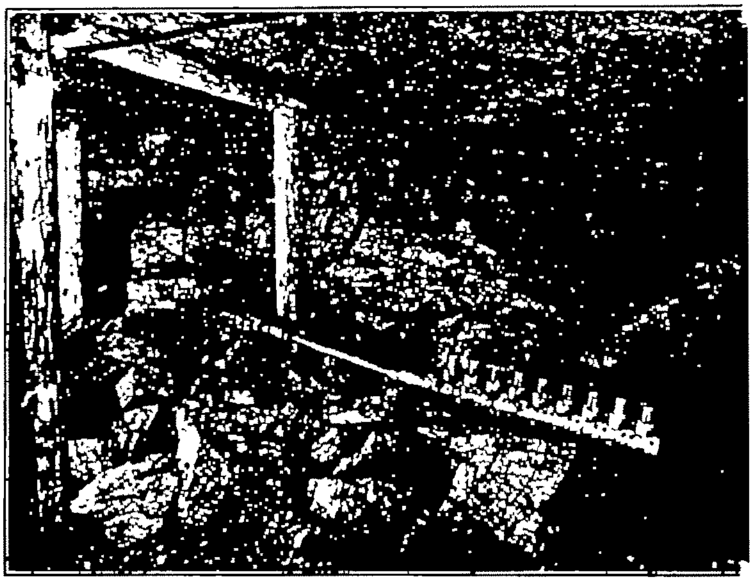

Fig. 2.

Dislodgment of coal completed: note the pistons of the coal burster fully extended and the chunky nature of the coa brought down.

As the coal mines of Great Britain were mechanized, the standard practice became to undercut the coal seam by means of a coalcutting machine and then to bring down the coal by drilling holes in the seam above the cut, inserting charges of 'permitted explosives' and then detonating these. This method of winning coal, however, suffers from grave disadvantages. Every shot that is fired is a potential danger, especially when detonation results in what is technically known as a blown-out shot. Even if no explosion results, the cloud of coal dust produced tends to make the mine atmosphere unpleasant and dangerous. Furthermore, when shots are being fired, the workmen must be withdrawn from the coal face to a place of safety, thus interrupting work. Finally, the shock of the explosion may damage the roof so that the men on returning to the face are confronted with a changed set of conditions which may be very dangerous, especially when the roof is friable. When it is realized that in a single colliery 100,000 shots may be fired per annum, the magnitude of the potential danger is obvious.

Any method which obviates the necessity for firing shots is of interest to the mining community, and furnishes an opportunity for pure science to be of assistance to industry. A great variety of chemical and physical methods of bringing down coal h
been tried during the last fifty years, one of th
being the Tonge hydraulic wedge. The modern 'c
burster' is a development of Tonge's hydraulic we
which has been made possible by the developme
in metallurgical science and engineering practice
relation to the transmission of hydraulic power
high pressure. It entirely elimina
shot-firing and has been used ove
sufficiently long period of time
its usefulness and efficiency to
assessed; several hundred co
bursters are now in use in
British coalfields.

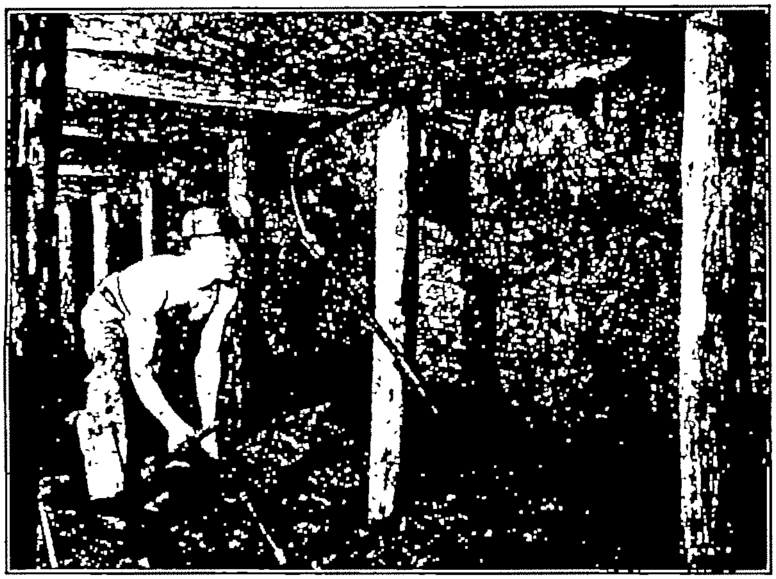

Fig. 1.

Building up pressure in the coal-burster.

In coalbursting, the seam is
dercut as before with a mechani
cutter and holes are bored in
coal above the cut by electric dr
or compressed air drills of the t
bine type. Now, however,
coalburster is placed in the h
instead of a charge of explosi
Briefly, the coalburster consists o
round stainless steel barrel (ab
3 ft. in length and 3 in. in diame
being a common size) chamber
on one or both sides to accomm
date a number of pistons,
plungers, each about 2 in. lo
which can be forced out radia
from the barrel by hydraulic pr
sure. This hydraulic pressure is
veloped by a small hand-pump, co
nected to the burster by a length
armoured hose, a pressure of so

00 lb. to the square inch being developed and com- nicated to the pistons. Since the hole in the coal been drilled as a snug fit for the bar and steel liner ch goes beneath it, the forcing out of the pistons in- ves the disrupting and breaking down of the coal. er the burster has been placed in the hole, the miner ires to the pump some 10–20 ft. away and operates hand pump to generate the pressure required to st down the coal. As a rule, the coal comes down hin two or three minutes of commencing to rate the pump, and several tons of coal are ught down at each operation.

ne advantage of this technique is obvious—there no possible risk of an explosion. Moreover, very le coal dust is produced, so that conditions pre- posing towards an explosion are absent, and, of rse, the mine atmosphere is much pleasanter and lthier for the workmen. Again, round coal of ximum market value is produced and it is not ttered or rendered 'tender' by an explosion; therefore it does not suffer from disintegration in transport. Finally, but not least important, the roof is in general not disturbed. Should any change in conditions take place, however, the fact that the men are present all the time, and not withdrawn as in shot-firing, means that there is a very much better chance of detecting changes in roof conditions.

It is found in practice that the coalburster has very few limitations, that it will operate successfully on all types of coal, hard or soft, in stalls as in widework, and will function well under a variety of conditions. One colliery in Great Britain has for some years now been getting its whole output (8,000 tons per week) by means of coalbursters, shot-firing being completely eliminated. The device must be looked upon as a notable contribution to the safer working of coal mines and to the production of coal of higher market value than has been possible by the use of explosives.

A. Harvey.

SCIENTIFIC AND INDUSTRIAL RESEARCH IN NEW ZEALAND*

HE thirteenth annual report of the Department of Scientific and Industrial Research, New land, which covers the year 1938–39, refers to initiation of a number of new research activities. e of the most important of these is the formation a Timber Protection Research Committee of the ncil to direct and co-ordinate research on the servation of timber from the attacks of wood- ing insects and fungi. The depreciation of build- securities from the attacks of these pests presents erious problem in New Zealand, and the research gramme planned by the committee contemplates rk by the Entomological Division and Plant eases Division of the Plant Research Bureau, uding biological studies of wood-infesting insects, etration tests for wood preservatives, and toxicity ts with insects and fungi, as well as further work the Dominion Laboratory on the analysis of wood servatives and the chemical aspects of penetration ts.

he serious effects of uncontrolled soil erosion have to the establishment of an expert technical com- ttee on soil erosion and land deterioration, to ort on the measures necessary to maintain vegeta- e cover in New Zealand and prevent irreparable mage. The report of this committee is in process publication and indicates that in few cases is the mage beyond repair, although in many areas soil sion has reached a serious state, and a programme handle the problems that are now apparent is lined.

n addition to its intensive studies on cheese rters, the Dairy Research Institute has carried out number of investigations on butter-making, in- ding the oxidation of the fat of butter in cold rage, starters for butter, and the factors affecting rdness of butter. Other work has been concerned th the chemistry of incipient oxidation defects in tter, and the control of mould in dairy products, including the resistance to mould attack offered by different pigments, and the effect of various paint vehicles and driers. The Plant Diseases Division of the Plant Research Bureau has continued its investigations on the control of dry rot in swedes and turnips, the control of club-root, and the use of arsenate, derris and nicotine sprays and dusts for the control of diamond-back moth. Other work of this Division has been concerned with timber preservation and the testing of seed disinfectants; a fourth list of certified sprays has been issued. The Entomological Division has continued its work on the introduction of parasites for the control of the diamond-back moth, on the sheep maggot fly problem, and on timber borers. Animal research at Massey College has been concerned with the application of accurate scientific methods for measuring wool characteristics to the grading of individual stud sheep, and arrangements are being made with the Wool Manufacturers Research Association at Dunedin for the commercial processing of wool with known and accurately measured characteristics.

Fruit research has covered fertilizer, rootstock and pruning experiments on apples, and studies for the chemical control of bronze-beetle and red-mite, physiological studies of internal cork of apples, spraying experiments and the testing of certified sprays. The Fruit Cold Storage Committee has investigated the use of copper-treated wraps for the control of the spread of grey mould in winter cole pears, as well as the effect of fertilizer treatment on the keeping quality of Cox's Orange Pippins and other varieties of apples. Storage trials have been continued with Ballerat and Washington apples. Experimental work on boron in relation to physiological diseases has been directed towards the persistence of boron dressings in soil.

The Tobacco Research Advisory Committee has been concerned with seed-bed experiments, seed germination studies and investigations on mosaic disease. The plant selection work has yielded a natural Italian perennial rye grass cross ecotype,

Thirteenth Annual Report of the Department of Scientific and ustrial Research. Pp. 134. (Wellington, N.Z.: Government nter, 1939.) 2s. 9d.

showing definite promise for short-rotation arable lye, such as occurs in the South Island. Interesting work has been carried out by the Plant Chemistry Laboratory on plant growth-substances and their effect in promoting the rooting of cuttings, and particularly effective results have been obtained with β-indolylbutyric acid.

The report also refers to the work of the Leat and Shoe Research Association, the Wool Ma facturers Research Association, which has contin the study of the raw wool scouring process, to ra research, the activities of the Social Science Resea Bureau and of the Dominion Laboratory and G logical Survey.

THE CRAB NEBULA: A PROBABLE SUPER-NOVA

THE Crab Nebula in Taurus, which has the distinction of being No. 1 in Messier's Catalogue, is of peculiar interest, as is shown by articles published respectively in *L'Astronomie* (August 1939) and in the *Telescope* (September 1939). These articles summarize the results of several technical papers published on this subject during the past few years. It seems likely that the Crab Nebula was first recorded by John Bevis, an English physician, in 1731. It was rediscovered in 1758 by the French astronomer, Charles Messier, and was later the subject of careful scrutiny by Sir William Herschel. It was observed with the great reflector at Parsonstown, Ireland, by Lord Rosse, whose drawing of the nebula, published in 1844, probably suggested its name. It remained, however, for astronomical photography to show, first in 1892 by Isaac Roberts and later by the American astronomers (Keeler, Curtis and Ritchey), its peculiar filamentary structure and afterwards to provide data for measuring its linear rate of expansion of about 0·18″ per annum.

Using this value and the present angular dimensions of the nebula and extrapolating backwards, an interval of about 800 years is obtained for the nebula to expand from a point of origin. A similar time interval (900 years) was obtained by Hubble. Spectra of the Crab Nebula, first obtained in 1913–15 at the Lowell Observatory, showed a bowing of the emission lines, when the slit of the spectrograph crossed the whole extent of the nebula (major axis 6′). Interpreting this feature as a differential Doppler effect due to the approaching nearer side of a shell of gas and the receding further side, Mayall in 1937 derived a velocity of expansion of about 1,300 km./sec. fr Lick spectrograms. Assuming a constant rate expansion, he concluded from the available data t the epoch of the outburst was about A.D. 11 Meanwhile, Lundmark had pointed out that Crab Nebula was near the position of the bri object recorded in Chinese and Japanese annals having been seen for six months in A.D. 1054. 1934, a translation by Y. Iba of the Japanese rec gave the position of the object as near the s ζ Tauri and its brightness as equalling that Jupiter. By combining the apparent linear expans in seconds of arc per annum with the absolute pansion in km /sec., the order of distance was rived as 1,500 parsecs, equivalent to nearly 5, light years. Using this distance and the appar magnitude of Jupiter (− 2·2 m.), the absol magnitude of − 13·1 is obtained for the nova, wh must have been at least one hundred times as bri as an ordinary nova.

In *Contributions* from the Mount Wilson Obser tory No. 600, W. Baade assembles the evidence the existence of two classes of novæ, common no and super-novæ, which differ in luminosity by factor of about 10,000. Typical of the former cl is the nova which appeared in the Andromeda neb in 1885 and reached a maximum apparent vis magnitude of 7·2, equivalent to an absolute mag tude of − 15·0. To this recently recognized cl of super-novæ, so the evidence suggests, the no of 1054 may have belonged, and the expanding sh of gas originating with the cosmic explosion is s visible as the Crab Nebula.

TREATMENT FOR ROT-PROOFING SANDBAG REVETMENTS

SANDBAG revetments exposed to the weather tend to break up, due to rotting of the sandbags, and inquiries have been made about preservatives. Two types of preservative are suitable. They are respectively a creosote or tar distillate, used as a water emulsion, or a solution of an organic copper salt in creosote made up into an emulsion. The former is more widely available than the latter and is suitable for treatment of revetments in position which have already deteriorated by being exposed to the weather for some time. The latter is more potent but is also more expensive, and its use will not generally be justified unless the bags are in good condition and unless it is desirable to take down the whole revetment, treat all the bags and then re-pile them.

The application of the preservatives should confo with the following specification:

(1) A creosote or tar distillate of medium creos type applied as a water emulsion in such a quantity to give on the exposed portion of the bag a coating creosote not less than one fifth of the normal d weight of the fabric exposed. This is given appro mately by a 25 per cent creosote emulsion wh sprayed on the bags to give a thorough coati completely satisfying the absorption of the fibr The creosote should comply with British Standa Specification No. 144/1936, 'Creosote for preservati of timber'.

Any normal emulsifying agent may be used a the following is given as an example of the proc of emulsification.

The following ingredients are used: 65 parts osote and 35 parts water with 1·2 parts oleic acid, 3 parts casein and 0·36 parts sodium hydroxide as emulsifying agent. The agent is dissolved in ter and the two fluids are mixed in a jet similar to at of a cream-making machine. An emulsion pre- red in this way should be stable and can be trans- rted in drums or kegs. Before use it should be uted with water. to a suitable consistency for raying so that the creosote content does not fall low 25 per cent.

(2) An organic copper salt is dissolved in creosote tar distillate of the type indicated in (1) above, e solution then being made up into an emulsion th water, by the use of a special type of emulsifying ent. The copper salt should be one of an organic ty acid of high molecular weight (such as, for ample, copper oleate). The organic copper salt ould be added in the proportion of 16 per cent of e weight of the creosote, and the whole should be ulsified with water. When sprayed on the bags it ould be applied as 20 per cent emulsion. This will ve 0·5–1·0 per cent of metallic copper, estimated the normal weight of the fabric when conditioned der ordinary atmospheric conditions.

Care should be taken to coat thoroughly any ms visible on the face of the pile and to work the ulsion well into the seams. The spraying should done with a paint spray or horticultural spray, d the stirrup-pump recommended for A.R.P. fire otection may be used if no other spray is available. re is needed to avoid fire risk during application when handling creosote in the ordinary way. creosote may cause permanent stains, suitable asures should be taken to protect the surface of ildings against which the bags are placed whilst raying is in progress.

In order to obtain the best possible penetration o the revetment the preservatives should not be plied immediately after a heavy rain. They will far more effective if the pile is given a reasonable e for drying after rain.

It will be desirable to repeat the treatment, and this ould be done at intervals not exceeding three nths.

UNIVERSITY EVENTS

Durham.—The honorary degree of D.C.L. has been nferred on Sir Charles Peers, chief inspector of cient monuments and architect in charge of the rham Castle restoration scheme since 1933. The norary degree of M.Sc. has been conferred on Mr. A. Linge, clerk of works for the scheme.

London.—Owing to the war, and the absence of e University from London, the following honorary grees among others have been conferred *in absentia*: Sc. on Prof. Niels Bohr and Sir Robert Robinson; .Sc. (Economics) on Mr. R. G. Hawtrey and Mr. mon Marks.

Oxford.—R. S. G. Rutherford, Wadham College, s been appointed a research officer in the Institute r Research in Agricultural Economics as from tober 1.

Dr. S. N. Chakravarti, St. Catherine's Society, has en granted the degree of D.Sc. for his work in nthetic organic chemistry.

SCIENCE NEWS A CENTURY AGO

Fecundation and Development of Plants

At a meeting of the Ashmolean Society, at Oxford, on November 19, 1839, Prof. Daubeny explained the new views with respect to the fecundation and the development of plants, which had been brought forward by Brown, Mirbel, Schlieden and other botanists of the day. When Linnæus, he said, had established the doctrine of the sexuality of plants he left to his successors two branches of inquiry in a manner untouched, namely, first, in what precise method do the stamens operate upon the pistils when they cause fecundation to take place; and secondly, to what extent can we trace an analogy between the mode of fecundation and development in the case of flowering plants where sexes exist, and in that of cryptogamous ones, where they are not discoverable. The first of these points had been elucidated by the researches of Brown, A. Brongniart and Ehrenberg, while the analogy subsisting between flowering and cryptogamous plants had been investigated by Mirbel in France and Schlieden in Germany. The former observed new cells originating out of those already existing in the case of Marchantia; while the latter appears to have shown that a process the same in kind takes place within the pollen tubes emitted from flowering plants at the very time they reach the ovary and impregnate it, as well as the cells of the plant in the subsequent stages of its growth. From Schlieden's researches it would seem to follow that the embryo exists in the pollen, and not in the ovary; the office of the latter organ being merely that of furnishing to the young individual a receptacle and nourishment. This, however, was disputed by Mirbel.

Conception of the Steam Hammer

In his "Autobiography", James Nasmyth, when speaking of the iron ship *Great Britain*, which it was at first intended to drive by paddlewheels, said that Mr. Francis Humphries, finding great difficulty in obtaining tenders for the large wrought iron shaft, approached Nasmyth. "In this dilemma," said Nasmyth, "he wrote a letter to me. . . . This letter immediately set me a-thinking. How was it that the existing hammers were incapable of forging a wrought-iron shaft of thirty inches diameter? Simply because of their want of compass, of range and fall, as well as of their want of power of blow. A few moments' rapid thought satisfied me that it was by our rigidly adhering to the old traditional form of a smith's hand hammer—of which the forge and tilt hammer, although driven by water or steam power, were mere enlarged modifications. . . . The obvious remedy was to contrive some method by which a ponderous block of iron should be lifted to a sufficient height above the object on which it was desired to strike a blow and then to let the block fall down upon the forging, guiding it in its descent by such simple means as should give the required precision in the percussion action of the falling mass. . . . I then rapidly sketched out my Steam Hammer, having it all clearly before me in my mind's eye. In little more than half an hour after receiving Mr. Humphries's letter narrating his unlooked-for difficulty, I had the whole contrivance, in all its executant details, before me in a page of my Scheme Book. . . . The date of this first drawing was the 24th November, 1839."

The Fossil Fishes of the Yorkshire Coalfields

On November 20, 1839, the naturalist William Crawford Williamson (1816–95) contributed to the Geological Society a paper "On the Fossil Fishes of the Yorkshire and Lancashire Coal Fields". Within the previous four years the Coal Measures of these counties had assumed a zoological importance which hitherto they had not been supposed to possess. In Lancashire ichthyolites had been lately found to pervade the whole of the series from the Ardwick limestone to the millstone grit, and in Yorkshire they had also been found in abundance. These remains, except in the case of the Ardwick limestone, always occurred in highly bituminous shale and were most abundant where plants were least numerous. The fishes were found chiefly in the roof of the coal, rarely in the seam itself, and not often in its floor. The author made some observations on the manner in which ichthyolites were associated with other fossils in the Coal Measures. At Burdiehouse they occurred in the midst of fresh-water shells and Cypris; at Coalbrook Dale with marine Testacea; at Middleton, near Leeds, with Lingulæ; and at the top of the series in Lancashire and Derbyshire with Mytili and Melaniæ. When he read this paper, Williamson was a medical student; in 1851 he became first professor of natural history, anatomy and physiology at Owens College, Manchester. He was Wollaston medallist in 1890.

Roman Causeway

"Some works for improving the channel of the Scheldt", according to the *Gentleman's Magazine* of November, 1839, "have occasioned several extensive cuttings across the old Roman causeway called La Chaussé de Brabant de Brunehaut, which connects in a straight line the towns of Bavay and Tournay. These cuttings took place on the spot described in the Itinerary of Antoninus as the Pons Scaldis. In the course of the works there have been discovered on various points remains of constructions, and large quantities of material which indicate the site of a town or large village; and it appears that in this locality several bridges have been thrown over the Scheldt. This discovery shows that the point given by antiquaries as Pons Scaldis was not merely a bridge over the Scheldt, but a Roman station which was probably fortified."

Royal Botanic Society

The issue of the *Gentleman's Magazine* of November 1839 contains the following information: "A charter of incorporation has just been granted to this Society, 'for the promotion of botany in all its branches, and its application to medicine, arts, and manufactures, and also for the formation of extensive botanical and ornamental gardens within the vicinity of the metropolis'. The Charter appoints the Duke of Richmond as the first president, Mr. Marjoribanks the first treasurer, and the Duke of Norfolk, the Earl of Albemarle, Mr. Rushbrook, Philip Barnes and James de Carle Sowerby Esqs. the first councillors. The organization is similar to that of other scientific societies, and meetings for the discussion of scientific subjects will be held periodically. The anniversary meeting is assigned by the charter for the first of January. Steps are in active progress for the completion of the gardens in Regent's Park, in which exhibitions will be held in the approaching season."

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned:

Lecturer in the Mining Department—The Principal, Techn College, Sunderland (November 25).

Sub-Librarian of the University of Cape Town—The Secret Office of the High Commissioner for the Union of South Afr Trafalgar Square, W.C.2 (December 31).

SCIENTIFIC AND TECHNICAL LITERATURE AND INFORMATION

HE incidence of hostilities has already brought in its train considerable dislocation he various activities that are concerned with provision of literature and information. In world of science and technology this dislocamay seriously affect the national effort unless implications are rapidly appreciated and ropriate readjustments made. To the dis- ance that, as in the War of 1914–18, resulted n interference with the supply of foreign ature and from the diversion of money and ur into activities apparently more necessary n the provision of information, the present lict has added the distraction caused by air- l precautions. In consequence of these latter, y institutions have ceased their activities, or sferred them to locations relatively remote from tres of storage and distribution of information. re-orientation of scientific and technical inves- tion is essential in war-time. To a certain ex- t research based on careful analysis of previous k must yield place to intensive experimentation oted to the rapid solution of urgent problems, to enhanced productivity along well-estab- ed lines, involving observation and testing er than co-ordination and deduction.

here is still a case to be made out for research the more fundamental type, divorced from siderations of purely war-time expediency, just there is a case strongly supported for the vision of intellectually satisfying literature and

But the present review is more concerned h the provision of literature and information cifically germane to the war demands.

f outstanding importance in this connexion is supply of current scientific and technical odicals, both domestic and foreign. Second only to this factor of supply of literature is that of its distribution for individual consultation in accessible localities. Lastly, there is the problem of adaptation of the literature to meet specific needs, that is, the problem of co-ordinated information or documentation.

As regards the supply of scientific periodicals, there is no reason to anticipate interruption in the receipt of the publications of non-European countries. But there may be delays in receipts, and occasional lacunæ due to enemy action. Probably the only real trouble will be delay, since replacement of any issues actually lost will be fairly simple. In the case of supplies of European periodicals, especially those emanating from Germany, considerable reduction in the normal supplies must be anticipated, and replacements will be difficult, if not impossible. It is important, therefore, that such stocks as are received should be wisely allocated to storage and distribution centres, and that any copies received for purely temporary perusal should be conserved in case of need. A clearing-house for this section of literature is needed at the outset, to which surplus copies can be sent for conservation, and demands for filling gaps submitted. Something on the lines of the Smithsonian Institution service might perhaps serve the purpose.

In regard to distribution, it is obvious that more elasticity will be needed in consequence of the re-distribution of centres of research. Many provincial libraries will have abnormal calls upon them for literature, whereas many London libraries will experience a falling off in demand, especially for consultation on the spot. The necessity for lending will be augmented, and the risk of casual losses in transit enhanced; added to this risk, there will be that of destruction of publications issued, due to enemy action or accident.

From the point of view of increased need for borrowing publications, it is satisfactory to know that the lending service of the Science Library, South Kensington, will be maintained, and augmented to any necessary degree. The situation is being carefully watched, and appropriate steps are to be taken to meet any increase in demand for these widely appreciated facilities. But it must be remembered that this library is situated in a fairly vulnerable area, and alternative supplies ought to be provided in case its own are dislocated. The National Central Library is still functioning as a clearing-house for demands for books on loan, but it relies very largely upon the Science Library for supplies of scientific and technical publications. Probably, in this respect, it is not so much necessary to create alternative central scientific lending libraries as to establish a system of co-ordination among the various provincial libraries, of the university and research types.

A union-catalogue of war-time holdings of important foreign (especially European) periodicals in such libraries as are willing to lend appears to be a necessary first step. This catalogue could very rapidly be compiled, and located at the proposed institution serving as a clearing-house for supplies.

Finally, there remains the problem of supplying information, that is, of documentation; this service naturally comprises the initial one of indexing or abstracting. So far as is known, the normal peace-time British abstracting services are continuing to function, and our workers can rely also upon a steady supply of abstracts, etc., from the United States. But these latter may be delayed and interrupted, and the importance of an acceleration in the tempo of abstracting must be emphasized. A review of the available machinery in Great Britain is obviously needed in the present circumstances. Perhaps, as the sequel, a better co-ordination will be secured and overlapping avoided; what is important, however, is that any gaps should be closed.

On the wider question of documentation, a warning against over-emphasis upon specialization is needed. British research services are rightly proud of their diversity and individuality. But with the threat of war-time economies, and the urgent need for increasing the speed of the survey of available literature on certain problems, there is grave danger of undesirable duplication. Moreover, it has always been a defect of system in Great Britain that undue attention is focu upon outstanding publications, whereas oth are very largely neglected. This criticism app particularly to publications in difficult langua There is no excuse for neglecting such publicati at a time when thousands of refugees, represent many different languages, are living in Gr Britain and anxious to assist in any possible w the national effort.

Finally, the methods now in vogue for rec stituting published scientific and technical reco into forms adapted to easy reference in relat to specific problems need to be improved. It long been obvious that our present methods largely a legacy from the last century, w records were much less numerous and activ less interdependent. Moreover, new techni have been introduced, for example, into business world, that are capable of adapta with great resulting advantage into the fiel scientific documentation. Hitherto their us this field has been hesitating and half-hear and consequently their value has been diminis A co-ordinated, large-scale adoption of mo methods is long overdue, and the present em gency suggests itself as providing the neces inducement, for the reason that now the eff of research workers, technologists and busi *entrepreneurs* are directed to a specific task, canalized in particular channels. Co-operatio endeavour and interchange of information essential if the effort is to be a maximum.

To sum up: a central body is needed im diately to meet the conditions now obtainin respect of the supply and use of current Europ scientific and technical periodicals. Its funct would be to record holdings of such publicati in the various centres of research and libra and to maintain a service of spare issues replacements in the various centres. It would serve as a centre for lending via regional serv outside London, and to co-ordinate informa services and ensure adequate 'coverage' of periodicals selected for attention. Any additi abstracting or digesting, translation or repro tion necessary might also come within its purv Eventually it might be possible to cover European literature in addition, but the estab ment of a central body for the limited pur suggested appears to be an urgent need. La it would act as a repository of information, distribute appropriate extracts, epitomes or c plete dossiers as needed.

THE BIOLOGY OF THE CELL SURFACE

The Biology of the Cell Surface
By Ernest Everett Just. Pp. xi+392. (London: The Technical Press, Ltd., 1939.) 26s. net.

DR. JUST has written an interesting account of his personal views on a group of subjects ncluding fertilization, cell division, and the function of chromosomes. The first part of the book, dealing mainly with the structures, functions, and movements of the ectoplasm (the outer layers of the protoplasm) of marine eggs, contains a large amount of material on which there is fairly general agreement. The following chapter, on water, deals with the movements of water in eggs, and between eggs and their environment. It is stated that when eggs are placed in hypertonic saline, water leaves the egg in discrete droplets, which apparently have to pass through comparaively narrow channels in penetrating the ectoplasm. This extremely interesting observation, if confirmed, would invalidate the majority of the work which has been done on the permeability of marine eggs, in which it is assumed that water leaves the egg by simple diffusion. In the same chapter, Dr. Just betrays some doubt as to the existence of a relatively impermeable membrane at the surface of the cytoplasm. There is to-day no ambiguity on this point; the impedance studies of Cole (*J. Cell. Comp. Physiol.*, 1, 1; 1932; *J. Gen. Physiol.*, 18, 877; 1935) have hown that such typical eggs as those of Arbacia and Hipponoë have a membrane which is mpermeable to ions, while Chambers (*Biol. Bull.*, 69, 331; 1935) has shown by microdissection that this membrane is liquid and fatty in character.

The account of fertilization and parthenogenesis s excellent and perhaps the most interesting part of the book. Dr. Just's objections to Loeb's superficial cytolysis correction' theory of parthenogenesis are justified by adequate experimental evidence; he presents an alternative view (p. 245): "The most important factor in all modes of nitiating development is a dehydration process affecting directly or indirectly the ground subtance" of the cytoplasm. With this statement here may be some measure of agreement, although ultra-violet light, which is an effective parthenogenetic agent with many eggs, and the prick with a needle which will initiate development in a frog egg, can scarcely be considered as dehydrating agents. This rebuttal of Loeb scarcely justifies, however, the following remarks (pp. 238–239):

"The history of biological research furnishes us with other examples which illustrate the shortcomings of such physico-chemical approach in the setting-up of a singly studied property of living matter as synonymous with the whole complex of life-processes. Witness the theories of oxidation, permeability, electrical conductivity, viscosity, and the like. . . . Or take the almost universal fashion in which Hill's work on nerve conduction was accepted. By 'proving' that a nerve conducts without heat-loss this work must lead logically to the conclusion that the nerve fibre is not living, since it gives no evidence of metabolism. Strictly orthodox morphologists have likewise often presented theories of life-processes on the basis of demonstrations that only emphasize anew the capacity of the living thing, though debased, to respond according to its specific and intrinsic irritability. The now perfect collapse of the organizator theory is a case in point."

The first sentence of this paragraph shows that Dr. Just is flogging a horse which is not only dead, but had never lived except in the minds of a few holding extreme views. Such remarks impair a book which is always interesting when dealing with the author's own experimental work, and their rather frequent occurrence may lead many to dismiss it at less than its true value.

Succeeding chapters on cell division and cleavage are of great interest. Much ingenious indirect evidence is quoted to show that cell division may be independent of nuclear division. It is regrettable that the excellent work of E. B. Harvey on parthenogenetic merogeny (*Biol. Bull.*, 71, 101; 1936) is not once mentioned. Mrs. Harvey has shown that non-nucleated egg fragments of a number of species, for example, *Arbacia punctulata*, will develop, after parthenogenetic treatment, in a manner closely similar to that of the normal egg up to the stage of a blastula of about 500 cells. They do not, however, form free-swimming larvæ, and it seems highly probable that development beyond this stage is normally controlled by the nucleus. Thus the possibility of independent division of nuclei and of cytoplasm inferred by Dr. Just has, in fact, been directly observed.

The later chapters, dealing with chromosomes, etc., are almost entirely speculative. Some idea of the direction of these speculations may best be given by quotation:

"As development of the egg progresses [pp. 320-321], the egg potencies are restricted through their withdrawal from the cytoplasm by the chromosomes with each successive cell-division. Thus the cytoplasm forms functional areas. At some time in the history of the eggs' development, the potencies, having been previously taken out and stored by the chromosomes during cleavage and succeeding stages of differentiation, escape into the cytoplasm. The cytoplasm of the fertilized or parthenogenetically developing egg restores them again to the chromosomes."

P. 328: "The active 'factors' for Mendelian characters do not reside in the genes; rather, the genes, by extracting definite materials from the cytoplasm, render possible the reaction of the cytoplasm-located hereditary factors. Only in so far as they take out substance do the genes determine heredity. Thus finally every cell in the mos complex organism has in its nucleus all the poten cies bound except that one which is free in th cytoplasm, and which makes the cell specific."

Dr. Just does a useful service in directin attention to the role of the cytoplasm, but it is t be feared that in his attempts to give importan roles to the cytoplasm, he has abstracted mor from the significance of the nucleus than is pe missible.

J. F. DANIELLI.

PRAGMATICAL LOGIC

Logic
The Theory of Inquiry. By John Dewey. Pp. viii + 546. (London: George Allen and Unwin, Ltd., 1939.) 18*s*. net.

THIS book is the author's fourth on the subject, but only one other, "How We Think", is listed in the English Reference Catalogue. The present work is suited to more advanced students: it is discursive and controversial in manner, and Mr. Dewey's characteristic style will not encourage the puzzled beginner. It views logic—somewhat strenuously—as the study of the methods of solving problems.

Problems are all practical: "How to arrange things to suit us? What would suit us?" Evaluation and actual experiment are necessary for securing final judgment (pp. 160, 179) Final judgment has an actual subject and an ideal predicate (p. 124). Truth is defined by reference to ultimate agreement through certain methods of inquiry (p. 345). No actual judgment is incorrigible (p. 141): inquiry is continuous. Propositions are instruments for reaching judgments: they are defined by reference to symbols (pp. 51, 110). They include two fundamental sorts: existential, which express factual data, and non-existential, which define concepts (pp. 136, 283). The former are generated by the operations of selection-rejection, unifying-discriminating—which are the organic basis of 'is', 'is not', 'and', 'or' (p. 186). No existential proposition is ever universal: general existential (or 'generic') propositions, though expressed by 'all' or 'no', are not A or E propositions, since they assign only *observed* singulars to kinds (p. 380). Genuine universals are all definitive of kinds—that is, they exhibit possible substitutions within one system of symbols (pp. 300, 404). Such syntactical relations, however, are instituted on the basis of past discoveries: so that transformation from one expression to another (deduction) leads t inference, which is existential and probable. chief aim of science is to institute a language tha facilitates inferences. Mathematics is the fre development of syntactical relations—the exhib tion of language as a system (p. 394). Induction—gathering of evidence—proceeds under directio of hypotheses the implications of which ar explored by deduction (p. 427). Universal pro positions are used as causal laws in order to sho the continuity of series of events: causation i not itself an ontological category (p. 458). frequency theory is offered to justify the relianc we place in inductive-deductive methods (p. 470

The inquiry begins as an empirical descriptio of inquiries (a kind of directed behaviour). Th rules of inquiry appear as contracts, demands t be satisfied (pp. 16, 406). The psychology of usin symbols is described as the organic basis logical functions (p. 186). But logic must not onl describe, it must also justify, the methods inquiry. Here I detect an ambiguity: we ma *justify* a given rule by deriving it, according t certain principles, from more fundamental rule Such justification is absolute: by it we distinguis valid arguments from merely persuasive argument It consists in exhibiting all valid procedures one system unified by certain principles of co sistency, identity, etc. This justification is pr vided by formal logic. But what justifies t system itself? Rationalists *justify* (in anoth sense) the laws of thought, by appeal to a 'inerrable faculty'. Pragmatists—rejecting 'supe natural' reason—seek a merely *practical justifica tion* of inquiry. Their typical error is to try justify particular principles without showing the place in one system. This ignores absolute, logist justification altogether; and plainly we cann complete a practical justification of any definitio merely by reference to special interests a situations. For we must justify the rules th vern the inter-relations of terms, that is, the rmal rules and formal signs that bind a system gether. This might be done by showing that nless terms have fixed meanings throughout one gument, the aims of inquiry cannot (causally) e achieved.

A painstaking reader will come to the conclusion at Mr. Dewey is highly successful in avoiding pical pragmatist errors. There are, however, rtain hesitations which will excite the suspicious nd disconcert the unwary. Does Mr. Dewey nfuse formal and nonformal (p. 312), logical and sychological (pp. 106, 186)? Does he confuse the formal dilemma '*A* or *not-A*?' with the nonformal '*A* or *B*?' and so miss the fundamental importance of consistency (p. 346)? Does he understand necessary connexion (pp. 19, 44)? This last question is answered very satisfactorily indeed in Part 3—but doubt may survive until then.

Formalists will find many of their objections met if only they can be persuaded to read 546 pages of wordy and repetitious discourse. Pragmatists and logical positivists will welcome an able and comprehensive account of the views of one of the three or four founders of pragmatism.

KARL BRITTON.

SEISMIC PROSPECTING

ractical Seismology and Seismic Prospecting
y Prof. L. D. Leet. (Century Earth Science
eries.) Pp. x + 430 + 5 plates. (New York and
ondon: D. Appleton-Century Co., Inc., 1938.)
5s. net.

OTH from an academic and a commercial point of view, the exploration of the crust of the arth by explosion waves has assumed considerable nportance in recent years. Of great geological terest, for example, are Prof. Ewing's seismic xploration of the continental shelf of the northastern part of the United States and Dr. Bullard's ecent delineation of the Palæozoic floor of East nglia, whilst on the industrial side seismic prosecting has been employed in the search for oil nd in supplying data required in the construction f highways, bridges and dams. A treatise giving ore than a mere outline of the technique is herefore of considerable interest, especially as ctual surface strata by no means conform to the lealized uniform sheet usually depicted in works n seismology; it is all the more acceptable since is written by a practical seismologist who is qually familiar with the geological, geophysical nd technical aspects of the work.

The book is in five parts, with tables and ppendixes; it has a large number of excellent lustrations and copious references. The kernel f the treatise consists of Part 2 (elasticity and lastic waves), Part 3 (instrumental methods) and art 5 (seismic prospecting). Although the title f the work indicates a twofold purpose, workers n seismological observatories have been adequately atered for already, and the justification—a ufficient one—of the present volume is the dearth f easily accessible information on seismic prospecting.

Part 2 is of great interest. The first chapter (Chapter iii, on elastic constants) describes laboratory methods and gives valuable tables of elastic moduli of a large number of rocks as determined by modern experiments, including also the high-pressure determinations of Bridgman and others Chapter iv, on the propagation of waves in surface strata, is very thorough, and is as clear an account of the subject as could be desired; two- and three-layer structures, with inclined interfaces, are treated, as likewise is Slichter's important work on layers in which wave velocity varies with the depth. Chapter v, on the paths and travel times of earthquake waves, completes Part 2, and is complementary to the two preceding chapters.

Part 3 consists of two long chapters. Instruments (Chapter vi) are given an adequate theoretical treatment, and the theory of the Benioff electromechanical transducer is included. One is disappointed to find so little about the seismographs used in prospecting, although to some extent this is explained by the secrecy maintained (probably needlessly) by commercial geophysical organizations concerning details of their apparatus. Chapter vii, on the instrumental observation of earthquakes, outlines the interpretation of records and summarizes the general conclusions that have been drawn concerning the interior of the earth; some of this work could scarcely be called 'practical seismology', but it is perhaps as well not to insist on too rigorous a distinction.

It is Part 5, to be read in conjunction with Part 2, that makes the most distinctive contribution to seismological literature. A fairly full account is given of the reduction of observations, in particular of the tracing of a salt-dome. Formulæ are developed for dealing with reflexion shooting and for working up the results by the method of least squares; there is also some information on the reading of explosion records. The chapter on special commercial applications includes a table of patents on seismic prospecting taken out in the United States.

The great drawback of this book is its expense. The portion already outlined is just about all that the title of the volume demands, and for the practical student this content, occupying some 250 pages and costing perhaps 15s., would have been admirable. The author, however, wanders over so wide a field that the title is misleading. For example, he opens with a chapter on "Cause of Earthquakes", which is mainly an interesting but irrelevant summary of the geological histor of North America; the long chapter on the distribution of earthquakes might well have bee omitted. There are short chapters on terminolog and the history of seismology, and substantia chapters on the effects of earthquakes, importan earthquakes of history, and the mechanics o earthquake occurrence; all these are interestin enough in their proper setting, but quite out o place in a work of the scope indicated by its titl It would be a real help to the average student wh has little to spend on text-books if this attractivel written and well printed treatise could be re issued without Parts 1 and 4 and at about hal its present price.

R. STONELEY

PROF. STEPHEN TIMOSHENKO

Contributions to the Mechanics of Solids

Dedicated to Stephen Timoshenko by his Friends on the occasion of his Sixtieth Birthday Anniversary. Pp. viii + 277. (New York: The Macmillan Company, 1938.) 22s. net.

EMINENT scientific workers are frequently the recipients of special awards and public or professional honours, but it is rare to find the ceremony of presentation displaying these features that transformed the annual dinner of the Applied Mechanics Division of the American Society of Mechanical Engineers in December last, into a function wholly and variously devised to honour Prof. S. Timoshenko, who then completed his sixtieth year. The most impressive event in a programme of appreciative items and speeches was undoubtedly the presentation to Prof. Timoshenko of a commemorative volume to which twenty-nine engineers and men of science of international reputation contributed original papers. This volume has now been published and is a striking and unusual tribute to one who, on the subject range covered by the papers, is an outstanding authority. It is seldom that a teacher and investigator receives such a demonstration of regard while still actively engaged in his work; but the range and power of Prof. Timoshenko's studies, the importance of his contributions to scientific engineering and his great reputation as a teacher, have rightly won for him this notable and spontaneous tribute.

The brief outline of Prof. Timoshenko's career which prefaces the collection of papers is of great interest as showing the varied lines along whic he has progressed to the position of a leadin authority in the use of analytical methods o behalf of technical problems. While Timoshenk considers himself primarily a teacher and prefer the academic life, his work shows his direc concern with the practical issues of analytica processes; and even his most theoretical studie are enriched by a regard for the technical applications possible to the methods elucidated or derived This is, of course, a natural outcome of the wid experience acquired in the tenure of importan research and consulting positions in industry; an when such experience is allied to the exceptiona analytical powers that have made him famous a the occupant of professorial chairs in Russia an America, the results are bound to be valuable an are rightly acclaimed. His publications mak an impressive list comprising five books an twenty-three papers in Russian and ten book and forty-eight papers in English, French o German.

The twenty-nine papers in this commemorativ volume cover a wide field in the subject of th mechanics of solids, and the topics treated ar highly appropriate considering the aim an inspiration. The majority are on theoretical processes and applications of theory to stress analysi and vibration subjects, on which lines Timoshenk has written very extensively. Fatigue and cree of metals receive considerable attention, whil special subjects like photo-electricity and frictio are also represented. Mainly the authors ar American friends and associates, but admirer oad are also well represented. Papers are uded by Föppl, Prandtl, von Mises, Huber, thwell and Taylor.

uch a book dedicated to such an authority uld give a true reflection of modern methods problems. In this it does not fail. Buckling stability studies ; critical conditions and plex vibration systems ; studies in creep and stic flow characteristics ; on fatigue data and mechanism of friction ; on methods of analysis calculation ; on basic equations ; in reviews of development, etc., are tackled with power and highly specialized knowledge. The range must be examined to be appreciated. It would be impossible even to detail the themes here, and to select a few for individual mention would be invidious and contrary to the spirit of the publication. The volume is a storehouse of advanced method and knowledge, and forms a fitting and graceful tribute to one who is universally acknowledged to be a leading exponent of the lines studied.

MEXICO: PRESENT AND PAST

An Eye-Witness of Mexico

R. H. K. Marett. Pp. xi + 268 + 8 plates. ndon, New York and Toronto : Oxford Unisity Press, 1939.) 8*s*. 6*d*. net.

Mexican Mosaic

Rodney Gallop. Pp. 300 + 48 plates. (London: ber and Faber, Ltd., 1939.) 15*s*. net.

these two books, widely different aspects of Mexico are presented ; but they should be d in conjunction, if it is desired to obtain a nplete picture of what Mexico has become after r hundred years of contact with European ilization. The term 'contact' is used advisedly. hough it is a common assumption that the ple of what is generally called Latin America the heirs of Spanish, or more strictly Iberic ture, of most of them, at least so far as the eral run of the populace is concerned, it would more correct to say that their inheritance is damentally Indian, but with modifications by ropean tradition and forms of religious belief. is is certainly true of Mexico, perhaps above all others ; for, of the Mexican population one rd is of pure Indian stock, and not more than sixth is of unmixed white blood. Sixty ferent languages or dialects are still spoken hin its borders and more than a million of the ple have no Spanish. In the north, indigenous lian tribes, Yaqui, Cora, Tarahumare and ers, are virtually untouched by modern civiltion.

(1) In this remarkably varied society, ranging m a comparatively advanced modern civilizan to the primitive Indian, it is not surprising find that there is much that is instructive for iologist and anthropologist. Mr. Marett, as author of a work on Mexican archæology, is ly alive to the claims of the past, but here he concerned mainly with present-day tendencies, though he is able at times to add point to his argument by references to earlier history. He examines present trends in politics, thought and belief, development in social relations and above all in the competitive struggle now taking place between agrarianism and industrialization. In these matters his business experience in Mexico, extending over some years, as well as his social contacts through his marriage with a Mexican lady, enable him to speak with a double, and for a European, exceptional authority.

(2) Mr. Gallop, on the other hand, is not concerned with forward movement. His interests lie in the past, the survival in custom, belief, ritual and practice among the populace of much which in all essentials is not European, but Indian, handed down by tradition from the time of the Spanish conquest and probably from long before.

Mr. Gallop came to the study of the Mexican people with an intimate knowledge of the people and folk-lore of northern Spain, the Basques in particular, and therefore is well qualified for the task of disentangling the threads of Spanish influence from the Indian strands with which it is interwoven. On the religious processions, dances and feasts which form so large an element in popular practice, he is able to speak with especial confidence, as, for example, in his analysis of the cult of Our Lady of Guadeloup, in which he sees, with good reason, that it is essentially the ritual ceremonial of the Aztec goddess of fertility. From the various feasts and ceremonies which Mr. Gallop records, more especially the ritual battles and the survival of the Indian ball game, it is evident that the cult of fertility is no less prominent in the lives of the modern Mexicans, even if not always consciously, than it was among their ancestors.

THE CELL AND PROTOPLASM

SYMPOSIUM AT STANFORD UNIVERSITY

By Prof. C. V. Taylor,
Stanford University, California

THE Symposium on the "Cell and Protoplasm", which was convened at Stanford University, California, during June 30–July 5, began on the last evening of sessions of the Pacific Division of the American Association for the Advancement of Science and closed on the day of registration for the Sixteenth National Colloid Symposium. This time relation would partly account for the large attendance at the Cell Symposium, which increased with each session to an audience of about seven hundred at the closing lecture on "Structural Units" by Prof. J. D. Bernal, of the University of London.

The attendance and growing interest that marked this commemorative Symposium can be accredited primarily to the excellence of the papers presented—all by investigators of merited eminence. Their number included several distinguished biologists whose names have been familiar in the front ranks of biological science for more than a quarter of a century. Among the other participants were those whose more recent physical and chemical analyses of the cell and its protoplasmic constituents have greatly extended the confines of biological knowledge and have doubtless pointed the way for further productive researches of fundamental importance.

In all, thirteen American men of science participated, representing eleven universities and research institutes, and three visitors from Europe: Prof. A. Szent-Györgyi of Hungary, Prof. Hugo Theorell of Sweden and Prof. J. D. Bernal of Great Britain.

Of the papers presented, one each morning, afternoon and evening of the five-day session, the first three were concerned with early and modern concepts of the cell and protoplasm.

In the initial address on "An Historical Account of Cell and Protoplasm Concepts", Prof. E. G. Conklin of Princeton University re-emphasized the social nature of scientific discovery in which the end result of successive achievements of many minds is often given undue recognition. Thus credit for the formulation of the cell theory as commonly accorded to Schleiden and Schwann was believed unwarranted because their accounts had been antedated many years by the published results of various workers, beginning notably with Robert Hooke (1667).

The second paper, by Prof. Robert Chambers New York University, on "The Micromanipulati of Living Cells", essentially resolved our mode concepts of the living cell as a protoplasmic u to the unified nature and interrelations of molecular constituents. As illustrated in a moti picture, the protein constituents of the livi protoplasm tend to retain their integrated state the presence of an engulfed droplet of oil, althou upon cytolysis, induced through mechanical d ruption of the nucleus or otherwise, a prote 'skin' forms and becomes wrinkled around the droplet. This film formation likewise ensues wh such a droplet is added to a protein solution on microscope slide. This integrated protein fram work of living protoplasm, which may be demo strated also by the air-driven ultracentrifug strongly indicates a multimolecular organizati for the living cell.

Another modern aspect of protoplasmic co stitution, gained chiefly through studies on prot plasmic elaborations, was presented in the thi paper, by Prof. I. W. Bailey of Harvard Universit on "The Cell Wall and Protoplasm". Clearly t structural nature of the cellulose wall laid do by the plant protoplasm should offer invaluab clues to the nature and spatial relations of t protoplasmic constituents. Hence, the regulari of a highly specific and characteristic structur pattern—whether concentric, radial, ramifying radio-centric—of a given cell wall evidently reflec a potential pattern in the arrangement and orient tion of the protoplasmic constituents from whic the wall is derived. All evidence thus far indicat that the cellulose matrix of the cell walls of high plants is a continuous rather than a discontinuo system of anastomosed chain-molecules the lo axis of which is oriented parallel to the long axis the cellulose fibril. They exhibit positive anisotro and sharply defined extinction angles in mon chromatic polarized light. At present, there is reliable evidence that the structural framework the cell wall is ever composed of any random oriented chain-molecules.

Complementing these three papers on the c and protoplasm, there followed two on the c and chromosomes. The first of these was giv by Prof. H. S. Jennings of the Johns Hopki iversity on "Chromosomes and Cytoplasm in the)tozoa", and the second by Prof. Richard Goldımidt of the University of California on "Genes l Chromosomes".

The well-known nuclear cycle that recurs with h cell division during the ontogeny of a multi- lular organism was cited by Prof. Jennings as cial evidence of material interchanges between nucleus and cytoplasm. Accordingly, each ndensed chromosome enlarges during the later ases of mitosis to become vesicular from material en up from the cytoplasm. Within the resulting tiguous chromosome vesicles which constitute reformed nucleus, the newly acquired cyto- smic material is altered and, as such, is returned in to the surrounding cytoplasm upon the sequent breakdown of the vesicular wall of each omosome, the residue of which again condenses the following mitosis. These cyclic interchanges l transformations apparently provide the essential chanism of cellular differentiations both in the ogeny of multicellular organisms and in the racial iations of these and of unicellular organisms. illustrative of the latter, De Garis's recent results m crossing large and small races of Paramecium re discussed. These results showed that the conjugants, having unlike cytoplasms but like lei, retained their size differences for about nty-two generations, whereupon these differ- es gradually disappeared. Evidently, there- e, the two different cytoplasms were finally nsformed by the like nuclei such that the two es of unequal size came to have the same size. By what mechanism of the nucleus the cyclic difications, and so racial differences, may be cted was discussed in the succeeding paper by f. Goldschmidt. His thesis tended to discount commonly accepted gene theory of Mendelian edity, and proposed instead a chromosome theory which the occurrence of genes as discrete entities, anged bead-like in a definite order, need not be umed. Taking into account the similarities in omosome form and structure in the cells of all anisms, wherein a visible fibril-like core may resent a single protein unit of definite stoichio- tric properties along its axis, it would be more accord with recent X-ray, chemical and polari- tric analyses to identify the chromosome as a mical unit. Such a unit might show any ount of differential chemical complexity in erent chain-molecules of similar length. This cept would ascribe to the chromosome a linear tern and would account for mutational changes e bar-effect, mosaicism, position-effect, etc.) as to changes in the chromosomal pattern (inver- ns, translocations, duplication of parts, etc.) her than to changes within discrete particles, or es, of molecular order.

The demonstrable interrelations between cytoplasm and nucleus which would account for differentiation in both the individual and the race obviously represent but one of the two major components in the fundamental phenomena of living things. The other essential component is, of course, the environment. The role of environmental factors was well exemplified in the three papers that followed on developmental aspects of the cell and its relation to the organism. These included: "Cellular Differentiation and External Environment" by Prof. C. M. Child of the University of Chicago and Stanford University, "Cellular Differentiation and Internal Environment" by Prof. Ross G. Harrison of Yale University, and "Cell and Organism" by Prof. C. A. Kofoid of the University of California.

The external environment of the primordial cell, according to Prof. Child, is a determining factor in its differentiation at the very onset of development. The cell's primordial pattern is essentially a surface-interior pattern which reflects an intimate relationship with its environment. Also, by action of a suitable differential in its external environment, its polar or axiate differentiation is duly determined. Any one or more of various environmental differentials may induce this superimposed axiate pattern, as demonstrated, for example, in Whitaker's experimental studies on the ova of Fucus, as well as in numerous previous experiments by Prof. Child. Accordingly, the axiate pattern arises as a gradient which is initially quantitative in nature and which, once established, constitutes a gradient in rate of metabolic activity. Moreover, this environmentally induced axial or metabolic gradient then conditions the production and transfer of active constituents (chemical substances) in differentiating cells and so predetermines the course of later development.

Factors of differentiation in later stages of early development were discussed by Prof. Harrison as factors of the internal environment. These were illustrated especially from his extensive transplantation experiments on amphibian larvæ. Here the developmental pattern, which has progressed well beyond the initial axiate stage of Prof. Child's account, has demonstrably a primary cellular locus ('organizer') in the region of the dorsal lip of the blastopore and later various secondary loci, which determine organ differentiation throughout ensuing development. Depending upon the age of donor and of host as well as on the piece removed and its disposition where transplanted, the fate of the transplant and its effect upon the organogeny of the host were strikingly illustrated. From this it was evident that the fate and effect of a developing part are a function of its relation to other parts. This fundamental relationship obviously marks the internal environment of cellular differentiation.

In the succeeding paper, presented by Prof. Kofoid, it was emphasized, however, that even were the roles of both genetic and environmental factors of ontogenetic development well understood, that knowledge, essential as it must be, could constitute only part of any adequate understanding of the cell and organism. For the organism, beginning its individuality as a primordial cell, represents in its complete life-history not only the ontogeny that follows its unicellular stage but also the phylogeny preceding that stage. All organisms exhibit in this fundamental respect comparable life histories which may include, even for numerous so-called unicellular forms, a multicellular as well as a unicellular phase. Accordingly, it is only in terms of their total life-history, as an expression of their evolutionary and developmental history, that the cellular organization of living things can have basic significance and so the results of fundamental investigations a satisfactory basis of interpretation.

The two lectures that followed, one on "Chemical Aspects of Microorganisms" by Prof. C. B. van Niel of Stanford University, and the other on "The Structure of Viruses" by Dr. W. M. Stanley of the Rockefeller Institute, marked a transition from considerations of the cell and protoplasm of the more conspicuously cellular organisms to a discussion of the subcellular bacteria and of those ultramicroscopic, reproducing entities, the viruses, whose systematic status, whether animate or inanimate, apparently remains a problem of great moment.

Recognizing Schwann's important contribution not only to the formulation of the cell theory but also to the concept of yeast cells as vital agents of alcoholic fermentation, Prof. van Niel recounted the later developments of that concept, beginning especially with Pasteur, which have now led to a distinctly basic and far-reaching generalization. This generalization affirms that all chemical activities of living organisms are fundamentally hydrogen transfer reactions. Postulated first by Wieland for respiration as essentially a dehydrogenation of the respiratory substrate with oxygen or some other agent as the final hydrogen acceptor, this concept has become expanded by Kluyver and others to its present broadest generalization. Thus enzyme activity in metabolic processes serves primarily to facilitate hydrogen transfer reactions. It now appears that in the catabolic process this leads to the formation of products from which are directly synthesized the building stones of cell growth and differentiation by means of thermodynamically spontaneous reactions. This comprehensive generalization re-emphasizes the processes common to living things as the fundamental processes, the elucidation of which provides our point of departure for an adequate understanding of the more complex vital phenomena.

In this respect, the succeeding discussion on
viruses by Dr. Stanley was distinctly of fun
mental significance. It now appears that th
entities represent a margin of animate Nat
beyond the limits of cellular organization
commonly understood, yet they exhibit propert
of organic synthesis and reproduction characteri
of the living cell. Evidently their size relati
alone are not definitive, since they are larger th
some well-known microbes but several times sma
than some protein molecules. Their apparen
complete dependence on a living cell for th
reproduction would place them among oblig
parasites the nutrient requirements of which
highly specific and, at present, beyond experimen
duplication. Their essential nature, however, m
have a counterpart in the chromosomal genes of
cell nucleus or in other known protoplas
constituents such as the enzymes—a relations
which would obviously carry fundamental im
cations.

Some of the major advances in modern researc
on the cell have had to do with its active pro
plasmic constituents. Résumés of some rec
results were presented on "Enzymes" by P
Hugo Theorell of the University of Stockho
on "Plant Hormones", by Prof. F. W. We
California Institute of Technology, and on "Vi
mins" by Prof A. Szent-Györgyi of the Univers
of Szeged.

The common theme of these discussions dem
strated the essential relations between th
several active constituents. The common role
enzymes in the formation or release of linka
within the carbon chain is referable initially to
prosthetic groups; and for a number of w
known enzymes, the vitamin nature of their act
groups is now established. Thus, Prof. Theo
isolated the prosthetic group of the 'yell
enzymes' from the protein component by means
electrophoresis and identified this active gro
with vitamin B_2. It is now known also that vi
min B_1, including its pyrophosphate derivative,
identical with the prosthetic group of the enzy
carboxylase, and that the anti-pellagra vitamin
identical with the nicotinic acid amide, which is t
essential part of the prosthetic group of vari
dehydrogenases.

Enzyme specificity, however, is evidently
due to the prosthetic group but to its associat
protein molecule—thus denoting a relations
between activating and reacting components of t
cell which may come to account fundamentally
all biological specificity. According to Prof We
therefore, the more generalized activity of t
growth hormones can be attributed to their id
tity with prosthetic groups. This was well ill
trated by the multiple effects of auxin in

ngation, bud inhibition, root formation and bably other functions inside the plant. The iation of these growth processes, or their ibition, is traceable to the effect of diffusing or e-moving auxin on the translocation of other ential growth factors. But the specificity of s effect is inherent in the co-growth factors of the oting tissues. The production of these essential ive groups by some cells, such as those of the wing tip of a coleoptile, and the transport of se groups to other cells of the plant, which ough cellular differentiation have lost this ducing capacity, afford an excellent illustration the interdependence of cells and the functional egration of the various differentiated organs. ese relationships obviously underlie a unity in plant organism that is entirely comparable h that in the animal.

These considerations of enzymes and growth mones clearly indicate the essential nature of vitamins. As re-emphasized by Prof. Szent-örgyi, vitamins may be identified with the sthetic group of certain enzymes, and differ from ormone chiefly through the accident of nomenture, according to the source of production. us for rats or plants, ascorbic acid is not a amin since they themselves are able to synthee it. In the same sense, thiamin is a vitamin for mals, a hormone in some plants and a vitamin other plants, depending only on their powers synthesis. Obviously these relationships give ther evidence of the fundamental unity in the nt and animal kingdoms, and, in terms of the yme concept noted above, the vitamins contute an important key to a better understanding the essential nature of protoplasm and the cell.

The three concluding papers, as originally nned, effectively linked this Symposium with National Colloid Symposium which directly lowed. These included: "The Molecular Struce of Protoplasm" by Prof. O. L. Sponsler of the iversity of California at Los Angeles, "Protosm and Colloids" by Prof. L. V. Heilbrunn of University of Pennsylvania, and "Structural its" by Prof. J. D. Bernal of the University of ndon.

The general concept of the living cell as an ganized protoplasmic unit, which was stressed in egoing discussions, evidently presupposes for its toplasm a fundamental architecture, that is, an egrated spatial arrangement of the protoplasmic stituents.

An analysis of this architecture was presented Prof. Sponsler, as based on the known molecular stitution of protoplasm and computed from w fairly well-established dimensions of its tein chains and their linkages through hydrogen nds. Assuming a degree of protoplasmic homogeneity, it was concluded that the protoplasm comprises parallel protein chains, of dimensions about 1000 A. by 10 A. by 4·5 A., which are laterally united by water hydration centres and which, in turn, compose a sponge-like framework intercalated with water containing the various solutes. From this elementary protoplasmic architecture is derived the fundamental pattern of the primordial cell which, through developmental differentiation, gives rise to the tissue cells and organs of the adult organism, as recounted in the earlier discussions.

The colloidal properties of protoplasm and its cellular differentiation were variously exemplified in the paper presented by Prof. Heilbrunn. His recent investigations have demonstrated especially a localization in the cortex of the cell of calcium which, upon appropriate stimulus, is released within and so effects a gelation of the protoplasm involving contraction. Further evidences of this gelating effect were found upon exposing cut surfaces of cells to various concentrations of calcium salts. Thereupon a reversible limiting membrane was formed on the cut surface, or a bulb-like contraction was locally induced, due to the penetrated calcium. Thus the age-old problem of contractility, a common property of protoplasm, may find its solution normally in the localization and release of calcium in the cell's cortex.

Recalling the emphasis given throughout the Symposium to the structural aspects of protoplasm, Prof. Bernal, in presenting the final paper, urged that consideration of the energy relations was equally important, since not only do the energies involved determine the sort of structure possible but also their nature must be known in order to account for that structure. These energies relate primarily to the protein constituents of the protoplasm, a model for which may be found in the tobacco mosaic virus when contained in known salt solutions. Here the virus entities, which are long protein molecules, become orientated in striking spindle-like patterns, or tactoids, and their regular distances apart vary directly with the concentration of the salt solution. Evidently long-range forces between the virus entities are operative through the ionic atmosphere of the surrounding medium with which the former are in equilibrium. The magnitude and direction of forces inside the tactoid pattern are different from those on the outside. These differences, in fact, account for the pattern formation. Apparently analogous forces may similarly account for the formation of the mitotic figure and the ensuing phenomena during the mitosis of the living cell.

These papers are soon to be published in book form by the American Association for the Advancement of Science.

THE RELATIVITY OF TIME

By Prof. Herbert Dingle,

Imperial College of Science and Technology, London

THE view is widely held that, according to the restricted theory of relativity, moving measuring rods are shortened in the direction of motion, and moving clocks run slow, in the ratio $\left(1 - \frac{v^2}{c^2}\right)^{1/2} : 1$, where v is the velocity of the rods and clocks relative to instruments otherwise identical but assumed to be at rest. This view is correct so far as measuring rods are concerned; but incorrect with respect to clocks.

No metaphysical significance is here implied with regard to length and time. The statement that a moving rod is shortened means that if an observer stands at the centre of a relatively stationary rigid scale, past which a parallel scale, of equal length when relatively at rest, moves in the direction of its length; and if light signals are emitted from the two ends of the first scale at the instants when the corresponding ends of the other are coincident therewith; then the signal from the rear end will reach the observer before that from the other end, by an interval consistent with the postulated contraction. The word 'contraction' is, of course, to some extent metaphorical, because the scale which is said to be contracted is simply the one on which the observer is not situated. A more direct expression of the fact is that the 'length' of a scale is measured not by l as ordinarily defined, but by $l\left(1 - \frac{v^2}{c^2}\right)^{1/2}$: it is then unnecessary to imagine that anything has happened to either scale.

The statement that a moving clock is slowed down by a definite factor means that if, by any means ordinarily recognized as physically legitimate, an observer compares the rates of two clocks, one moving and the other stationary with respect to himself, he will find them to differ in the manner indicated.

There is no direct evidence for either statement, the experimental difficulties being too great. Circumstantial evidence, however, for the effect described as a contraction of a moving rod is given by the Michelson-Morley and other experiments, and the observational justification for accepting it as verified is very strong. There is no evidence of any kind for the definite retardation of clocks, and it is impossible that there could be, for there is in physics no explicit definition of a clock. The statement that a clock is slowed down in such a such a proportion is therefore meaningless.

A clock is any mechanism which successiv records time intervals certified as equal by co parison with the standard intervals adopted Greenwich and other observatories: the charac of the mechanism need not be specified so long the recorded intervals satisfy this condition. I us, then, imagine an instrument of hour-gl type, in which a succession of precisely simi particles (for example, grains of sand, drops water) fall at the standard rate into a recepta The time of occurrence of any event is th indicated by the number of particles, N, whi have fallen between some chosen zero instant a the instant of occurrence of that event. If M a V are respectively the mass and volume of particle, then the time is equally well indicated MN or VN (in each case, of course, a consta factor may be introduced to give the unit of ti any desired value). For such a clock at rest, th the time t between two events is proportional N, MN or VN.

Now set the clock moving with velocity v, a suppose that when it is moving uniformly, N changed to N'. Then, by the well-known formu MN changes to $MN'\left(1 - \frac{v^2}{c^2}\right)^{-1/2}$, and VN $VN'\left(1 - \frac{v^2}{c^2}\right)^{1/2}$. If, then, dt and dt' be intervals recorded by the stationary and movi clocks, respectively, between the same events, ratio dt'/dt will be different in the three cases, shown in the accompanying table:

dt	dt'	dt'/dt
N	N'	N'/N
MN	$N'M\left(\frac{1}{1-v^2/c^2}\right)^{1/2}$	$N'/N\left(\frac{1}{1-v^2/c^2}\right)^{1/2}$
VN	$N'V(1-v^2/c^2)^{1/2}$	$N'/N(1-v^2/c^2)^{1/2}$

All three clocks are equally 'legitimate': he the restricted theory of relativity gives no inform tion, and makes no assumption, about the haviour of moving clocks.

It is certain, however, that the mathemati requirements of the theory are represented by Lorentz transformation formulæ, according which dt'/dt is unequivocally determined. follows, then, that the time-coordinate of mulæ does not represent (except possibly identally in a particular case) the reading of a ok. What, then, does it represent ?

o answer this question we note first that t is tainly equal in value to the reading of a clock rest, though t' is in general not that of a clock motion. We therefore inquire what t essentially The clock with whose readings it agrees was ed by a mean solar time clock at Greenwich, us say; that, in turn, by a sidereal clock; and t by the revolutions of the celestial sphere at is, rotations of the Earth). Here Greenwich ps.

t would seem, then, that the time scale of the sics of stationary systems is that according to ich successive sidereal rotations of the Earth upy equal times. But that cannot be so, for are told that the Earth itself is slowing down. lifferent, and still more fundamental, standard herefore implied: What standard is that ?

he only way to answer this question is to mine the evidence for the Earth's retardation. is found in the fact that there is a discrepancy ween the calculated and the recorded tracks of ient eclipses. If the rotation of the Earth ually defined the unit of time, the conclusion ld necessarily be that the principles (namely, laws of Newtonian mechanics) on which the ulations were based were wrong. The con- sion actually drawn, however, is that the repancy is due to the gradual lengthening the day. The drawing of this conclusion mits us to the time scale necessary to justify wton's laws of motion. What is that time le ?

he first law is sufficient for our purpose. It s that a body free from external influences will ve uniformly; that is, equal times are those which such a body covers equal distances. At t we have reached finality. This is the time le represented by the co-ordinate t in stationary tems. A clock recording this time scale (we call it an 'ideal' clock) would be a particle ving freely, without friction, along an infinite ce-measuring scale in a region free from vitational and other fields of force: the 'time' uld be the reading of the scale at the instan- eous position of the particle.

o such clock can be made, and we have there- e to use various artificial constructions, with plicated controlling mechanisms, in order to ermine what its indications would be. It is surprising, therefore, that the corrections to applied to the readings of such artificial con- ctions when they are set moving, in order to lize the readings which the ideal clock would e if it were set moving, are almost as various the constructions themselves.

We can now see the meaning of t'. If t is the reading of an ideal clock at rest, t' must be that of an ideal clock in motion: or, in other words, t' refers to the time scale which will make the laws of mechanics hold for moving systems. There is no need to make an experiment (which in any case is impossible) to determine the relation of dt' to dt, for that relation is determined logically from the fact of the Fitzgerald contraction. Suppose an ideal clock is set moving in the direction of its space-measuring scale. Since there is, by definition, no force between the particle and that scale, the velocity of the particle relative to the scale must be considered unchanged; that is, the time which the particle of the stationary clock takes to move over n divisions of its scale must be considered equal to the time which the particle of the moving clock takes to move over n divisions of *its* scale. But the latter scale is contracted with respect to the other in the ratio $\left(1-\frac{v^2}{c^2}\right)^{1/2}:1$. Hence the particle of the moving clock moves a shorter distance in the same time: that is, the moving clock must be considered to be running slower than the stationary one in the ratio mentioned.

It appears, then, that the transformation formula for t is a logical consequence of that for x. Only the latter is based on experiment; the former is the necessary consequence if Newtonian mechanics is to hold good for uniformly moving systems despite the change of x. It is useless to look for experimental evidence for the change of t, for if, in any attempted experiment in which the Fitzgerald space contraction were assumed, the Lorentz formulæ were not verified, the only possible conclusion would be that the clock used was not an ideal one, and the necessary corrections would have to be applied to its readings.

Kennedy and Thorndike, in describing their celebrated repetition of the Michelson-Morley experiment with an interferometer having unequal arms[1], state that "Among the several classical experiments which suggested the restricted principle of relativity there appears to be none in which any question as to the nature of time is involved. . . . Hence, although such experiments have suggested the relativity theory, they do not form a sufficient basis for the logical derivation of it." This, as we have seen, is erroneous. What the Kennedy-Thorndike experiment provided was not, as the authors stated, confirmation of the Lorentz transformation for time, but evidence that, if light be regarded in the ordinary way as having a certain "frequency", then that frequency must be subject to the Lorentz transformation if the Fitzgerald space transformation also be assumed. In other words, the Kennedy-Thorndike experiment showed that light (or, if hypotheses be introduced, a radiating atom) behaves as an ideal clock. This, of course, is highly figurative language, because it is a 'clock' which can neither tell the time nor be used to measure time intervals. The literal interpretation of the experiment is that Newtonian mechanics is peculiarly fitted for the treatment of light as a periodic phenomenon because the association of time and space measurements implied in Newton's first law is just that which makes λ and ν change by reciprocal factors, thus keeping the velocity constant.

Incidentally, two things may be noticed. First, the frequently heard statement that relativity has brought about a fusion of space and time has nothing mystical about it and it is not true. It is not mystical because the 'nature' of space and time is not involved; all that we are concerned with is the fitting together of measurements made in various ways. The statement is not true because the fusion of space and time, in the only sense in which it exists, was made by Newton when he chose, as a measure of time, the spaces covered by a freely moving body. What relativity has done in this regard is simply to show how that measure can be preserved in face of the experimental fact of the Fitzgerald space contraction.

The second point is that the conformability of light to Newtonian mechanics, established by the Michelson-Morley and Kennedy-Thorndike experiments, makes it possible to define correspond units of space and time in terms of light inst of Newton's hypothetical "uniformly mov body". This is, in fact, what Milne does in theory of 'kinematical relativity'. In practice two procedures are equivalent, at least to a h degree of approximation, as we know from exp ment. Epistemologically, however, they dif- profoundly, since Milne's definitions, being ba on theoretically possible observations, are, principle, rigorously realizable; whereas Newto are ideal, and any observed departure of a mov body from uniformity of motion can be ascrit either to the time scale used or to the interfere of a force. In other words, Newton's first l provides a language but says nothing; it cann therefore, be convicted of untruth, and the wo that can happen is that the language may be fou inconvenient or incapable of providing express for everything we find it necessary to say. Miln postulates, on the other hand, are definite sta ments, and may be falsified by observation. T chance that this will happen is, of course, m imized by the fact that they are made to confo to all the experimental knowledge available at present time. This safeguard was introduced Milne when he modified his theory so as to ident the originally unspecified signals used by observ with light beams.

OBITUARIES

Mr. M. A. Bailey

THE scientific career of Maurice Armand Bailey ran its course to memorable achievement with what almost seemed to be predestined continuity. If circumstance played its part, a mind splendidly equipped for investigation, linked to a grand character, were the prime forces.

From Dulwich Bailey went up to Clare College, Cambridge, to read for the Natural Sciences Tripos and then for the diploma in agricultural science. After three years as a research student at the John Innes Horticultural Institution he joined the Royal Field Artillery in 1915, gaining in France the Military Cross and the rank of brigade major.

The appointment as senior botanist to the Ministry of Agriculture, Egypt, in 1919 turned the young geneticist into a plant breeder. For the next six years Bailey's studies of the cotton plant, recorded in a few excellent papers, developed a scientific attitude and procedure in practical breeding such as have rarely been achieved in that difficult art.

Transfer to the Sudan as plant breeder under the Empire Cotton Growing Corporation (attached to the Sudan Government) gave Bailey a great probl and a grand chance. In that country cotton gove prosperity. A great irrigation scheme in the Ge makes cotton-growing possible where rainfall is scant and uncertain for any normal agriculture. I the soil is commonly recognized as the most intra able clay in the world, and climatic peculiarities many seasons check the growth of cotton desp irrigation.

Average yields of cotton of 3·5 kantars a fed had become customary and were remunerative, in 1923 a virus disease, leaf curl, was reported, occurrence being exceedingly rare. It spread swiftly that by 1929 the whole Gezira, involv 200,000 acres of cotton, was seriously affected. the ensuing years cotton yield fluctuated dangerou but search for causes in soil factors, in seaso effects and in disease, was for a time in vain. L curl evidently played a great part, and in one year yields dropped to 1·36 kantars. Sudan fortu were gravely menaced, but an outstanding combi tion of research in plant breeding, in entomology, mycology, and in crop husbandry gained a victo which the remarkable speed and extent are shown the cotton yields of the years 1935–38, which were ·5, 3·72, 4·47 and 4·55 kantars per feddan re- ctively.

When Bailey retired from the Sudan in 1938, ton growing in the Gezira had been rescued and tial plans had been laid for the wider agricultural elopment of the whole country, including the ı-irrigated south. Hope that the ability and racter by which the Sudan had profited would y a great part in the National Institute of Agri- tural Botany, which Bailey came home to direct, s ended by his death in Cambridge on October 16 t at the age of forty-nine.

t was specially fitting that a scientific worker n and educated in England and provided by ypt with great opportunities for studying cotton uld do his culminating work in the Sudan, in ich these two countries have a condominium. He yed two parts there. For the first six years plant eding occupied all his time: for the remaining en he was director of agricultural research. It Bailey's clear planning and quiet persistent uence which led to the complete reorganization the research service. He infused into it the spirit ich has made it remarkable for success in conjoint k.

eaf curl was checked by two lines of action. The tomological, Mycological and Agricultural Sections, a series of fine investigations, identified the vector white fly, an Aleurodid) and found means of rcising a considerable degree of control over it in d practice. Meanwhile, the Plant Breeding tion set itself to examine the possibilities of aining, by selection or crossing, new varieties ich, while equal in lint qualities to the customarily wn Sakel variety and adapted to the peculiar ira environment, had the further merit of specific stance to leaf curl. Hybridization had to be carded because of its inevitable slowness, and all rt was concentrated on selection. The field was imately narrowed down to plants resulting from ingle selection out of a field crop of Sakel in the ira made by Mr. A. R. Lambert of the Botanical tion in 1926. There finally resulted two strains wn as *X* 1530 and *X* 1730 which, showing in ls all the desired attributes, had spread to an a of 130,000 acres in 1937–38. Systematic plant eding has nowhere produced a quicker or more nificant result than this. F. L. Engledow.

Prof. A. P. Orekhov

HE death occurred on October 19, at the age of y-eight, of Prof. Alexander Pavlovich Orekhov, mber of the Academy of Sciences of the U.S.S.R. rekhov was one of the most eminent experts in chemistry of alkaloids in the Soviet Union. centrating his main research on vegetable bases, ascertained that most of the alkaloids were not cifically characteristic of definite vegetable species families and that one and the same alkaloid or aloids of similar structure may be found in plants of different families. Under his guidance more than eight hundred kinds of new vegetable raw materials were studied, found mainly in the southern republics and provinces of the U.S.S.R. During this research were discovered a hundred new alkaloid-bearing plants and ten new families, previously not known to possess alkaloid-bearing representatives.

Orekhov established the structure of anabasine, salsoline, salsolidine, convolvine and certain other vegetable bases. Many of the alkaloids he isolated were afterwards identified as substances already known and obtained by other investigators from quite different vegetable raw materials. From the point of view of scientific theory, of special interest is his elucidation of the structure of the alkaloids convolamine and convolvine, which have been proved to be ethers of veratric acid and tropine. It was thus ascertained that the derivatives of tropine are encountered in quite new families hitherto not held to be alkaloid-bearing.

A. P. Orekhov created his own school of research workers, and the laboratory which he directed at the Chemical Pharmaceutical Institute attached to the Commissariat of Health became the principal centre for the study of the chemistry of alkaloids. His work on "The Chemistry of Alkaloids" is the standard work on the subject in the Soviet Union. He was elected a member of the Academy of Sciences of the U.S.S.R. in January of this year.

Prof. C. F. Shaw

The death of Prof. C. F. Shaw of California removes one of the most prominent of America's pedologists. Prof. Shaw gained a reputation from his studies in the field of pure rather than applied soil science, his name being especially associated with the question of soil classification. He spent several years studying Chinese soils, besides having a wide experience of American conditions. His revolving-disk method of measuring and specifying soil colour has been one of the more notable advances in the technique of soil physics in recent years. He was an ardent believer in the American binomial system of soil nomenclature, and had been engaged for some years prior to his death in collecting and collating a world list of 'soil-series' names, which was to serve systematic pedology as the Linnean system has served botany. G. V. J.

We regret to announce the following deaths:

Mr. P. H. Grimshaw, formerly keeper of the Natural History Department of the Royal Scottish Museum, on November 14.

Dr. R. von Ihering, chief of the Serviço Federal de Piscicultura, Rio de Janeiro, on September 15, aged fifty-six years.

Dr. T. L. Prankerd, lecturer in botany in the University of Reading, on November 11, aged sixty-one years.

Sir William Prout, K.C.M.G., O.B.E., senior consulting physician to the Colonial Office during 1927–29, on November 18, aged seventy-seven years.

NEWS AND VIEWS

Germanization and the University of Prague

Ruthless as have been the measures of repression directed by the Germans against Czech students and intellectuals for their part in the demonstrations on Independence Day, October 28, and the following days in the city of Prague, yet none will give rise to deeper resentment, nor have more far-reaching effect than the closing of the University and the technical schools. Not only do the Czech people feel a special pride in the University of Prague as the oldest University in Eastern Central Europe, but also the University has always been a central rallying point in the development of Czech national life and national culture. So long ago as the thirteenth century, Prague was a gathering place for students, and when in the middle of the fourteenth century it was recognized under a Bull of Pope Clement VI, Charles IV, Emperor and King of Bohemia, its founder, while organizing it on the model of Paris, of which he had been a student, in four "nations", intended that primarily it should serve the needs of students from Styria. Nevertheless, it drew its students from all parts of Europe, and in repute equalled the greatest of the medieval universities. It was, however, after the Napoleonic wars and in the earlier half of the nineteenth century that the University attained its greatest measure of influence in the development of a Czech national culture and consciousness. Not only was the study of the national language and antiquities taken up with ardour, but also industrial development was fostered in the movement which led to the foundation of the technical schools. In the course of events which followed on the War of 1914–18 the University has been no less active in promoting in the people a consciousness of their historical and intellectual heritage. Its suppression will have repercussions of which a better knowledge of their own history might have conveyed a warning to the Nazi leaders.

The Advancement of Science

The first quarterly part of the *Advancement of Science*, the new journal of the British Association which is being issued in place of the annual volumes published by the Association from 1831 until 1938, contains the presidential address of Sir Albert Seward, "The Western Isles through the Mists of Ages", as well as the presidential addresses to Sections D (Zoology), H (Anthropology) and K (Botany), with abstracts of communications to those Sections. An admirably written introduction reviews the Dundee meeting and the circumstances which led to the premature termination of an exceptionally promising and well-attended meeting, and also indicates the tentative policy of the new journal, which it is hoped will make a wider appeal to lay readers than an annual volume could do. The number also includes reports of research committees to Sections D, H, a K, as well as the report of the Council to the Gene Committee for the year 1938–39, and the report the Division for the Social and International Relati of Science for the same period. Among the subje which have received attention by the latter Divisi other than those forming the subject of public me ings, are the incidence of taxation on scientific search; areas and objects worthy of protection scientific grounds; recommendations on details manded in census returns and their analysis; scient news in the Press; scientific exhibitions; co-ope tion with the International Council of Scientific Uni in relation to questionnaires on science and socie and assisting the Society for the Protection of Scie and Learning. The number also includes a f instalment of a scientific survey of Dundee a district.

Soil Problems in the Tropics

In the editorial article entitled "White Settlem in the Tropics" of Nature, July 29, 1939, refere was made to the insistence in the report of Commission appointed to inquire into the possibili of white settlement in British Guiana on the ' herent poverty of many, perhaps most, tropical so in contrast to earlier beliefs in their inexhausti fertility. Writing from the East African Resea Station, Amani, Mr. G. Milne foresees a danger t facile generalizations regarding tropical soils as s may result. He points out that "tropical soils t to be poor when the climate is very wet, when soils are of advanced maturity, when (like any ot soils) they have suffered from man-accelera erosion, or when their parent materials have b exhausted of plant nutrients by previous geologi processes". One or more of these factors has rende huge areas of East Africa infertile, but there are large tracts where pessimism on grounds of intri soil infertility alone is not justified. Recent w has made it clear that neither the luxuriance natural rain-forest cover nor of grassland vegetat affords a reliable guide to the agricultural value soils (Hardy, F., *Trop. Agric.*, 13, 315; 19 Walter, H., *Forstliche Wochenschrift Silva*, 22, 2 1936: Milne, G., *East African Agric. J.*, July 19 and that therefore an ecological survey cannot t the place of a soil survey. The fundamental princi seems to be that a high forest has matured al with the soil that nourished it; in the old age both, the forest comes to depend very little on furt material supplies from a highly leached and poverished soil. Two things seem clear: one that principles of good soil management in the tro have yet to be fully understood, the other t tropical soils are liable under improper managem

NATURE

SUPPLEMENT

Vol. 144 SATURDAY, NOVEMBER 25, 1939 No. 3656

SHORT REVIEWS

AGRICULTURE

Humus
Origin, Chemical Composition and Importance in Nature. By Prof. Selman A. Waksman. Second dition, revised. Pp. xiv+526. (London: Baillière, Tindall and Cox, 1938.) 30*s*.

THIS treatise, first published in 1936, is now recognized as the standard text-book of the cience of humus, or 'humology', as the science has been called. The literature of humus is so diffused hat the treatment of the subject in agricultural and soil science text-books must necessarily be somewhat superficial and inadequate to the importance of the subject. The fact that the chemistry, physics and biology of humus do not lend themselves to easy nterpretation in terms of orthodox science is the main stumbling-block to progress in knowledge of he soil.

The book is in three parts. The first deals with the historical development of humus studies, the changing conceptions of the origin and composition of humus, and the reasons for the highly confused state of our knowledge of it. The nine chapters comprising the second part begin with the more rational approach to the subject, adopted about the commencement of the present century, in which the study of plant residues and the processes of their decomposition led to the modern conception of humus as a highly complex and changing group of organic and mineral substances. The decomposition of humus and its functions and applications in agriculture and industry occupy the remaining five chapters of the book, including a new chapter on humus and soil conservation.

The bibliography of 1608 references indicates the immense amount of work that has been devoted both to the investigation of humus and to the compilation of the book. If the amount of definite knowledge gained is disproportionately small to the amount of labour expended, it is nevertheless some of the most significant in the whole realm of soil science, and Dr. Waksman is to be congratulated on his selection of relevant facts and their condensation into a very readable and intelligible form.

Ce qu'il faut savoir des plantes des montagnes
Par P. Du Manoir. (Savoir en histoire naturelle, Vol. 5.) Pp. 54+40 plates. (Paris: Paul Lechevalier, 1939.) 16 francs.

Ce qu'il faut savoir pour manger les bons champignons
Par G. Portevin. (Savoir en histoire naturelle, Vol. 6.) Pp. 94. (Paris: Paul Lechevalier, 1939.) 12 francs.

THESE two little monographs are attractive in design, but any botanist would take issue with the claim that the contents represent what it is necessary to know on the subjects dealt with. Rather are they harmful in suggesting that, in the case of the alpine plants, with an idea of colour and size and a few notes on habitat, plants may be recognized by comparison with a rather impressionist representation in colours, usually of the flowering shoot alone.

The monograph on fungi does not pretend that the amateur can be sure to collect edible fungi on the basis of the brief descriptions of the fungi that it contains; it contents itself rather with suggestions as to modes of preparing the edible forms for the table when they are collected. Emphatically, however, this restricted field does not include what it is necessary to know before collecting and cooking fungi for the table.

ARCHAEOLOGY AND ETHNOLOGY

Buried Empires
The Earliest Civilisations of the Middle East. By Patrick Carleton. Pp. 290+12 plates. (London: Edward Arnold and Co., 1939.) 10*s*. 6*d*. net.

MR. CARLETON has excavated in Iraq as a member of Sir Leonard Woolley's archaeological expeditions to Ur, and he is a student of cuneiform. He writes, therefore, with the authority of first-hand knowledge; and his narrative of Mesopotamian pre- and proto-history, intended primarily for the general reader rather than the expert, summarizes in a vivid and eminently readable form the results of archaeological research from the beginnings, so far back as present knowledge goes, down to the earlier half of the second millennium B.C. With commendable honesty, but also doubtless with results which will prove disconcerting to the novice in these studies, Mr. Carleton adds an appendix on the material in the tablets of Mari, discovered after the main body of his narrative was completed, and it was too late to make any drastic revision. Hence the chapters dealing with Hammurabi and the Babylonian dynastic history, at least in their chronology and its implications, must, he points out, be set aside as superseded.

A valuable feature of the book is an excellent summary of the evidence relating to the civilization of the Indus valley and discoveries at Mohenjo-daro and Harappa, a subject on which too little provision has hitherto been made for the interests of the uninstructed.

If Mr. Carleton's narrative, excellent as it is, is open to criticism, it is due to the fact that it follows closely the tradition of earlier writers in devoting a preponderating attention to the personalities and achievements of the rulers, and to dynastic history, whereas recent studies have tended to show that the vital importance of Mesopotamia in the history of civilization lies in its contribution to the development of culture, rather than as a series of phases of 'history' in the narrower sense generally adopted.

Monographie des Betsileo (Madagascar)

Par H.-M. Dubois. (Université de Paris: Travaux et Mémoires de l'Institut d'Ethnologie, Tome 34.) Pp. xviii+1510+10 plates. (Paris: Institut d'Ethnologie, 1938.) 275 francs.

M. DUBOIS' monumental study of the Betsileo of Madagascar, running to more than fifteen hundred pages, is the product of thirty years' patient and careful observation conducted while the author was resident among them. Not only is it encyclopædic in scope, but also it may be regarded, as one critic has said, as indeed definitive.

M. Dubois has divided his work into four parts. In the first part he describes the geographical setting and considers racial history. In the second he deals with the individual, his life and the family and social environment in which it is passed. In the third he describes religious belief; and in the fourth art, language and literature.

In his discussion of general conclusions, M. Dubois makes no claim to have solved finally the problem of origins. His racial analysis of the population of Madagascar distinguishes four racial groups or influxes—Negrillo, Negro, Negroid and Indonesian. The Betsileo are to be assigned to the Negroid; but there is in them a strong strain of the earlier Negro and Negrillo stocks. Their economy is one of rice cultivation combined with cattle raising. Descent is patrilineal; and the sense of family solidarity is strong, centring in the cult of the ancestors as the founders of the family group. In essentials, however, the religious beliefs are fundamentally a doctrine analogous to the *mana* of the Pacific, demonstrated most emphatically in their taboo practices and their relations to chiefs.

African Genesis

By Leo Frobenius and Douglas C. Fox. Pp. 26 (London: Faber and Faber, Ltd., 1938.) 12s. 6 net.

THIS volume contains a number of legends an folk-tales selected from the collections made b Dr. Leo Frobenius among the various peoples he ha visited in his numerous expeditions in Africa for th purpose of studying prehistoric rock-engravings an paintings. Hence in geographical distribution the cover a wide field, ranging from North Africa t Southern Rhodesia, and ethnically include Kabyl the Sudanese tribes, Hausa and in the south Wahung and Bathonga. Most, but not quite all, have bee selected for the light they may throw on the meanin and purpose of the rock-drawings and painting Thus in the Kabyle creation legends, the part played by bull and ram explain the prominence o these animals in the art, while the raised arms of human figure before the bull in a certain drawing i a sign of adoration, and not of panic as has bee thought. It is interesting to find what would appea to be a trace of the influence of Egyptian roya marriage custom in these legends.

The stories are sufficiently varied in style an subject to please all tastes, and their literary merit on the whole are high. The Kabyle tale of the jack and lambs, with the substitution of jackal for wol is identical with that in Grimm. "The Old Woman" a tale told by the Hausas, is a piece of stark realism but the legends of the Sudanese, especially "Gasera' Lute" of the Soninke, and "Blue Blood" of th Fulbe have the epic quality of European medieva romance.

The illustrations are drawn from the rock art an there is a praiseworthy liberality in the matter o sketch maps. The translation is excellent.

BIOLOGY

Flora of Assam

Vol. 3: Caprifoliaceæ to Plantaginaceæ. By U. N Kanjilal, A. Das, P. C. Kanjilal and R. N. De (Published under the authority of the Governmen of Assam.) Pp. x+578. (Shillong: Forest Offic 1939.) 12 rupees.

INDIA has need of provincial or regional floras, an the present volume is a welcome addition to th few existing ones. This is the third volume comprising the Gamopetalæ in the sequence of th "Genera Plantarum"; the previous volumes appeare during 1934–38.

The work has been carried out by four fores officers (the senior of whom was the author of "Fores Flora of the Jaunsar, etc., Forest Divisions", wh died some years ago), under considerable difficulties as they have access neither to a good herbarium nor to an adequate library. This handicap become evident when one turns to nomenclature. Th position is explained by the chief editor in th introduction. In some cases modern ideas have bee adopted, in others the older authors have bee followed. This will be confusing to users who canno efer to original works, particularly so as reference as not been made to the "Flora of British India" hen the combinations there used have not been etained; for example, unless one has access to Mez's onograph of the Myrsinaceæ there is nothing to ndicate that the genus Sadira was treated as Pime- ndra in the older work. Again (p. ix) it is stated hat Mez "calls *Embelia Nagushia* Don, *E. undulata* s he identified *E. Nagushia* Don with *E. vestita* Roxb. n this work Brandis has been followed." But a eference to Mez shows that it is *E. Nagushia* Clarke ot Don that is termed *E. undulata* (Wall.) Mez and hat *E. Nagushia* Don is sunk in *E. vestita* Roxb. he error is of Brandis but only detectable by a eference to Mez.

Descriptions of families, genera and species are iven, but the tendency is to pay greater attention plants of importance in forestry. There is no key the families (this may be deferred to the final olume), but keys are provided for genera and pecies when there are more than one of either, and ese in general are satisfactory.

There has been a steady improvement in the veral parts, but there are still shortcomings in the resent volume, especially in the matter of misprints.

It is not clear why certain species are treated ifferently from the rest in the same genus; for xample, under Agapetes sixteen species are included the key and are serially numbered, but seven rther species appear without numbers and with orter descriptions and in smaller type.

Despite the difficulties encountered, the authors e carrying out a task the fruits of which will rove of great assistance to all concerned with the hanerogamic flora of Assam.

he Comity of Spiders

y Dr. William Syer Bristowe. Vol. 1. (Ray Society, ol. 126, for the Year 1938.) Pp. x+228+19 plates. ondon: Bernard Quaritch, Ltd., 1939.) 25s.

THE first volume of Dr. Bristowe's "Comity of Spiders" deals mainly with the distribution of iders in Britain. Some seventy-five years have ssed since the publication of Blackwall's fine work, A History of the Spiders of Great Britain and reland", and meanwhile our knowledge of the ritish fauna has been much enriched, notably by e researches of the Rev. O. Pickard Cambridge and r. A. R. Jackson. Dr. Bristowe, himself an able d enthusiastic collector, has also made many teresting additions and these advances are incor- rated in the most useful section of his book, a list the 556 known British species under their presently cepted names. For each species the distribution ithin Britain is given by counties from records rgely made by the author himself, and the dis- ibution outside Britain, so far as known, is indicated general terms. One or two nomenclatorial changes e made, but synonyms are not otherwise listed.

The second half of the book examines the effect of vironment on distribution and, besides more neral considerations of climate, soil, and flora, it mmarizes the results of collecting in a wide variety of habitats, natural and artificial, from sewage works to Buckingham Palace gardens. Dr. Bristowe has already published much of the matter in this section during recent years in the form of short papers, but the repetition is justified in a general treatise of this nature.

The monograph includes a discussion of dispersal in which the author stresses the importance of transport by aerial currents, and the book ends with a short chapter on the relative abundance of the spider population in the few localities which have been investigated.

The plates are well reproduced from excellent photographs and, although photography is not the ideal method of illustration, they will be a useful supplement in the identification of British spiders. Printing and production reach the high standard expected of Ray Society monographs, and Dr. Bristowe is to be complimented on a clear and readable style which is all too rare in scientific writings.

R. J. W.

An Account of the Genus Dioscorea in the East

Part 2: The Species which twine to the Right; with Addenda to Part 1, and a Summary. By D. Prain and I. H. Burkill. (Annals of the Royal Botanic Garden, Calcutta, Vol. 14, Part 2.) Pp. 425–528. (Alipore: Bengal Government Press, 1939.)

PART I of this monograph, reviewed in NATURE of January 29, 1938, dealt with the species of Dioscorea which twine to the left. The distribution of Part 2, treating of those that twine to the right, has been delayed, and under existing conditions this delay is indefinite. The portion of it now under review contains only the final summary and no systematy. In view of the delay in publication, advance separates of this summary have been obtained by the authors for presentation to institutions specially interested in biogeography. It presents thirty-five tables analysing in detail the distribution of the species described (147 in all) over the oriental range of the genus. A short but necessary discussion on "the meaning of the word species" defines the position adopted by the authors towards this vexed subject. It is followed by an exhaustive 'retrospect' in which is expounded an account of the systematic study and exploratory research devoted to the genus in the past, with particulars of the authors and collectors who have contributed to knowledge of the group. That there is still much to be elucidated is evident from thorough investigations under the title "Estimate of the Imperfection of Present Knowledge".

Finally, we have a dissertation on the biology of the species concerned, concluding with an exposition of the phytogeographic scheme adopted. To many botanists, especially on the ecological side, and to biologists generally, this part will prove more interesting and valuable than the mere systematy. It contains ample evidence in its pages of the enormous amount of labour and research put into the work.

It is to be hoped that workers in the group and area will not be for long deprived of the remaining portion.

An Architect of Nature

Being the Autobiography of Luther Burbank. With Biographical Sketch by Wilbur Hall. (Thinker's Library, No. 76.) Pp. xvii+139. (London: Watts and Co., 1939.) 1s. net.

IN this autobiography Luther Burbank reveals what proved to be the driving force behind his amazing life when he wrote "Darwin made important and absolutely new findings with regard to pollenization and fertilization, but, when he made them and set them down, he left it to others to make the rules useful". Burbank took it upon himself to be a pioneer among those "others", and now "every schoolboy knows" how he rapidly built up new species of plants by selecting with a knife, a hoe, or a spade and bonfire rather than by allowing new forms to develop more slowly under the deadly environmental competition of Nature.

In an introductory biographical sketch to this little volume, Wilbur Hall describes how Burbank had reached the age of seventy years before he felt constrained to express on paper the more important thoughts, observations and philosophical speculations of his life. This book represents all that he limned in his own words, so that one would expect it to remain a fount of delight to all who are interested in the man who was "blasphemed, preached about, talked at, written to, telegraphed, scolded, abused, and even vilified" merely because of his attempts to speed up Nature's methods by making use of keen and discerning man-made selective processes in the production of new types of plants. T. H. H.

On Miasmata and Contagia

By Jacob Henle. Translated by Dr. George Rosen. Pp. 77. (Baltimore, Md.: Johns Hopkins Press, 1938.) 1 dollar.

THIS important essay by one whom Garrison describes as the greatest German histologist and one of the greatest anatomists of all time, was originally published in 1840 in Henle's "Pathologische Untersuchungen", and contains the first clear statement that living organisms are the cause of contagious and infectious diseases. Dr. George Rosen, who has provided an excellent translation, points out that Henle's theory was not based on any personal experiments but on the data collected by his predecessors, such as Athanasius Kircher and Leeuwenhoek in the seventeenth century, who described infusoria and other microscopic animalcules, Wichmann who discovered the *Acarus scabiei*, Agostino Bassi who found that muscardine, an infectious disease of silkworms, was caused by a fungus, Cagniard de la Tour and Schwann, who showed that fermentation was due to yeast, and Schönlein, who discovered the parasitic cause of favus. Henle maintained that in infectious disease the morbid matter increased from the time that it entered the body, and that it must be organic in nature as only living organisms were able to do this. His view that the organism probably belonged to the plant kingdom was confirmed by Robert Koch, one of the most eminent of his pupils, more than thirty years later.

A Manual of Practical Anatomy

A Guide to the Dissection of the Human Body. B Prof. Thomas Walmsley. Second edition. In Parts. Part 2: The Thorax and Abdomen. P viii+331+7 plates. (London, New York an Toronto: Longmans, Green and Co., Ltd., 1939 12s. 6d. net.

THE principal changes in the new and great enlarged edition of this work, of which the fir appeared in 1921, are the introduction of fulle accounts of the examination of the living body, an especially of parts important in clinical practice, short description of the action of muscles and th changes in the form of parts when they function, th incorporation of numerous new figures and skiagram of the stomach, intestines and urinary tract, and change in the nomenclature to that adopted by th Anatomical Society of Great Britain and Ireland.

The book may be warmly recommended as a excellent practical guide for the dissector.

General Science Biology

By A. Spencer White. (Dent's Modern Scienc Series.) Pp. vii+243. (London: J. M. Dent an Sons, Ltd., 1939.) 2s. 3d.

THIS work has been prepared as a companio volume to the already published "Gener Science Physics" and "General Science Chemistry by the same author. The text is largely based o the reports of the teaching of general science compile by the Science Masters' Association, and is intende to cover the biology section of the general scienc syllabus of the School Certificate examinations. T material is presented in quite an interesting manne great prominence being given to experimental work The inclusion of subjects which would involve t use of the microscope is questionable, although u might be made of them as demonstrations. There an abundance of supplementary line-drawings, whi possess a diagrammatic clarity and simplicity th might usefully serve as a model for pupils.

Reminiscences of Country Life

By James George Cornish. Edited by Vaugh Cornish. Pp. xi+147+8 plates. (London: *Count Life*, Ltd., 1939.) 10s. 6d. net.

THESE reminiscences cover a period of sevent years of life in rural England—country parish in the counties of Suffolk, Berkshire and Devo Their author, James George Cornish, was born 1860 and died in 1938. Throughout his life, as the records bear witness, he was gifted with an observa eye for the life of the countryside and individu traits in the character of the countryman. H reminiscences have been edited by his brother, D Vaughan Cornish. As he points out, they derive inconsiderable value from the fact that they preser continuity over a very considerable period of tim This is especially interesting as in these years cruc changes took place in English agriculture a modes of country life.

CHEMISTRY

elins Handbuch der anorganischen Chemie

te vollig neu bearbeitete Auflage. Herausgegeben der Deutschen Chemischen Gesellschaft. System- omer 63 : Ruthenium. Pp. xxvi+124. (Berlin : lag Chemie, G.m.b.H., 1938.) 6.50 gold marks.

HE section on ruthenium in Gmelin's "Handbuch" contains an account of the physical and nical properties of this polyvalent element and ts compounds. The sources and preparation of metal are being dealt with in conjunction with r members of the platinum group. No fewer seven isotopes have been detected by the mass- troscope, and artificial radioactivity has been ted by bombardment with slow neutrons and erons. Ruthenium is very resistant to atmo- ric corrosion and the attack of strong acids, but an be oxidized in the presence of potassium rate to the tetroxide and by fused alkalis to enates.

uthenium is an excellent catalyst, particularly oxidations, being superior to platinum in this ect. A list of references to this application as lyst is given. It gives rise to a large number of plex co-ordination compounds, including a stable, tile carbonyl $Ru_2(CO)_9$, a red pentanitrosyl and y ammines and derivatives of organic bases. ong these complex compounds is the deeply ured derivative of tervalent ruthenium called henium red', which has the power of dyeing ural silk. Morgan and Burstall have shown that a chloro-hydroxo-tetrammine monochloride with rdination number 6. They have prepared from dichlorotetrammine monochloride, which reacts ammonia to regenerate ruthenium red. The stitution of this derivative seems to be uncertain, e Gleu and Breuel have recently described both and *trans*-dihalogenotetrammine halogenides, ch do not react with ammonia. A list of deriva- s of organic bases containing ruthenium is given.

sico-Chemical Experiments

Prof. Robert Livingston. Pp. xi+257. (New k : The Macmillan Company, 1939.) 10*s*.

HEORETICAL introductions to physical chemistry are plentiful—practical books on the e subject are only too rare. Dr. Livingston's pact and informative book arrives at an oppor- e period. Physical chemistry has now become so e a subject, and uses such specialized technique, t it becomes increasingly difficult to write a ctical book which will include a selection of eriments illustrating new principles with suffi- ntly modest and fool-proof apparatus.

n the volume under notice, classical physical mistry is there with all up-to-date improvements. re are, however, many welcome innovations in mall a book. For example, some experiments in ioactivity are described, absorption spectra find seful place ; there is a good discussion of, and a ple experiment with, a plate still. Chemical etics is represented by more interesting types of reaction than are customarily found in practical books. The section on electrochemistry is equally good. Even simple photochemical and colloidal experiments assume their proper place in the volume. But especial commendation must be accorded to the author for his excellent chapter on measurements, errors and computations. This is a chapter which may be read with great profit by advanced students of physical chemistry. This apparently modest little book, full of relevant information, therefore puts modern physical chemistry within the reach of any laboratory.

H. W. M.

Factual Tests in Inorganic Chemistry

(Post School Certificate Standard.) By F. A. Philbrick. Pp. 80. (London : G. Bell and Sons, Ltd., 1939.) 1*s*.

Answers to Factual Tests in Inorganic Chemistry

By F. A. Philbrick. Pp. 13. (London : G. Bell and Sons, Ltd., 1939.) 6*d*.

THIS book of "Factual Tests" is designed to test the student's grasp of inorganic chemistry up to Higher Certificate and Intermediate B.Sc. standard. Each question is set in such a way that the student has merely to select the correct answer from five alternatives and write down its number. Thus to answer : "34. The ammonium salt used in the Leclanché cell is the 1 sulphate, 2 chloride, 3 nitrate, 4 carbonate, 5 phosphate" ; the student merely writes down the figure 342.

The questions are set out in 'papers' which cover the chemistry of either one element or a group of related elements, and the numbering is devised so that all answers require a three-digit figure. The correct answers are supplied in a separate booklet, as recorded above.

There are clearly many advantages in having a book which can be used by student and teacher to test rapidly and objectively the factual information which has been acquired, without always having recourse to the wearisome tasks of writing out and correcting answers to the conventional type of question. In the opinion of the reviewer, "Factual Tests" should also have included questions which require a one- or two-word answer, but in spite of this omission it should prove of use to both students and teachers.

A. C. C.

A Course of Study in Chemical Principles

By Prof. Arthur A. Noyes and Prof. Miles S. Sherrill. Second edition, rewritten. Pp. xxv+554. (New York : The Macmillan Company, 1938.) 21*s*. net.

THE subject-matter has been thoroughly revised in the second edition of this book. A considerable improvement has been made by dealing with the first and second laws of thermodynamics at the beginning instead of at the end of the book. The kinetic theory has been considered in greater detail, and the essential features of the Debye-Hückel ion attraction theory have been added. The text, as in the old edition, is interspersed with problems which should prove of considerable value to university students.

ENGINEERING

Airplane Structures

By Prof. Alfred S. Niles and Prof. Joseph S. Newell. Vol. 1. Second edition. Pp. xv+451. Vol. 2. Second edition. Pp. viii+177. 13*s*. 6*d*. net. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1938.)

THE revised edition of this book, now expanded into two volumes, attacks the problem of aircraft structural design from the point of view of the designer who may wish to apply the advances that scientific thought have made available to his problem. It discusses all of the methods of design and analysis that have been used successfully, and by the use of illustrative examples endeavours to show the best uses and the limitations of each.

The introductory chapters are devoted to the aerodynamic questions from which the conception of the applied external loadings is derived, and although naturally not complete in their scientific discussions of these problems, they do define them sufficiently to make clear the loadings that the structural designer is called upon to resist. The bridging of this gap has been conspicuously absent from published works hitherto.

The main portion of Volume 1 is then devoted to the various accepted methods of structural analysis, with applications, and includes a chapter on the strengths of methods of joining structural elements together, such as are acceptable in the somewhat peculiar aircraft practice. A very useful chapter on deflection and stiffness treated as a design problem finishes off the first volume.

The second volume contains a discussion of indeterminate structures, and gives many excellently worked out examples occurring in aircraft problems. The treatment of stressed skin structures is the least satisfactory part of this work; but these are problems still in their infancy, and about which controversial views are necessarily held until the correct practices have been established by experience.

In general, it can be said that this is an excellent book for both students and designers. It contains an unusually large number of tables, charts, and such aids to routine design work not always found in textbooks; further, these are set out in a manner calculated to make them of greatest use to the practical designer.

Foundations and Earth Pressures

By C. Hyde Wollaston. Pp. 295. (London: Hutchinson's Scientific and Technical Publications, 1939.) 21*s*. net.

IN recent years, increasing attention has been given to investigation in that branch of science designated soil mechanics, which deals with the behaviour of soil when treated as a material of construction. An account has been given in the report of the Building Research Board of the advances made in this branch, and it is therefore of especial interest and value to have the views of an engineer as to the methods of putting into practice such information as is available. These have been expressed with clearness and a full force of conviction by C. Hyde Wollaston, late engineer in the Public Works Department of Bu His aim is to bring home to engineers the desirab and importance of treating soils as materials of struction and with the same attention as is give timber, steel, and concrete.

The author shows that soil mechanics provid far more reliable and certain guide than is gene supposed, and explains how soil testing should perly be conducted. A clay soil, hitherto the bug of engineers, need no longer be regarded with picion. Its 'water-content' is now known to b sure criterion of its strength against compression. the first part of the book foundations are dealt w and in the second part the author turns his atten to earth pressures and retaining walls. The pract application of the new ideas on these subject exhibited in some fifteen examples which consti the third part entitled "Designs and Calculatio Here are treated actual designs ranging from a sin column footing to a reinforced concrete retai wall and calculations of the stability of bridge p useful both to the student and the practitioner.

MATHEMATICS AND ASTRONOMY

The Theory of Functions

By Prof. E. C. Titchmarsh. Second edition. x+454. (London: Oxford University Press, 19 25*s*. net.

THE second edition of Prof. Titchmarsh's "Th of Functions" has been produced ph graphically from amended sheets of the first, w the transfer of the main account of the gam function to the chapter on analytic continuation the insertion at the end of the chapter on inte functions of two theorems on asymptotic values an introduction to the theory of meromorphic fu tions which will send the reader eagerly to Nevanlin The list of memoirs consulted is unchanged; the of books recommended is of a more useful kind tha the first edition, but in an epoch when every weak ing of international bonds is to be deplored, regret that anyone should decide to restrict suc list so far as possible to works in English; result in this case is that whereas in 1932 a tota 25 titles was composed of 16 in English, 11 French, 7 in German, and a translation, in 1 a total of 24 titles includes 19 in English and translations.

Page numbers have been preserved, at a co there is only one page between 255 and 265, this is numbered 256–64; on the other hand, 28 followed by seven pages numbered 284*a* to 284*g*, then odd numbers take the left hand and e numbers the right until a blank unnumbered p at the end of the chapter restores the usual locati Since references throughout are to sections, not pages, the economy seems petty.

The success which this book has achieved pro that Prof. Titchmarsh was right in anticipating th the collection which he describes too modestly consisting of "rather disconnected introductions us branches of the theory of functions" would service to students to whom the mass of existing ture appeared "rather formidable". It proves, that early reviewers were right in recognizing a ty of readability in his writing; in effect, the e given to students was: "This is a book from h you will be able to learn how to do mathe-cs", and we cannot do better than repeat this e with all the confidence that comes from ring that it has been endorsed by those best ted to discover that it was sound, namely, the ents who have followed it. E. H. N.

etary Co-ordinates for the Years 1940–60 referred e Equinox of 1950·0

ared by H.M. Nautical Almanac Office. Pp. 150. (London: H.M. Stationery Office, 1939.) 6d. net.

HE present work is a continuation of the previous volume published in 1933, which contained in ephemeral data up to 1940; it extends these 1940 to 1960. The general arrangement is the as in the first volume, but certain alterations been introduced which add considerably to the enience of the tables. As computing machines be used almost entirely in connexion with the , the logarithm of the radius vector has been ted and a column giving the Julian date has inserted.

ose who are engaged in the computation of tary perturbations will find a great convenience the method of arranging the planetary co-ates. The material for Venus and the Earth is ed on facing pages, and the same applies to er and Saturn, the ephemeris for the latter t being given for intervals of 10 days instead days as in the previous volume. The material ranus and Neptune is also printed on facing , intervals of 40 days being retained as before. attractions of the sun are given to an extra al, the last figure retained being the tenth al. This refinement is quite unnecessary for ts, but will have an important application in ase of the perturbations of minor planets. The Prof. Numerov and Dr. Bower outlined a scheme he computation of very accurate ephemerides rtain minor planets, from which systematic ctions to star places could be determined, the extra figure will serve a useful purpose

e first volume gave the spherical co-ordinates anus and Neptune from 1903 to 1940 at intervals 0 days, and the present volume includes these dinates from 1800 to 1903. Full details are of the application of Cowell's method for the utation of perturbations, Comet 1933*f* (Whipple) selected for the purpose. This particular part e work was done by Miss F. M. McBain under irection of the Superintendent. It is scarcely sary to add that the volume will be invaluable mputers in various branches of astronomical

M. D.

Astronomy

A Textbook for University and College Students. By Prof. Robert H. Baker. Second edition. Pp. xx+522. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1939.) 16s. net.

THE first edition of this work appeared in 1930 and the second edition in 1933. Two reprints of the later edition appeared in 1934 and 1935 and the present volume is a third reprint. While the book is excellent in many respects, it is regrettable that a third edition was not produced instead of a reprint. This would have brought it up to date and would have enhanced its value very much. As one instance of the necessity for a new edition, we may refer to the story of Galileo and the Leaning Tower of Pisa, repeated on p. 151. Prof. Lane Cooper has shown that there is no foundation for the story, and Prof. A. S. Eve, while not agreeing entirely with Cooper, nevertheless concludes that "definite historical evidence is lacking" (NATURE, 137, 8, Jan. 4, 1936). It is to be hoped that a new edition will be put in preparation. M. D.

MISCELLANY

Aequanimitas

With other Addresses to Medical Students, Nurses and Practitioners of Medicine. By Sir William Osler. Reprinted from the third edition. Biographical Note by Sir Walter Langdon-Brown. Pp. xiv+452. (London: H. K. Lewis and Co., Ltd., 1939.) 7s. 6d. net.

THIS book, which contains the best-known of Osler's minor writings, consists of twenty-two addresses, seventeen of which were delivered in various parts of the United States (New York, Boston, Philadelphia, New Haven and Baltimore) and five in Canada (Montreal and Toronto). The well-merited popularity of the work, of which the present edition contains a sympathetic preface by one whom Osler would have called his "brother Regius", is shown by the fact that three impressions were made of the first and nine of the second edition.

Though addressed primarily to medical practitioners and students, the work, owing to its cosmopolitan outlook, will appeal to a much wider circle of readers, especially at the present time. With a characteristic blend of ripe wisdom and playfulness, Osler discusses a great variety of subjects, such as the education of the medical student and post-graduate, the importance of foreign travel and avoidance of Chauvinism, the necessity of doing the day's work well and before the age of forty, and physic and physicians as depicted in Plato. A 'bed-side library' of books for medical students is appended, consisting of the Old and New Testament, Shakespeare, Montaigne, Plutarch's Lives, Marcus Aurelius, Epictetus, "Religio Medici", "Don Quixote", Emerson and Oliver Wendell Holmes' "Breakfast-Table Series".

A Bibliography of the Writings of Harvey Cushing

Prepared on the occasion of his Seventieth Birthday, April 8, 1939, by the Harvey Cushing Society. Pp. xv+108. (Springfield, Ill., and Baltimore, Md.: Charles C. Thomas; London: Baillière, Tindall and Cox, 1939.) 5 dollars.

THIS book, the sale of which is limited to four hundred copies, contains the bibliography of a man who was equally well known as an eminent brain surgeon and the author of one of the most successful biographies of recent times. The work, which is preceded by a sympathetic and humorous note by Dr. Arnold Klebs, the well-known medical historian, entitled "Bibliographia Animata", consists of four parts and appendixes. The first part gives a short account of Dr. Cushing's life, degrees and honours bestowed upon him by more than twenty different nations. In the second part are listed his books, thirteen in number, of which the best known are "The Pituitary Body and its Disorders" (1912), the "Life of Sir William Osler" (1925), and "Intracranial Tumours" (1932), of which a German translation appeared in 1935 and a French one in 1937. The third part contains a list of his addresses, papers in journals, and reports published between 1898 and 1938 numbering 306, while the fourth part is devoted to papers emanating from Dr. Cushing's clinics and laboratories.

The appendixes contain the names of his assistants in neurological surgery from 1908 to 1932 and voluntary graduate assistants from 1920 to 1932, hailing from England, France, Germany, Belgium, Holland, Rumania and Esthonia, and a list of members of the Harvey Cushing Society.

German–English Science Dictionary

For Students in the Agricultural, Biological and Physical Sciences. By Prof. Louis de Vries, with the collaboration of Members of the Graduate Faculty. Pp. x+473. (New York and London: McGraw-Hill Book Co., Inc., 1939.) 18s. net.

IT was Dr. Samuel Johnson who emphasized our indebtedness to the compilers of dictionaries when he wrote, "Every other author may aspire to praise, the lexicographer can only hope to escape reproach". Scientific men will indeed be grateful to Prof. de Vries for having brought together some half a million stock words which are representative of German scientific language. No attempt has been made to include all the names of animals, plants, chemical compounds, etc., since each subject would need a dictionary of its own. But since research in the various departments of science now extends into complicated inter-departmental problems, the author has included terms which enter into the chemical, physical and biological sciences. Further selection has made use of the fact that the compounding of words is such a characteristic feature of the German language, only sufficient basic information being included to permit of the building-up of composite words. The book is strongly and attractively bound, but still remains a very convenient size for purposes of frequent reference. T. H. H.

Physics

Cosmic Machinery in an Electro-Magnetic Univ

By Capt. H. A. Staples. Pp. vi+224. (Lonc William Clowes and Sons, Ltd., 1939.) 12s. 6d.

THE author of this work claims to have structed a magnetic machine which was ab produce motion 'similar to the motion of the and planetary bodies". As the sun rotates, field of radiation rotates with it, and this " sweep" is responsible for the forward motio the earth in its orbit. Capt. Staples state page 139 that, with reference to Kepler's T Law, "the reason for the application of the p of the cube in association with the power of square have [sic] remained obscure". Appare however, this obscurity disappears with his ele magnetic interpretation, planetary motions fa into line with the laws relating to wave m issuing from a radiant source. It is only neces to point out that there is nothing obscure a Kepler's Third Law, which is very easily der from the inverse square law. It may be added the electromagnetic field of the planets appea play an important part in their orbital mo according to the author, but he makes no att in this book to apply his theory to other bodi the solar system, such as meteor streams, comet even the minor planets. Quantitative results o motions of the satellites would have been usef verify or disprove the theory, but the figures explanations given on pp. 149–51 are too vag be applied.

Although the author has spent twenty yea research on his work, it will not yet be gene accepted. M.

Spontaneous Fluctuations of Voltage due to Brov Motions of Electricity, Shot Effect and Kin Phenomena

By E. B. Moullin. (Oxford Engineering Sc Series.) Pp. viii+252. (Oxford: Clarendon P London: Oxford University Press, 1938.) 17s net.

TO an engineer the result of the sponta fluctuation of voltage is a noise which is ge in his way, and which he calculates from for which give approximately the result he requires knows that he is up against a natural limitati what he wants to do. The author of the volume under review takes a novel view; he rather st the engineer by making the subject of philoso interest, and by showing that the physicist not know as much about the subject as the eng thought he did. The author does not think theory has caught up with the abundant e mental data, and he has done a remarkable serv collecting such information as is available in a able way, so that some super-mathematician m inspired to find a link between atomic data an nuisance being examined.

The text is produced with the care and c we have been led to expect from the Oxford Eng ing Science Series. L. E. C.

deterioration at a rate almost unknown in tem- rate latitudes. A single rainy season can com- tely destroy the fertility of a tropical soil unwisely posed.

il Destruction in Malaya

THE damage done to agricultural land by various rms of mining is considered by Sir Lewis L. Fermor his exhaustive "Report upon the Mining Industry of alaya" (Kuala Lumpor : Gov. Press, 1939. 6s.). The struction of land by the stacking of waste rock and ngue is small because the prevalent forms of tin- ning result in floods of water, heavily charged with t, either as coarse as sand or as fine as mud. This t, carried by the effluent water, chokes streams d causes flooding to such an extent that silt- tention schemes, necessitating dams or weirs, are ligatory. But much damage has been done in the st, and some is still being done, especially in the ning process of destroying hillside by water under draulic pressure. Again, the removal of the top yers of soil and their mixing with lower layers, ich is unavoidable in the process known as dredging, nder the whole surface within a mining concession fertile by the time the land is returned to agri- ltural use. Against these objections to mining must placed the fertilizing value on flooded land of a in deposit of silt. The writer is insistent that bber cultivation is equally harmful, in fact more , in ruining land by encouraging soil erosion and ding to the removal of fertile surface layers. Clean eding, a fetish of the rubber planter, causes soil moval between the rows of trees, and can be pre- nted only by the wise use of cover crops. Sir wis estimates that rubber cultivation has caused e addition of 33,000,000 tons of silt to the river stems since 1905, while tin-mining has contributed ly 16,000,000 tons. The debris from the rubber nds is both coarse and fine, and does more harm an the fine silt from the mines, some of which is rried to sea, and some of which fertilizes the land.

ewton's Letters

IN *Osiris* (7, 523–555; 1939) M. Jean Pelseneer, ose interest in the subject is well known, has produced some nine letters from Newton's un- blished correspondence. Four documents are own in reduced facsimile, and all are accompanied explanatory notes. The first four letters, between ewton and Oldenburg, are taken from the Ports- outh Collection in the University Library, Cam- idge. The next two, between Newton and Hooke, e in the Library of the Historical Society of Penn- lvania at Philadelphia. Of all these the main theme optical. Two other letters between Newton and ooke come from the Pierpont Morgan Library in w York; their subject-matter is of very minor terest. For the period covered by these eight letters 672–78) little original material bearing on Newton's e has been published. The ninth document is a int report signed by Newton and Halley on the rformance of a magnetic needle. This is an official per dated 1712, and preserved in the Public Record Office. It is two years since M. Pelseneer, writing in *Ciel et Terre*, pointed out with a reference to Stukeley's Memoirs of Sir Isaac Newton's Life, edited by A. H. White and then lately published, that the story of Newton and the apple certainly did not originate in the fertile imagination of Voltaire.

Early History of Antarctic Exploration

THE criticisms levelled by Prof. W. H. Hobbs at certain English explorers of West Antarctica of the early part of last century (*Trans. Amer. Phil. Soc.*, 31, Part 1, Jan. 1939) were discussed in NATURE of April 29, 1939, p. 731. A much fuller and a most scholarly treatment by Mr. A. R. Hinks of Prof. Hobbs's strictures appears in the *Geographical Journal* of October under the heading "On Some Misrepresentations of Antarctic History". The title indicates the nature of the conclusions which Mr. Hinks reaches. From a study of relevant documents, including original maps, he shows conclusively that Prof. Hobbs's claim that Palmer and not Bransfield discovered the Antarctic continent is false and that there is no foundation for Prof. Hobbs's contention that the chart signed by Bransfield which is in the Hydrographic Office is not genuine, and that Prof. Hobbs has no justification for discarding the account of Bransfield's voyage which appeared in the *Literary Gazette* (vol. 5, November 1821). No argument that Prof. Hobbs brings to this discussion can shake the authenticity of the documents on which Bransfield's claim to the discovery of Trinity Land, the first sighting of the Antarctic continent, is founded. Mr. Hinks raises many other points in his articles, including Prof. Hobbs's aspersions on the good faith of J. Weddell, whose discoveries conclusively stand the test of any inquiry and criticism. The article may be accepted as a final reasoned answer to the attacks made by Prof. Hobbs on these English navigators of Antarctic seas.

Germany's Oil Supplies

IN a carefully reasoned article published in the November issue of the *Industrial Chemist*, Dr. A. J. V. Underwood explains why in his opinion it is unlikely that Germany's belligerent activities will be suspended owing to shortage of oil. The present rate of production of oil and alternative fuels in the German Reich is estimated as 4,300,000 tons. This figure includes potential production of plants expected to be in operation by the end of this year. If plants which are likely to be in production by the end of 1940 or beginning of 1941 are included in the estimate, the potential rate of production of oil from all sources becomes 6,550,000 tons per year. In addition, imports of oil are at present available to Germany from Estonia, Rumania and the U.S.S.R. These with home-produced oil bring her total resources to 7,000,000 tons a year. If home production is increased as is anticipated, Germany will have access to 9,300,000 tons of oil a year. In 1938 Germany, including Czechoslovakia, consumed 7,900,000 tons of oil. This is substantially less than the 9,300,000 tons per annum potentially available, but has reference to peace-time conditions. In war-time, consumption by the fighting services will obviously increase even beyond the figure for 1938 when Germany was mobilizing, but at the same time civilian consumption will drop on account of the stringent rationing schemes now in force; also less oil will be used by Germany's mercantile marine, the activities of which have been so severely restricted of late. It is probable, therefore, that Germany's potential resources of oil will be sufficient for her war-time needs, and as reserves are available to supplement home production until such time as all projected plants are in operation, it is unlikely that she will go short of oil, unless through drastic changes in the international situation.

Folsom Man: Further Investigation in Colorado

A FURTHER season of excavation on the Lindenmeier site in northern Colorado has again failed to produce any trace of skeletal remains of Folsom man. Until such evidence is forthcoming, and on the assumption that it will afford some certain indication of the relation of the authors of the culture to the Amerindian peoples, the Folsom industry, with its distinctive characteristics, hangs in the air. The geological interpretation of the Folsom deposits on the Lindenmeier site assigns them to the last phase of the glacial period at an approximate dating of 12,000–25,000 years ago, and an association with an extinct fauna including mammoth, camel and extinct forms of bison. In the course of excavations carried out by Dr. F. H. H. Roberts, jun., in the past summer, the fifth season of his investigations on the site, it is reported in a statement issued by the Smithsonian Institution of Washington, that among animal bones, which had been chopped and split by man, was found the skull of an extinct bison measuring 36 inches between the tips of the horn cores—fully a foot wider than the spread between the horns in the modern species. In four months' work Dr. Roberts opened up a new section of the site over an area of some 45 ft. by 60 ft. to an average depth of six feet. His finds, in addition to the characteristic projectile points and previously known artefacts, included new forms of knives and scrapers, two to three times as large as those found before. A new feature in the culture is the bone bead, not hitherto found in Folsom deposits. Of those found here, one shows definite ornamentation in the form of a simple geometric design scratched on the surface.

Mental Hygiene in Old Age

IN a paper on this subject read before the Section on Care of the Aged, Welfare Council, New York City (*Mental Health*, 23, 257; 1939), Dr. George Lawton, psychological adviser to the Andrew Freedman Home, New York City, maintains that there is no group of persons whose mental welfare is more neglected than that of old people. This indifference, he declares, is world-wide even in countries with advanced social services. Although there has been for many years a guidance clinic for the aged in San Francisco, no definite steps have been taken f establishing a similar one in New York. Dr. Lawt asserts that what little knowledge we have of o people is based on pathological material, while v possess very little information about non-psychot old persons. He suggests that the psychologic difficulties presented by aged people should classified as follows: (1) the problems of neuroti borderline psychotic, psychotic, feeble-minded, a deterioriated individuals; (2) the minor mal-adju ments of fairly adequate old people caused by e cessive economic pressures and inhibitory soci attitudes; (3) the stresses and strains of perso undergoing normal mental and emotional declin According to Dr. Lawton, the management of t problem of senescence should include the followi measures, among others: (1) intensive, systemat studies over long periods of time, of the ment abilities, interests, recreations, emotions and perso alities of larger groups of men and women in to and country in each decade from forty to sixt (2) when such facts have been collected, guidan clinics should be set up to function in a simil manner to child guidance clinics; (3) courses geriatrics should be established in the medical scho to give future physicians a better understanding the effects of mental attitudes on the bodily ailmen of the aged.

Wild-life Restoration in the United States

IN the United States, as in other progress countries, the existence of many wild creatures h been threatened by the appropriation of lands f farming and industrial purposes, the destruction living places and breeding places, and the gradu disappearance of natural food and cover. To che this decrease of wild-life, the Federal Governme passed two years ago one of the most benefic measures of recent years, the Federal Aid to Wil life Restoration Act, briefly known as the Pittma Robertson Act of 1937. The co-operative schem which it envisages is one that might well be adopt in other countries, and a summary of its provisio and explanation of the co-operation which it see are now given by Albert M. Day (*U.S. Dept. Agr Misc. Pub.* No. 350; 1939). The Act recognizes t fundamental principle that wild-life is linked wi the land, and aims at the restoration of suitab environment in which wild birds and mammals m live and multiply. The Federal Government is willi to contribute materially towards this restorati programme, since it is known that individual Stat have been unable to cope with the situation becau of lack of funds. But a State to qualify for a sha of the grant—up to 75 per cent of the cost of wo performed on approved projects—must have pass laws for the conservation of wild-life, which sh include a prohibition against diverting fees paid hunters to any other purpose than the administrati of the State fish and game department. Already t Act appears to be working effectively. The gra total allocated for conservation projects in 19 was 1,186,666 dollars, of which State legislatur ntributed 296,666 and the Federal Government 0,000 dollars. Some time must elapse before the fect of these widely distributed schemes shows elf on the wild-life population, but there is every ason to think that the result will be gratifying to e naturalist as well as to the sportsman.

elevision Transmission over Telephone Cables

In the *Record* published in October by the Bell lephone Laboratories, Inc., L. Weis gives a helpful scussion of the problem of transmission signals over lephone cables. Most radio broadcasts originate in e studios of the broadcasting companies, and are ansmitted thence to the radio stations over high-ality programme circuits. Not infrequently the ick-up' point is at a distance from the studio and cuits to the studio must be provided over telephone ble pairs' not normally employed for broadcasting. ith television broadcasts such remote pick-up points e also required, but the utilization of ordinary teleone circuits to link them to the television studio more difficult because of the much wider band of quencies employed, besides certain exacting requireents for television transmission. Because of the perimental state of television broadcasting at the esent time, no arrangements for transmitting om these remote pick-up points have as yet been andardized.

Last May an experimental circuit of this nature as provided for the National Broadcasting Comny. More recently a somewhat similar one was ovided for the Columbia Broadcasting System. r ordinary telephone circuits a frequency band of out 3,000 cycles is sufficient, while for both these cent experiments the band extended from 45 to more an three million cycles—a range a thousand times eater than the voice band. When we consider the ses, we find that the loss in a co-axial cable at ree million cycles is only one millionth that in a ble-pair of equal length. For satisfactory television ansmission, equalizers must be provided to make e overall loss essentially the same for all frequencies. addition to the variation in loss with frequency ere is also a variation in the time of transmission. television transmission, if this is not kept extremely all the detail of the picture will be blurred, and urious transients and 'ghosts' will appear. Before cable pair can be used for television, it is necessary know the transmission time and then to provide ase equalizers to correct it. In the experiments e equalized line maintains the same transmission ne to within plus or minus one tenth of a microond, and this can be measured.

raffic Signals at 'Bank Complex'

A description is given in *Roads and Road Conuction* of November 1 of the 'electromatic' vehicle-tuated system operating on the 'flexible-progressive' stem. Automatic traffic signals outside the Bank England and on several important roads in the ality are to be installed as early as possible. It s been found that the signals in other parts of the City have proved of such value during the black-out that police officers have been able to concentrate on other important duties, and it is only at a few intersections that it has been necessary for them to control traffic by hand signals. The name 'Bank Complex' has been given to the area which is the junction of Threadneedle Street, Cornhill, Lombard Street, King William Street, Princes Street, Queen Victoria Street, Poultry and Mansion House Street. A specification for traffic signals to control the heavy and complicated traffic at this junction was prepared by the Ministry of Transport in collaboration with traffic officials of the City of London Police.

A scheme to meet the requirements of the specification was prepared by Automatic Telephone and Electric Co., Ltd., using electromatic vehicle-actuated signals. As traffic is approximately equally heavy in all directions, the problem is mainly concerned with ensuring the most rapid transit of vehicles through the thoroughfares converging on the area of the Bank Complex. Traffic increases to a maximum at morning and evening periods, and, if congestion and traffic blocks are to be avoided, the available road space must be used with the greatest efficiency. The whole system will be 'electromatic', operating on the flexible progressive system, under the control of a 'dual master-timer', and vehicle detectors will be used in each approach to the 'Bank Complex'. Signals are actuated by a special control unit divided into seven sections, which are linked together to coordinate the signal phases. It is important to notice that right-of-way is given to an approach only if there is a demand, and the length of this right-of-way period depends, up to a predetermined maximum, on the volume of the traffic. A novel feature of this system is provision of accommodation for traffic assessors in Cornhill and Poultry to determine the volume of traffic entering the complex on these approaches, so that variations of the right-of-way time can be made automatically.

The International Seismological Summary

The International Seismological Summary for October, November and December 1933 has just been received. It deals with 123 epicentres for earthquakes which occurred during that quarter, of which 47 were new epicentres and 76 repetitions of earthquakes from old epicentres, thus again confirming the knowledge that earthquakes tend to recur from the same epicentres. The five earthquakes with abnormal focus during the quarter all had deep foci. The first was on October 25, with epicentre in the Andes north-west of Jujuy (Argentine) with focus 0·03 of the earth's radius below normal. The second was on November 14 with epicentre north-east of Santiago on the borders of Chile and the Argentine with focal depth 0·02 of the earth's radius below normal. The third was on November 19 in the Pacific Ocean off the Japanese coast nearly south of Tokyo with focal depth 0·035 of the earth's radius below normal. The fourth and deepest was on December 1 with epicentre in the Pacific Ocean immediately to the south of the island of Aneityum (Loyalty Islands, Melanesia) with focus 0·09 of the earth's radius below normal. The fifth was on December 4 with epicentre in the Sea of Okhotsk to the east of Odomari with focus 0·040 of the earth's radius below normal. In continuation of the "Catalogue of Earthquakes 1925–1930", by Miss E. F. Bellamy, it has been decided to publish annually indexes to the International Seismological Summary. The first three of these for the years 1931, 1932 and 1933 arrived with the International Seismological Summary for the last quarter of 1933 and they form a very valuable addition to the summary for quick reference. The indexes are on a time basis, whereas Miss Bellamy's Catalogue 1913–1930 was on a geographical basis. The geographical basis is in many respects the better owing to the tendency mentioned above for earthquake shocks to recur from the same epicentre.

'Vibrated' Concrete

It is generally known that within certain limits the drier the concrete when it is mixed, the stronger it is when set. But it is not generally known, even among engineers, that it has been the practice for some years to contrive by mechanical means to produce super-compacted and hence super-strong concrete from materials which, treated in the normal way, would give normally strong results. A paper by R. F. Irving in the *House Journal of the Bournemouth Gas and Water Company* of October 2 gives the history and methods of manufacture of 'vibrated' concrete. In 1917, vibration of concrete was started in France on a commercial scale, and these machines have been extensively developed in America. Originally, the machines were driven by compressed air. The vibrating unit consisted of a freely moving piston, reciprocating as a shock producer, striking blows at a speed of 5,000–9,000 blows per minute. More modern machines, driven either by electric or petrol motors, have a rotor shaft provided with an unbalanced weight producing vibrations from 6,000 up to 21,000 per minute, the size of the motor unit varying from ½ to 1½ h.p. With the construction of No. 5 Reservoir at Alderney, the opportunity arose of taking advantage of the great developments in concrete construction. Preliminary tests of the relative strengths of unvibrated and vibrated concrete fully justified this procedure. Further, the vibration method led to a shortening of the time required for setting of the concrete and the consequent rapid release of the shuttering for use on new sections.

Earthquakes registered at Kew during October 1939

Fourteen earthquake shocks or earth tremors were registered on the seismographs at Kew during the month of October 1939. Four of these are reported to be very small, and some others have been confused by microseisms. The best seismograms obtained were for the earthquakes of October 10 and 17. That on October 10 had a probable epicentral distance of 88° from Kew and a depth of focus of 75 km. The earthquake of October 17 was again a deep focus shock, being thought provisionally from Kew records to have had a focal depth of abo 150 km. It was probably situated in the Ne Hebrides and was strong enough to give a f complement of pulses, including *ipPPP*, a lon tudinal body-wave reflected three times at t earth's surface, coming to the surface for the four time at Kew where it was registered.

Earth Tremor in New England

An earth tremor was felt on Tuesday nigh November 14, in the New England States of Pen sylvania, New Jersey, Maryland and Delaware. Th epicentre of the shock was probably very close Philadelphia, and in Baltimore pictures were knock off walls and furniture overturned, which indicat at this place a probable intensity of IV on t Rossi-Forel scale. Damage was not serious and the were no casualties. Although earth tremors are n unknown in New England, it is unusual to have o so strong as this. California and the western Stat are much more liable to shocks than the easte States.

Earthquakes in Central America and Canada

Using instrumental reports from Georgetow Fordham, Philadelphia, Weston and Guatemala, t United States Coast and Geodetic Survey in c operation with Science Service and the Jesuit Seism logical Association has determined the epicentre the earthquake of September 20, 1939, to be betwe Corquin and Ocotepeque on the mountainous bord between Honduras and Guatemala in Central Americ From readings of seismograms obtained at Pitt burg, Tucson, Ottawa, St. Louis and Fordham, t provisional epicentre of the earthquake of October 2 1939, has been determined to have been some twen miles south-west of Tadoussac in the Province Quebec. Both districts are liable to small eart quake shocks, though those in Central America a usually somewhat more intense than the Canadi shocks. Further news of these shocks is await from the observatories at Guatemala and Ottawa.

The Polarograph

Fifteen years ago Prof. J. Heyrovský, of the Char University of Prague, described a polarograph apparatus with the dropping mercury cathode whi he used for showing the presence of certain met in solution by the position of 'waves' produced the deposition potential curves automatically record as 'polarograms'. Since that time, Heyrovský a his co-workers have carried out many academ physico-chemical researches with the polarograp and in recent years it was beginning to find applic tion for other purposes in pure and applied scienc ranging from its use in examining sera for the diagno of cancer (Nature, 142, 316; 1938) to, say, t estimation of iodine in Chile saltpetre. The genui apparatus has hitherto been difficult to obtain, sin it was only made in Czechoslovakia, and resear workers and others will be interested to learn th although instruments are no longer obtainable fro Czechoslovakia, an improved model, complete wi f-contained recording equipment, of British design, ow being manufactured by the Cambridge Instru- nt Co., Ltd.; it is anticipated that the polaro- ph will find still wider uses in the near future, ecially in analytical and electrochemical work.

roleum

THE first number of *Petroleum*, a monthly magazine evoted to the essential interests and needs of the roleum industry", was published in October onard Hill, Ltd., 17 Stratford Place, London, W.1. nual subscription, 10*s*. post paid. Abroad, 12*s*. 6*d*.). e sponsors of this journal are to be congratulated launching this new venture scarcely a month after beginning of war, and on the way in which they ve interpreted the Prime Minister's admonition to ry on. Naturally the outbreak of war materially set carefully laid plans for the first number. ghly specialized articles had to be omitted and otographs discarded lest they should fall into my hands. Moreover, many potential contributors re called away on national service and were ordingly not in a position to submit articles. vertheless, in spite of these handicaps, the first mber is full of interest and it may be its lack of highly technical contributions will prove an asset the long run. The question raised as to whether ncrete or steel should be used for underground rage, the description of some lesser known uses petroleum and the notes on petrol rationing in eat Britain and other countries, to cite a few amples, should appeal not only to petroleum hnologists but equally to a far wider public.

tomology in South Africa

THE appearance of volume 2 (dated October 30, 39) of the *Journal of the Entomological Society of uth Africa* will be welcomed by workers in this nch of zoology. Some seventeen papers are in- ded within a compass of 262 pages and their great ersity of character may be gathered from the fact t they include descriptions of new Thysanoptera, tudy of body temperature in *Samia cecropia* and investigation of the chromosomes in some of the nsvaal Acrididæ. We wish every success to this periodical and trust that it will be assured of equate support during these critical times. The ce of the volume is £2, and European readers may tain it from N. V. Swets and Zeitlinger, Keizergracht , Amsterdam, Holland.

oks on Gardening and Botany

MESSRS. DULAU AND COMPANY, LTD., of 29 Dover eet, London, W.1, have issued a catalogue of books botany and gardening. Several volumes of ndard journals, many of which are out of print, offered, notably *Curtis's Botanical Magazine* 42), the R.H.S. Daffodil Year Book for 1913–15, first 22 volumes of the *Transactions of the Edin- gh Botanical Society*, the *Journal of Botany*, and *Kew Bulletin*. The remainder of the list covers better-known classics of a wide range of horti- tural activities. Seventeenth-century herbals appear to be represented mostly by later reprints, though one or two originals are also offered. A number of first editions and association books of general literary significance occupy the main part of the catalogue.

Centenary of Pulkovo Observatory

THE centenary of the Pulkovo Observatory, one of the oldest scientific institutions in the U.S.S.R., will be marked by a special jubilee session of the Academy of Sciences to be held in Leningrad on December 25. The papers of a scientific and historical character to be read at the session will show in historic retrospect the century of endeavour of the Pulkovo Observatory and its role in world science. The centenary will also be marked by the issue of a comprehensive symposium and the opening of an exhibition dealing with the work at the Observatory.

Announcements

PROF. E. D. ADRIAN, professor of physiology in the University of Cambridge, has been appointed a member of the Medical Research Council in the vacancy caused by the death of Prof. John Mellanby.

THE following officers for 1940 of the Institute of Metals have recently been elected: *President*, Lieut.-Colonel the Hon. R. M. Preston; *Vice-Presidents*, Dr. S. F. Dorey, Engineer Vice-Admiral Sir George Preece, Mr. A. J. G. Smout; *Honorary Treasurer*, Lieutenant-General Sir J. Ronald E. Charles.

THE Institution of Automobile Engineers is holding a special general meeting to which other institutes have been invited on December 12, at the Institution of Electrical Engineers, Victoria Embankment, W.C.2, at 6 p.m., when Dr. J. S. Clarke of the City of Birmingham Gas Department will read a paper entitled "The Use of Gas as a Fuel for Motor Vehicles".

THE Hunterian collection of surgical specimens at the Royal College of Surgeons of England has been removed to a bomb-proof vault in the College basement. All the more important manuscripts, books, and pictures in the College library have been moved to the country.

The Universities of Breslau, Erlangen, Marburg and, with the exception of the medical faculty, Königsberg, which were closed at the beginning of the war, have reopened.

PROF. GERMANO SOLLAZZO has been nominated director of the new hospital at Milan named Ospedale del Perdono, which is to take the place of the famous old Ospedale Maggiore.

THE second Argentine Congress of Ophthalmology will be held at Rosario in October 1940, under the presidency of Prof. Esteban Adrogué. Further information can be obtained from the Sociedad Argentina de Oftalmologia, Santa Fé, 1,171.

LETTERS TO THE EDITORS

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 911.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

An Inhibitor of Growth Extracted from Pea Leaves

RECENTLY, Stewart, Bergren and Redemann[1] and Stewart[2] have extracted from the leafy cotyledons of radish seedlings a substance which retards the growth of oat coleoptiles. They extracted by a method devised by van Overbeek[3] for extracting auxin, leaving the material in purified ether without grinding it up, and then drying the extract by distillation and evaporation; and they tested the extract on decapitated coleoptiles by Went's method. Since it is an interesting question how widely growth inhibitors may be distributed in plants, I have made extracts from various parts of pea seedlings by the same method. The dried extracts were dissolved in a few drops of water, slightly acidified with hydrochloric acid, and the solutions, at about *p*H 5·5, were tested by being taken up in little strips of blotting-paper, measuring 8 mm. × 2·5 mm., which were then applied to *intact* dark-grown oat coleoptiles, lengthwise along one of the narrow sides and reaching to the top. The strips stood on little ledges of vaseline placed to support them. As a rule the dried extract from each gram of fresh plant material, weighing about 11 mgm., was dissolved in one drop (50 cmm.) of water, and each drop of solution sufficed for three strips of paper and so for three coleoptiles.

The extracts made from mature pea leaves together with 3 or 4 cm. of stem to each leaf caused the coleoptiles to curve positively, that is, towards the side to which they were applied, showing that they retarded growth on that side. The curves were quite strong after 1 hour or less at about 19° C., and they usually increased up to 1½ or 2 hours and then diminished and sometimes reversed. They varied surprisingly in amount, but often reached 20° and sometimes 25° or 30°. Other tests showed that the curves could not be due to the *p*H or to the osmotic value of the solutions, so that they must have been due to an inhibiting substance or substances. The curves started close to the extreme tip and spread downwards very slowly, reaching a level 10–12 mm. below the tip, and 2–4 mm. below the base of the strip of paper, after 2–3 hours. So this inhibiting substance differs from that obtained by Stewart and others, which travelled much faster. It is not the same as the wound substance, which had no effect in the same test. Extract from stem alone caused no curves, so that the inhibitor is presumably contained in the mature leaves. Extracts from growing apical buds caused only few positive curves, or sometimes none. But they often caused negative curves which developed later and at a lower level, and may possibly have been due to auxin. Extracts from correlatively inhibited leafy lateral shoots caused positive curves, indicating inhibitor.

These results suggest the question whether this inhibitor is involved in correlative inhibition. If so, it should disappear after several days from decapitated disbudded shoots: for in such shoots a lateral bu if allowed to remain, grows out rapidly after abo 3 days, showing that inhibition has practically ceas But actually in some experiments (though not all) the leaves of such decapitated shoots were fou still to contain abundant inhibitor after from 4 t days. However, this objection is perhaps not qu conclusive.

The inhibitor when contained in the dried extr was found to be insoluble in dry ether. So it mu have diffused out from the etherized plant mater in the water which was present: for a little wa was, of course, introduced in the plant material its and also the ether used in the extraction was quite dry. Accordingly, in order to collect the wh of the inhibitor, the distilling flask was rinsed with 2 or 3 c.c. of water after the ether had be distilled off (at 60° C.): this water was added ju before the distillation.

Utilization of Carbohydrates in Leguminous Sy biosis

EXPERIMENTS carried out in this department dur the past summer may be of interest in connexi with a recent letter from Allison and his collaborato in which they conclude for field-grown legumino plants that the associated nodule bacteria consu only a relatively small proportion of plant carb hydrates in their respiration. In these experimen determinations have been made of the rate of evo tion of respiratory carbon dioxide from the r systems of two series of soya bean plants growing water culture (Crone's solution), one series (of fift plants) being nodulated, the other (of ten plan being kept free of infection by the nodule organi and supplied with sodium nitrate. During the det minations, which were made at the flowering st and at a temperature of 20°–21° C., air initially f of carbon dioxide was bubbled through the cult solution in which the root systems were growing a then passed into absorption towers containi standard baryta. For the nitrate plants the evoluti of carbon dioxide was of the order of 0·8 c.c. N.T.P.) per hour per gm. dry weight of root tissu Allison *et al.* report an average Q_{O_2} of 2·2 for detac root fragments, equivalent to an absorption of 2·2 of oxygen per hour per gm. dry weight. They u young roots only, whereas the figure of 0·8 c.c. an average for the whole root system: again, it bable that the Washington experiments were con- ted at a higher temperature.

From the results with the nodulated plants, it ears, assuming the respiration per gm. dry weight the root tissues of these plants to be similar to t of the nitrate plants, that the evolution of carbon xide from the nodules themselves was of the order 2·5 c.c. per hour per gm. dry weight.

In comparing this with the corresponding figure of given by Allison *et al.* for oxygen absorption by dules (detached), consideration must be given to sible differences of temperature and also to their ding that the respiratory quotient of nodules in is considerably above unity. Since in the Glasgow eriments the dry weights of roots and of nodules re as 2·8 : 1 in the nodulated plants, it appears t during a given time the total carbon dioxide lved from the nodules of a plant was slightly ater than that from the roots alone. If, as Allison d his co-workers conclude, the respiration of dules is partly anaerobic, it is possible that in these ticular plants the amount of carbohydrate utilized nodule respiration (presumably chiefly by the teria) exceeded appreciably that used by the roots mselves, though no doubt it was still small com- ed with the total carbohydrate synthesized by the nt. The dry weight of roots and tops together pared with that of the nodules was as 12 : 1; so far no figures have been obtained for the res- tion of the aerial organs of plants of this type. experiments will be continued.

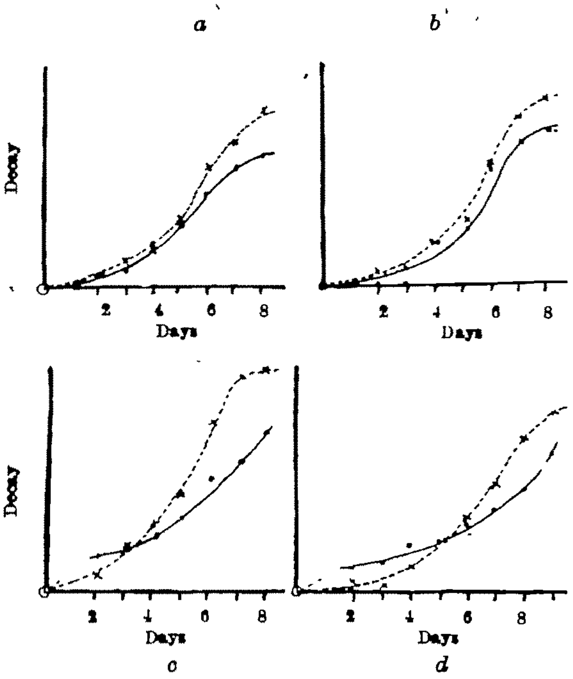
Humoral Immunity among Plants

PREVIOUS investigators[1,2] have concluded, after a nber of attempts to produce some measure of moral immunity in plants towards fungal and terial diseases, by various methods of 'vaccina- n', that there is no trustworthy evidence for any orted case of such immunity, despite earlier claims the contrary[3,4]. Manil[5], however, reports a very lized and temporary immunity produced in acco by vaccination with *Bact. tabacum*.

The principal reason why plants cannot be expected exhibit immunitary phenomena like those of the her animals is due to their lack of a circulatory tem, as pointed out by Chester[6]. For this reason, immunitary humour which may be formed in a t cell attacked by a parasite will probably be troyed on the death of this cell, unless it is able move out by diffusion beforehand into living ue ; but in the course of this process, the humour l become so diluted that any immunitary effect erved will be quantitatively much smaller, and s perhaps qualitatively different from those erto looked for.

In order to demonstrate such an effect, it would necessary to carry out experiments designed to ow the course of development of the post-parasite plex, and to compare this with the course of elopment of a suitable set of controls.

uch experiments have been performed by me at Station, using wheat seedlings as host plants, the rusts *Puccinia graminis tritici* and *P. rubigo- triticina* as parasites. Host leaves were inoculated the usual way, and two or three days later severed from the plant and the rust destroyed by placing them in a water bath at 40° C. for 15 minutes. They were afterwards inoculated with either the same, or the other, rust species, and kept under observation in plugged test-tubes for up to 10 days. In control tests, either the first or the second inoculation was omitted, or both, but the warm-water treatment was given in every case ; all possible combinations of the two rusts were used. All the host varieties used gave a fully susceptible reaction to both rusts.



COURSE OF DECAY, OBSERVED (FULL LINE) AND CALCULATED (DOTTED LINE) IN LEAVES CURED OF:

(*a*) *P. rubigo-vera* and re-inoculated with *P. graminis* ;
(*b*) *P. graminis* and re-inoculated with *P. rubigo-vera* ;
(*c*) *P. rubigo-vera*, and re-inoculated with the same ;
(*d*) *P. graminis*, and re-inoculated with the same.

In all graphs, ordinates represent degree of decay on an arbitrary scale, and abscissæ represent days from the application of the curative treatment.

The course of decay of the experimental leaves was followed by noting the degree of decay (that is, flecking, chlorosis, sporulation, withering, etc.) on an arbitrary ten-point scale. Observations were made daily, and the results plotted as the whole-line curves on the accompanying graphs. These are shown alongside the dotted curves, which were calculated by adding the two corresponding curves for the single-inoculation controls. Each point represents the mean of from six to twenty observations.

It will be seen that whereas the curves of decay of leaves inoculated and cured of one rust, and re-inoculated with the other (*a* and *b*), were nearly the same, both in form and magnitude, as the calculated curve, those for leaves re-inoculated with the same rust (*c* and *d*) were both retarded and enhanced relative to the calculated curves, and did not begin to bend over sigmoidally like the others within the space of eight days from treatment. This suggests that, whereas in the former case no appreciable interaction took place between the two dissimilar inoculations, in the latter the two like inoculations did so interact, and in view of the fact that the rust of the first inoculation was in every case completely destroyed by the curative treatment, this interaction was most probably due to the production of some specific humour by the first inoculated rust.

A full account of this work is to be published elsewhere in due course.

Heterosis in Lycopersicum Crosses in Relation to Seed Weight

In a recent communication Ashby[1] has criticized certain conclusions which I have drawn from an experiment[2] dealing with the problem of heterosis in Lycopersicum crosses. It was shown in this experiment that, in general, there is little correspondence between the presence of heterosis, measured as increase in fresh weight, in the seed and in the mature hybrid 145 days after sowing, and various possible reasons for this were discussed. Ashby suggests that there is another possible explanation which has been overlooked, namely, that correlations between seed weight and 'final weight' had been destroyed by the process of transplantation which took place in the 47th day after sowing, and he produces evidence to support this possibility. This evidence is in itself of great interest, but I consider that it in no way invalidates my conclusions, for the following reasons:

(1) My published data show that any correlations which might have existed between seed weight and weight of plant had already disappeared before transplantation took place (r between seed weight and dry weight of plant on 29th day $= -0\cdot160 \pm 0\cdot236$). Evidently this lack of correlation must be due to causes other than transplantation.

(2) In spite of marked differences in growth-rate between certain lines there is still a significant correlation ($r = 0\cdot488 \pm 0\cdot160$) between the dry weight of the plants before transplanting (29th day) and fresh weight after transplanting (145th day), so that, in this experiment, correlations were not destroyed by the process of moving the plants from pots in the greenhouse to a bed in the garden.

The problem of the relationship between seed or embryo weight and the size of the plant after a given period of growth is evidently a complex one, the full elucidation of which must await the accumulation of further experimental evidence. Investigations along these lines are at present in progress.

A Light-sensitive Strain of *Pseudomonas ærugin*

A strain of *Pseudomonas aeruginosa* (*B*
pyocyaneum), isolated from a milk factory efflue
was found to be affected by daylight in two differ-
ways. In the first place, the formation of pyocya
in young cultures was diminished in daylight. C
tures on a glycerol-peptone agar[1], grown at ro
temperature in the dark, developed an intense b
colour in two weeks (Ridgway's Dark Delft Blu
while parallel cultures in a north window showe
transient green colour (Russian Green) one week af
inoculation but had faded to a dirty green-bro
by the second week. Growth was apparently equa
good in both sets of cultures.

The second effect of light was to cause a mar
acceleration in the appearance of a red-brown col-
in old cultures. *Ps. aeruginosa* cultures kept c
tinuously in the dark undergo an almost impercepti
and very slow colour change from dark blue thro
plum colour to dark brown, which takes ab-
eight weeks to complete at 20° C. But dark-gro-
fortnight-old blue cultures changed to dull brown
a week, and to bright red-brown (Russet) in a fc
night, when kept in a north window. This ra
change of colour in daylight was also observed
cultures killed with formalin.

The view that the red-brown pigment in old cultu-
of *Ps. aeruginosa* is an oxidation product of pyocyar
is supported by the fact that, when blue cultu-
were exposed to daylight inside an anaerobic chaml
fading was seen, but no change to red-brown
visible in two weeks.

The red-brown pigment is therefore an oxidat
product of pyocyanin; its formation is accelera
by daylight, and is independent of the presence
living bacteria.

Influence of Age upon the Requirement of Vitami

During the course of experiments in which r
were given graded amounts of vitamin A, it v
noticed that by 50 days the incisor teeth of anim
on daily doses of from ¼ to 1 I.U. had lost the d-
orange pigment in the enamel, the teeth of anim
receiving larger doses being at this stage norm
But, if these latter rats were allowed to live long
it was found that daily doses of 2–3 I.U. of vitamin
which were adequate to produce normal teeth
50 days, appeared insufficient when the animals w
older, since later their teeth also gradually lost th
pigment. It was therefore decided to investig
this point more closely and to examine the te-
histologically.

The changes in the rat's incisor tooth in vitami
deficiency have been already described by Wolb-
and Howe[1]. The earliest effect is upon the odon-
blasts, which show irregular downgrowths into
dentin, leading ultimately to the complete disappe
ance of predentin. In advanced cases the odon
blasts show marked atrophic changes or disapp-
completely. This is particularly marked on the ling
side of the tooth, where in extreme cases the format
of dentin completely ceases and the odontoblasts
entirely lacking. As a result of the continued grov
of dentin on the labial side, the pulp cavity is pusl

one side of the tooth, and the pulpal slit at the ›tal end is displaced to the lingual side in a most riking manner. This inequality of dentin growth vitamin A deficiency has also been noted by hour, Smith and Hoffman[2]. Islets of osteoid tissue ıy be found in the pulp. In early stages the enamel gan appears relatively normal but later a progressive rophy is seen. The epithelium becomes flatter and e epithelial papillæ shrink, and in extreme cases e entire structure is replaced by a fibrous band which epithelial papillæ occur irregularly.

Groups of animals consisting of litter mates were t on our vitamin A-free diet (Irving and Richards[3]) weaning (23 days) and given dosages of vitamin A rying from ¼ to 3 I.U. daily. They were killed different ages and their teeth examined. An bitrary scale given in the accompanying table was ıployed for assessing the degree of histological normality found.

)EGREE OF SEVERITY OF CHANGES IN THE TEETH OF RATS ON VARYING DOSES OF VITAMIN A

Days on diet	Daily dose of Vitamin A (I.U.)						
	0	¼	½	1	1½	2	3
28	0	—	—	—	—	—	—
38	1	—	—	—	—	—	—
42	2	—	—	—	—	—	—
49	2,2*	1	?1	0	0	0	0
52	2,1*	2	1	1	1	1	0
54	1	—	—	—	—	—	—
66	2	1	1	0	0	0	—
119	—	—	—	4	—	—	—
148	—	—	—	4	—	—	—
180	—	—	—	—	4	4,3*	1,1*

he severity of the lesions is indicated by a number according to following scheme: 0, normal; 1, slight changes in the odontoblasts dentin; 2, marked changes in the odontoblasts and dentin; 3, formation of dentin on the labial side togrther with the previous ages; 4, atrophy of the enamel organ together with the previous ages. * Two animals.

In this experiment more particular notice was taken the changes in tooth colour. It was found in neral that by 66 days on the diet, the teeth of › negative controls were quite white and those of s getting ¼ and ½ I.U. were very pale yellow. higher doses the colour became gradually deeper d the 3 I.U. dose gave teeth almost normal in pearance. When the animals were allowed to live ger, the teeth of rats on the higher dosages like- e faded in a progressive manner. After 105 days the diet, the teeth of animals getting 1 and 1½ I.U. re quite white; after 135 days, those of rats ting 2 I.U. were completely colourless, and by) days those of rats getting 3 I.U. had only a faint low tinge.

The degree of histological change at different dosage els and times is shown in the table. It will be ted that the negative controls showed the first normal signs after 38 days on the diet. The changes worse with time but the animals died before very rked effects could occur, the longest survival on › vitamin A-free diet being 66 days. In two groups animals killed and examined after 49 and 66 days the diet, slight changes were seen in rats on ¼ and .U. daily, but the teeth of rats on the higher levels re normal. In a group killed at 52 days, the teeth wed changes up to an intake of 2 I.U. daily, .U. being adequate.

In comparison with these, a group of animals itinued longer on the experiment showed very vanced changes in the teeth. Two rats each re-ving 1 I.U. daily died after 119 and 148 days pectively and both showed extreme changes in the th. The other animals were killed after 180 days. Those getting 1½ and 2 I.U. daily showed very marked changes and even those getting 3 I.U. had teeth not entirely normal.

It should be noted that the time taken for the incisor tooth to be replaced by continual growth is about 40 days, so that the changes found in the teeth of all rats save the first listed occurred in teeth entirely formed while the animals were on the deficient diet.

The post-mortem findings in these animals followed in a striking manner the teeth changes. Of animals killed up to 66 days on the deficient diet, the negative controls showed the usual pathological changes such as keratosis of the stomach, and the improvement induced by even the smallest dose of vitamin A was very marked. Of the animals killed after 49 and 66 days on the diet, those getting 1 or more I.U. per day were quite free of pathological change; of those killed after 52 days, all showed some slight abnormality save the one getting 3 I.U. All the animals allowed to survive to later times had keratosis of the stomach, and several had this change in the bladder as well. This was most extreme in those getting 1 and 1½ I.U., was still present in marked amount in those getting 2 I.U. and was found in some degree even in those getting 3 I.U.

It appears from these results that the requirement of the animal for vitamin A increases with age, not only for tooth formation, but also to avert the other pathological changes associated with vitamin A deficiency. This is in somewhat surprising contrast with the requirements of other dietary factors, such as calcium and phosphorus, which are not supposed to increase in this manner. Guilbert and Hart[4] have suggested that the requirements of vitamin A are a function of the body weight, and our results would seem to confirm this.

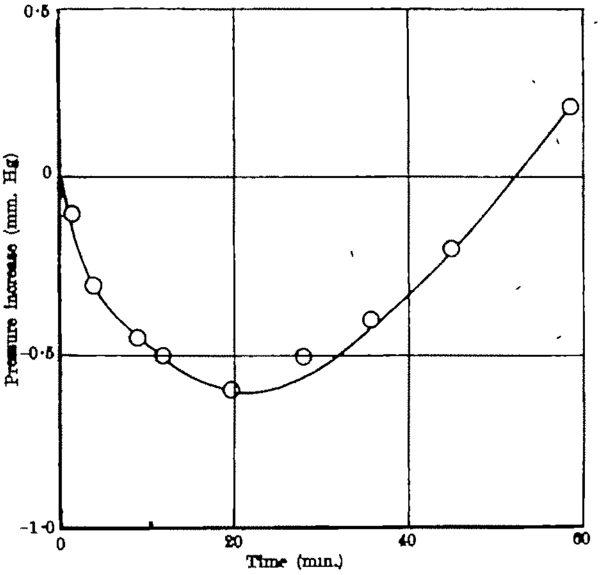
Thermal Decomposition of Acetone

THERE has been much discussion and experiment about the question whether the thermal decomposition of various organic vapours under prescribed conditions occurs predominantly by way of free radicals or not. For the decomposition of acetone in a reaction of measurable rate in the neighbourhood of 500°–630°, all the existing evidence is against the radical mechanism, except that advanced by A. O. Allen[1], who found that on reducing the reaction temperature to 462° an 'induction period' was observable. He regarded this as evidence for the existence of chains which required time to develop.

Quite apart from the fact that the time taken to establish the stationary state in a radical chain reaction of the kind postulated for acetone would be expected to be immeasurably small, it seems that the experimental evidence may have a very different interpretation. The length of the 'induction period' corresponds to the time normally required for a fraction of one per cent only of the acetone to decompose: and any abnormal pressure changes during this time are in all probability due to secondary causes, since we find that instead of a simple delay in the pressure increase (the 'induction period') there may equally well be an actual *decrease* in pressure.



This is shown by the accompanying graph, which refers to an experiment with 300 mm. acetone in a 250 c.c. silica bulb at 460° C. Such a decrease cannot be due to a simple delay in the development of chains. It must be due to some cause such as an adsorption effect or to initial polymerization of ketene formed from the acetone. This possibility being recognized, the phenomenon observed by Allen, and in the modified form by ourselves, is too uncertain to weigh against other evidence, and on too small a scale to have influenced any of the rate determinations made at the higher temperatures.

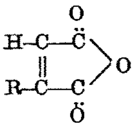
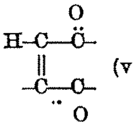
A Colour Reaction of Maleic Anhydride, *p*-Benzoquinone and their Partially Substituted Derivatives

When a trace of maleic anhydride (I) is added at room temperature to a colourless solution of triphenylphosphine (P Ph_3) in chloroform or benzene (for example, 1 drop of 1 per cent maleic anhydride solution to 1 c.c. of a 1 per cent solution of triphenylphosphine), a permanent orange-red colour is produced immediately.

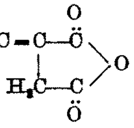
The same effect is observed with *mono*substituted derivatives of maleic anhydride, for example, citraconic (II), monochloromaleic (III), and *cis*-aconitic (IV) anhydrides:

R = H– (I), R = CH_3– (II), R = Cl– (III),
R = HOOC.CH_2– (IV. m.p. 74°)

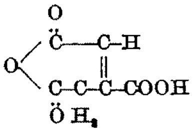




(V)



(VI)



(VII)

On the other hand, no colour is developed wi *di*substituted derivatives, for example, dimethy diphenyl- and diacetoxy-maleic anhydride. Male acid, its dimethyl ester, succinic anhydride and *tran* aconitic anhydride (VII. m.p. 134–135° C.) fail give this reaction; but the phenomenon is show by *p*-benzoquinone and those of its derivatives which not all the hydrogen atoms are substitute for example, 2 : 6-dichloroquinone and thymoquino (2-methyl-5-*iso*propyl-*p*-benzoquinone).

It seems, so far as it could be ascertained, that th colour reaction is characteristic of the grouping (when forming a part of the above-mentioned ri systems. The observation that the solution of itacon anhydride (VI) gave the colour reaction positive co be explained by the known fact that in solution isomerizes to (II).

Amongst the various substances investigated whi gave no colour reaction, we may mention anthr quinone, 2 : 3-dichloronaphthoquinone, phenanthr quinone and 2 : 6-dimethylpyrone.

Difference in Odour of *d*-, *l*- and *dl*-Derivatives Amino- and Bisamino-Methylenecamphors

It is well known that optically active isome despite the fact that they are identical in structu differ from one another in those physical properti which are of the directional (vectorial) nature, su as, for example, direction of rotation of the plane polarized light, unsymmetrical distribution of t hemihedral facets in their crystal forms, etc. T magnitude of these vectorial properties is, howev identical for the enantiomorphous forms. T optically active forms differ also in other respec namely, in their action on micro-organisms, enzym and in their physiological behaviour towards high organisms. In 1886 Piutti[1] observed that *d*-asparagi had a sweet taste, whereas the naturally occurri *l*-asparagine was insipid. Cushny[2] found th *l*-hyoscyamine was twice as powerful in paralysi the vagus as the racemic form, atropine, while t *d*-form was twenty times weaker in this action. O of the most striking examples of different phys logical activity recently observed is vitamin C ascorbic acid[3]: the dextro-rotatory acid is acti the lævo-rotatory form being physiologically inacti

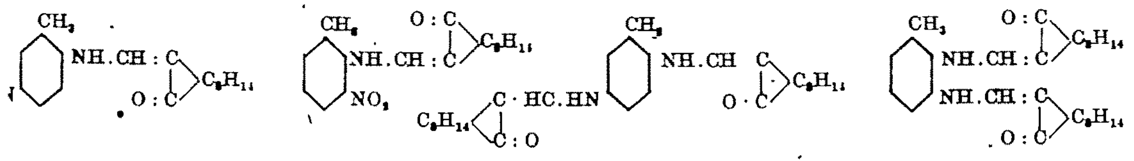
These differences in the physiological action of t optical antimers and their racemic forms are al associated with other properties, such as odo J. von Braun[4] has observed a few cases in which noted differences in odours not only among t optically active forms, but also in their inacti isomerides. The object of this communication is record differences in the intensity of odour of seve new derivatives of amino- and bisamino-methyler camphors in their *d*-, *l*- and *dl*-forms. The odour w

Name of the compound	Order of intensity of odour	Number o observer
5.nitro-*o*-toluidinomethylenecamphors. (I)	*l*>*dl*>*d*	10
3.nitro-*o*-toluidinomethylenecamphors. (II)	*l*>*dl*>*d*	13
2 : 5-toluylene bisamino methylenecamphors. (III)	*l*>*dl*>*d*	11
2 · 3-toluylene bisamino methylenecamphors. (IV)	*l*>*dl*>*d*	11

ved by different observers independently, and st invariably the order of the intensity of odour ticed by them was $l > dl > d$ in the four series of ers. These results are summarized in the above.

react differently towards the right- and left-handed forms of physiologically active isomerides.

Porter[6] was able to effect separation of racemic dyestuffs into their optically active components by differential adsorption of one of the isomers by wool.



I II III IV

e colour and odour of 3.nitro-o-toluidinomethyl-dl-camphor resemble those of saffron; the rs of the optically active isomers of this substance ell as of the remaining compounds in the table e have not been identified with that of any n substance. The odours are, however, pleasant. e position of the nitro group in the nitro-o-dinomethylenecamphors has a marked effect on intensity of their odours: the odours of these ounds, which are dyes with the nitro-group in 3-position, are more intense than those of the sponding forms with the nitro-group in the ition.

veral hypotheses have been put forward to unt for the different physiological activities of ptically active compounds. Pasteur[5] explained differences in action by supposing that the -substances and the tissue-substances of the als are themselves asymmetric. They therefore

King[7], arguing from these observations, attributed the difference in the physiological action of optically active forms to physical rather than chemical causes.

A fuller account of this work will appear elsewhere.

Points from Foregoing Letters

Snow has extracted from leaves of pea plants d in ether a water-soluble substance which its the growth of oat coleoptiles.

comparing the evolution of carbon dioxide from root systems of nodulated and nodule-free, te-fed soya bean plants growing in water culture, ond concludes that the amount of carbon dioxide uced by the nodules of a plant of the former type slightly greater than that from the roots alone. other workers have concluded, the respiration of les is partly anaerobic in nature, then it is possible in these water-culture plants the amount of hydrate utilized in nodule (presumably chiefly rial) respiration exceeded appreciably that used e roots themselves.

F. Parker-Rhodes describes experiments from h it appears that some degree of acquired resist- can be demonstrated in wheat plants against two e Puccinia rusts. This acquired resistance shows in an enhancement and a delay of the course cay of cut leaves infected with the rusts, cured eir infection, and reinoculated, as compared suitable controls. The magnitude of the effect wever, small.

C. Luckwill observes that in a series of pure lines F_1 hybrids of Lycopersicum correlation between weight and plant weight had disappeared by the day, but points out that this lack of correlation not due, as Ashby had suggested, to trans- ation, because this did not take place until 7th day.

Jane Meiklejohn describes a strain of *Pseudomonas aeruginosa* which forms less pyocyanin in daylight than in the dark. Light also accelerates the oxidation of pyocyanin to a red-brown pigment.

Small doses of vitamin A which are adequate to keep rats free from pathological change at early stages of the deficiency are not sufficient for this purpose as they grow older. It is inferred by J. T. Irving and M. B. Richards that the requirement of vitamin A increases with age.

The evidence, based upon certain abnormal pressure changes observed in the initial stages at low temperatures, that the thermal decomposition of acetone is a chain reaction is called in question by J. G. Davoud and C. N. Hinshelwood. Fresh evidence indicates that the effects are of a secondary nature.

A. Schönberg and A. F. A. Ismail describe a colour reaction between maleic anhydride and triphenylphosphine. The same effect is observed with mono- but not with di-substituted derivatives of maleic anhydride. The phenomenon is shown by *p*-benzoquinone and those of its derivatives in which not all the hydrogen atoms are substituted.

The intensity of odour of the optically active forms of several new derivatives of amino- and bisamino-methylenecamphors has been examined by Bawa Kartar Singh and Awadh Behari Lal. They find in each series that the lævo form has the most intense odour, followed by the racemic and dextro forms, in that order.

RESEARCH ITEMS

Early Islamic Decorative Technique

The first occasion on which it has been possible to analyse early Islamic niello is recorded in connexion with a group of objects in the precious metals said to have been dug up at Nihavand, a city of Persian Iraq, by Mr. Basil Gray (*Brit. Mus. Quarterly*, 13, 3; 1939). The group in question has recently been acquired by the British Museum, (Bloomsbury). Apart from its value as an addition to the collections, its importance is the greater because of the extreme scarcity of objects with precious metals from Islamic lands, where there are no tomb burials, and successive invasions caused widespread destruction. The find consisted of forty pieces, of which thirty-nine are of silver, nearly all enriched with gilding and niello, while one, the most considerable in size, is of gold. This latter is a wine bowl decorated with engraved roundels and an inscription in Arabic around the outside of the lip. Among the silver pieces are two series of plates which formerly decorated leather belts, two beads, a small circular plaque, a butt of a halberd possibly, and four other inscribed objects, as well as some fragments of buckles. The style unmistakably points to the Seljuk period. Epigraphic and stylistic evidence alike suggest the latter part of the twelfth century. Dr. Plenderleith reports after examination that there are microscopic particles of white metal embedded in the gold of the bowl; no iron is present and the particles are non-magnetic. They are extremely hard and there is good reason to regard them as iridium. Spectrographic examination of the niello indicates the presence of copper, silver, gold, tin, lead, with traces of aluminium, potassium, magnesium and boron. Analysis of filling taken from one of the small fragments of silver reveals the presence also of sulphur. The composition of this niello is, therefore, probably the same as Western niello, in antiquity according to Pliny, in the Renaissance period according to Cellini.

Cattle and Marriage among Southern Bantu

Among the Lovedu of the north-eastern Transvaal marriage, being patrilocal, involves, as among other Southern Bantu tribes, the transfer of *munywalo*. The nature of this institution has been analysed by J. D. Krige (*Africa*, 12, 4; 1939), who points out that the various interpretations in which it is regarded as the legalization of marriage, as a guarantee of a wife's status or good behaviour, and in terms of compensation, economic or ritual, are in the nature of parodies. To discover the real place of *munywalo* in the social system, it is necessary to appreciate the relation of the cattle exchanges to the social structure, as cattle constitute the essence of *munywalo* and the exchanges are the most important use to which cattle are put. The people do not rely on cattle raising. Milk is not used at all; the meat of cattle which die is much appreciated as a relish; the skins are used or discarded indifferently. Ploughing has added to the uses of the cattle, but social values centre in agricultural productivity rather than the role of cattle in contributing to this result. Cattle constitute no great standard of the kind of affluence that is important, this being based on maize. It is hidden rather than displayed, and gives no man the privil of rank. Yet like other Bantu tribes, the Lov have a strong emotional attachment to their ca though they are not regarded as sacred. Neverthe they are not sold or slaughtered, though there i taboo against it. This is neither economic nor economic, but *sui generis*. The chief functio cattle is in *nywalo* exchange, which accounts more than 95 per cent of all transfers of cattle, only other occasion being when judgment debts paid. There are about 330 marriages each year which the theoretical minimum number of c needed is about 2,600—only 400 short of the in the society. A distinction is drawn between c which have become involved in *munywalo* exch and those which are unencumbered. Thus a 87 per cent of the cattle are held in a chain of ri and restrictions which the temporary owner ca ignore. The exchange conditions, and is conditi by, two main social arrangements, cross-c marriage, and the allocation of a sister's *munywa* her brother. Hence arise series of cattle linkage which social groups, originally unrelated, are b together in a close network of social interests responsibilities.

Increased Mutation due to Hybridization

Hybridization leads to increased variability the mechanical recombination of genes present i parents, followed by segregation. A. H. Sturte (*Proc. Nat. Acad. Sci.*, 25, 308–310; 1939) has sh that inter-racial hybridization also may lead t increased mutation rate. By crossing marked *A* and *B* of *Drosophila pseudoobscura* and b crossing to race *A* or race *B*, he found that a 8·5 per cent lethal and about 0·5 per cent sex-li visible mutations were obtained. This is a n higher mutation frequency than usually foun intra-racial crosses, and has important implica regarding the evolution of new forms.

Development of Wings in Drosophila

C. H. Waddington (*Proc. Nat. Acad. Sci.*, 299–307; 1939) has made a study of the develop of the wings of normal and mutant Drosophil order to investigate the times and modes of effe different genes upon wing formation. The no wing expands rapidly until about seventeen h after pupation. At about twenty hours, contra takes place from the periphery inwards, and veins make their appearance first as broad b which rapidly narrow. At about twenty-five h the wing is a thin blade, and at forty hours the is fully formed and hairs appear. This defin wing stage is followed by folding accompanied second expansion. At emergence, drying out o wing leads to the second contraction and obliter in the internal structures. The effects of twenty genes affecting the wings were studied. These r to shape, size, vein breakage and additions, bli and wing-curvature. The first visible effect of is seen in the prepupal stage (*dy* and *m*), whil visible effect of others is not seen until unfoldi the young imago.

Oriental Peach Moth in Australia

oriental peach moth (*Cydia molesta*) has d serious damage to the fruit industry of the burn Valley, Victoria, during the past few years. tations which had occurred in this region for y years had been attributed to the codling moth *ia pomonella*) whereas, in so far as peaches are erned, the most damage was caused by *C. ta*. The degree of infestation varies seasonally, in 1933–34 this insect caused damage to orchard- amounting to about £70,000. The losses are iently serious to threaten the canning industry to call for a thorough study of the problem. H. Helson, of the Commonwealth Division of omic Entomology, gives an account of the lem in Pamphlet No. 88 (1939) of the Council cientific and Industrial Research for Australia. ppears that little good can be expected from ing as a method of control, and this has caused attention to be concentrated on biological means pression. Nine species of parasites are known to imary agents attacking the insect in Australia. hese the chalcid wasp *Dibrachys boucheanus* is nost effective: it parasitizes larvæ up to ninety ent at the latter end of the season. Since this t sufficient to ensure an economic degree of rol of the oriental peach moth, it was considered the introduction of parasites attacking the spring summer generations of this insect might prove ntageous. The result has been that four species rval parasites and one species of egg parasite introduced into Australia during 1935–38. veries made in the field show that the Braconid *ocentrus ancylivorus* is the most promising of parasites, and it is proposed to make further ductions of this insect.

rhinum Rust

RUST disease of the antirrhinum made a lightning nt upon Great Britain in 1934, but has not troubled our gardens. The causal fungus, *inia Antirrhini*, appeared in Egypt in 1936, how- and as it has since occurred rather frequently, Amin Fikry has made a study of the malady its control (*Min. Agric. Egypt, Tech. and Sci. ice Bull.*, No. 223. Govt. Press, Bulaq, Cairo, . P.T.4). Many interesting features of the se which were not apparent in the temperate te of Great Britain are described for Egypt. ications of various sulphur fungicides made at vals of two or three weeks, for example, can ol the disease most effectively, and it appears the beneficial effect of this treatment is de- ent upon a temperature higher than 22° C. All ties grown in Egypt appear to be susceptible e disease, and teleutosori have even been found he roots of some plants. Larvæ of species of lomyidæ were obtained from the rust pustules, do not appear to diminish the effects of the us. Several plates illustrate this account of the se, which also contains good descriptions of the us symptoms, and a short summary of previous ledge about the malady.

e Canker

canker disease of apple trees is still a very us malady. It is caused by the fungus *Nectria ena*, and though it has been controlled to a large it by correct pruning, present-day knowledge of lisease is not very detailed. Two recent papers in the *Annals of Applied Biology* (26, No. 3, August, 1939) describe investigations into the discharge and determination of spores (by R. G. Munson, pp. 440–457), and into the incidence and control of shoot infections (by R. W. Marsh, pp. 458–469). Perithecia are formed in the cankers, and the ascospores are forcibly ejected throughout the year, when atmospheric humidity is sufficiently high. Ascospore discharge is at a minimum in summer, however, but attains a maximum in January and February. Conidia are liberated during the wet periods in spring and autumn, and germination of both kinds of spore can take place between 2° C. and 30° C. The fungus therefore appears to be well equipped for parasitism, so far as its reproductive bodies are concerned.

Recent Volcanic Activity in Japan

ACCORDING to H. Tanakadate, volcanic activity in Japan during the period November 1935–December 1938 (*Jap. J. Astro. and Geophys.*, 16, Nos. 2–3, 93–121; 1939 Tokyo) may be divided into four groups: (1) Secondary phenomena having no direct connexion with deep-seated magma; (2) the Volcanian type of explosive eruption; (3) the Strombolian type of eruption; (4) the formation of a new volcano. Of the latter there were two: (*a*) Taketomi islet near Alaid Island (1934), which was of the homate type, and (*b*) Iōzima–Sintō, south of Kyūsyū (1934–36), which was of the tholoid type. What may be regarded as a typical volcano-tectonic earthquake occurred in part of the Kuttyaro Caldera, which is one of the largest in the world and noted for its sulphur production, on May 29, 1938, at 1.42 a.m. The top surfaces of both domes of Noboriondo and Maruyama fractured in the direction of the chain (N. 60° W.), the dormant fumerole on the northern side of the Oakota became active and the lake coast of the region rose about one metre in the north. It is believed that the earthquake was caused by movement of lava still in the molten state in the deep-seated root of the three domes. The most active volcano in Japan is that of Asama-yama, which is subject to frequent explosive eruptions of the Volcanian type. In the volcano observatory at Mine-no-Tyaya, 4 km. east of the crater, constant observations are carried out with seismographs, tiltmeters, earth current meters, magnetometers and other instruments. According to Minakami, the accumulation of ejectamenta on the crater rim reached 18 m. thickness from 1917–35.

The Goose Lake Siderite

PROF. F. C. LEONARD has a short account of this siderite in *Popular Astronomy* (47, 6; June–July, 1939). It was discovered on October 13, 1938, was removed a year later, and is now the property of the Smithsonian Institution and the United States National Museum. Its weight is 2,573 lb. (1,167 kgm.), and on etching the polished surface of a small fragment with dilute nitric acid, the characteristic Widmanstätten figures were seen, indicating that the specimen is a medium octahedrite. As all the original fusion crust is missing, it is thought that the meteorite is a very old fall. When the body was found about two miles west of the western shore of Goose Lake, it rested in the centre of a saucer-like depression about five feet in diameter and one foot deep. It is considered to be the fifth largest meteorite known to have fallen in the United States and the third largest on record for the three Pacific Coast States.

FUNCTION OF THE ELECTRICAL SUPPLY ENGINEER IN WARTIME

In the War of 1914–18 the supply engineer put to the service of the State his knowledge of the habits and business of those who lived and worked within his area of supply, not only as an individual but also backed by all the resources of his undertaking. Faced to-day with a similar crisis, Mr. J. W. Beauchamp, of the Central Electricity Board, recalls in an article published in *Electrical Industries* of November, what the supply engineer did during 1914–18. His main object was to assist the Ministry of Munitions and the Coal Control by pooling stocks, giving help in repairing damage or speeding up power supplies and dealing with the more difficult problem at that time of retaining skilled staff. All these were the subject of collective action.

The work was done with few formal meetings, but a large amount of personal effort and attention was given on the part of the staff. To-day the maintenance of supply and safety of the staff offers a much greater preoccupation. There is little time for discussion or inclination to go far from one's base, but the industry possesses a central development organization uniting all together, and able to pool ideas and unify action. The Commissioners and the Central Board in their respective spheres have formed a bond between the undertakings, and the Ministry of Supply itself includes the first chairman of the Central Electricity Board, a man whose work has left a great mark on the electrical industry of Great Britain.

Although reticence has become a virtue, few can fail to realize the great difference now governing the supply of lighting material and those which had to be met and remedied in the early years of the last war. Great factories created solely for defence can be supplemented by many but little smaller, which can be quickly turned from their peace-time activity to the production of the commodities required to keep a fighting force in action and make up its wastage. Much of the remarkable improvisation of 19 can be avoided, but if and when it becomes desi to enlist still more and perhaps smaller industrie it should be easy for authority again to utiliz local knowledge of the supply engineers and staffs. In most cases they have the entrée to v of every kind in their areas and the confiden the owners, and can often without delay su sources of supply and existing plant and labour to adapt to the mass production of simple iten components for use by more specialized man turers. The parcelling out of such work is not wit benefit as it stimulates local interest, holds tog business valuable in peace-time, reduces disloc of local labour and trade, bringing with it o tunities of training unskilled persons, and as often happened in the past, introduces into works methods of production and degrees of acc which prove of value when normal labou resumed.

In 1914 we had no experience of a contest bet highly mechanized States. A thousand devic attack and defence had been as yet unborn. A all, there is the air menace which makes fro a plane rather than a line. In the electrical indu the interval covers many changes, notably collective control, administration by the Con sioners, operation by the Board, development research by associations, and a close co-oper amongst those who produce and instal elec appliances.

The outlook of the public towards electrici now quite different. To-day all branches o industry in combination provide the greatest p utility in the modern State, and the one in v the operators and their staffs have the most c and frequent contact with the millions who electricity for personal service or as a compone their trade or industry.

TRIBAL ORIGINS AND CULTURE AMONG THE FOX INDIANS

An ethnographical account of the Fox Indians has recently been issued by the Smithsonian Institution. It has been edited by Margaret Welpley Fisher, and is based upon material which has an exceptional claim to authority. The author, William Jones, was born on the Sauk and Fox Reservation in Oklahoma in 1871. His mother was English, but his father was the son of a white man and an Indian mother. Up to the age of nine years, Jones was reared by his Indian grandmother, living the life of an Indian boy. On her death and after a period as a cowboy, he entered the Hampton Institute, passed to Andover and Harvard, taking the degree of M.A. at the latter in 1900 and Ph.D. in 1904. His intention had been to study medicine ; but under the infl of the late Prof. Putnam he turned to anthropo spending his vacations in field work among A quian tribes and making a comparative stud Algonquian religions. This field, however, aff little hope of a career in research ; and in 190 Field Museum offered him the choice of three ex tions, of which he elected for an expedition t Philippine Islands. In the spring of 1909 he murdered by the Ilongots.

Before his departure for the Philippines, had already published some of the material he collected in the field, while other studies were i posthumously. The greater part of his papers, ever, and that containing what now appears to been the more valuable results of his inquiries, missing. Its whereabouts was unknown until, o

---

[*] Ethnography of the Fox Indians. By William Jones, edited by Margaret Welpley Fisher. (Bureau of American Ethnology, Bull 125) Pp. iv+156. (Washington, D C.. Smithsonian Institution, 1939)

ath of his father a few years ago, it was disclosed the family lawyer, who forwarded the papers to Smithsonian Institution, that the father of 'lliam Jones had kept the existence of these papers ecret, as he had felt that much of the information ulged to his son had been due to his own friend- p with the Foxes and, therefore, had been un- 'ling that it should be published during his lifetime. A sealed packet said to have contained an account "ancient mysteries" never previously revealed to vhite man, to which reference is made in "William nes" by Henry Rideout, has not yet been identified th certainty, although its existence has been con- ned by inquiry. Certain passages in the present ount are indicated tentatively as possibly em- dying this material.

he Fox Indians are of particular interest as turally intermediate between the tribes of the stern woodlands and those of the Great Plains. eir language is the most archaic of the Algonquian gues; and with the Mexican Kickapoo, their dred, they rank among the most conservative of Indians. Hence until a few years ago, they were garded as representing in their culture an archaic x pattern, and considered types of the "Central gonquian". Examination of their history has akened this view and indicates that there is no ans of knowing how far it represents the truth. culturation has been carried to such lengths that would be remarkable if many specifically Fox its remained.

Knowledge of Fox history begins in 1640, when Huron map was drawn up for the Jesuits. They d then been driven westward by hostile tribes, th whom they continued in conflict until the ival of French traders in 1665. From that time ward, the French waged a war of extermination ainst the Foxes, whose country on the Fox-Wisconsin waterway was a preferred route to the Mississippi and a strategic point for trade. Failure to secure their adhesion to a French scheme of pacification of Indian tribes with Detroit as the concentration point embittered a struggle which culminated in the virtual extinction of the Foxes in 1728, when they were intercepted while trying to escape into Iroquois country. After a conflict lasting twenty-three days, only some fifty or sixty got away alive, or as it was expressed afterwards by a member of the tribe, in speaking of the wars with the French, "once there were only 3 lodges of the Fox Indians left".

However, in the winter following the massacre, the membership of the Fox tribe had risen again to 250. This and previous regenerations of the tribe had been effected in two ways. Prisoners were captured in war for the purpose of adoption into the tribe—the Pawnees, in particular, had been the victims of such attacks; and through the good offices of western allied tribes, Foxes who were held prisoners by hostile tribes were released and allowed to return to augment the tribe. These two elements, though politically all members of the Fox tribe, culturally had wide and various roots.

In the numerous vicissitudes and migrations of the tribe, in which they suffered severely from cholera and smallpox, settlements were formed in Kansas, Iowa and Oklahoma. The records show a close and prolonged association with the Sauk, and the incorporation of elements from Potawatomi and Winnebago. A tribe thus many times depleted and restocked, although strongly resistant to white culture, is scarcely likely to have escaped the cultural influence of the many and intimate relations with other tribes. Hence at the time information was collected by William Jones, any assumption of the archaic and original pattern of Fox culture had become hazardous.

GRASSLAND AND FORAGE CROPS IN THE UNITED STATES

NFORMATION with regard to forage crops, range management and the botanical aspects of soil nservation in the United States is either not ailable in published form or is scattered among a ge number of reports. The Imperial Bureau of Past- s and Forage Crops at Aberystwyth has accordingly pared a bulletin, compiled by R. O. Whyte, entitled esearch on Grassland, Forage Crops and the Conser- tion of Vegetation in the United States of America" erbage Publication Series, Bulletin 26. 5s.).

The bulletin deals first with the work of the Division Forage Crops and Diseases, each of the five crop oups being studied from the point of view of culture d production, breeding and improvement, and eases. An important recent development has n the organization of the U.S. Regional Research boratory, State College, Pennsylvania, which uld become one of the leading world centres for study of problems connected with humid tem- ate pastures. The range investigations of the rest Service are then described. These are intended to supply basic information for the intelligent utilization of the land, the field work being organized into six regional forests and range experiment stations, covering the western United States. The research of the Soil Conservation Service deals with many aspects other than the use of grassland and forage crops as a protective cover for soil, and some account is given of the terms of reference of the eight branches of the Division of Research in the S.C.S., information not already published in Bulletin 25 being included.

Brief reference is made to the studies in progress under the auspices of the U.S. Golf Association, and details given of the ecological research at the Carnegie Institution of Washington regarding factor and function in adaptation, climax, succession and conservation.

The remainder of the bulletin contains relevant extracts from the most recent annual reports from practically all the agricultural experiment stations in the United States.

TRANSITION FROM CHARCOAL TO COKE IN IRON SMELTING IN BRITAIN

RATHER more than a year ago, the secretaries of the Royal Society of Arts discovered several bundles of old letters written to the Society between 1750 and 1800. The find is rich in information relating to the then manifold activities of the Society and to the inventors of those days. The careful study of the letters by appropriate experts may be expected to throw much light on an all too little known aspect of history, that of technical progress.

Unfortunately, the disturbed state of the world made it advisable to place the letters in safe keeping before the plans for their investigation could materialize. A beginning, however, had been made, and one letter by J. Wilkinson, probably the same Wilkinson who produced cannon during the Napoleonic wars, formed the *raison d'être* of a paper by Mr. H. Gwynn Jones on the charcoal iron industry, delivered before the Royal Society of Arts on November 15

Iron was at first smelted with charcoal by the direct process, wherein furnace and forge were under one roof. As the amount of charcoal within economic range became exhausted, the indirect method came into vogue in which pig iron was made in one locality and forged in another. The metal was run into a bed of sand furrowed-herring-bone fashion, and when cool broken into the 'sow' or central furrow and the 'pigs' or offshoots.

The evidence afforded by the location of the early iron works, which demanded a supply of wood for charcoal, of iron ore, water transport and swift-flowing streams for power, gives an indication th the scarcity of charcoal was wide in its influence the iron industry. The search for a substitute beg before the eighteenth century; the first patent coke was taken out in 1627, and apparently t Darbys of Coalbrookdale had established oc smelting of iron on a commercial scale by 1709, but was thirty years or more later before a method of usi coke in all the processes of smelting was discovere

The long letter to the Society of Arts from Wilk son written in 1761 makes it clear that at that d iron was produced mainly with charcoal. He sugge that the Society should consider how to make co pig iron as good as that made with charcoal, ne how to make tough bar iron from the coke pigs, a finally how to convert these into steel equal in goo ness to that made from Swedish bar iron. He write "this Kingdom has materials enough to make all t iron that is consumed provided the coke scheme c be established in the making of pig iron equal goodness to those made with charcoal".

His remarks, besides showing that the ir industry was tied to charcoal in 1761, foreshad the changes which were to take place in the Brit iron industry when iron and coal were finally wedd causing it to lead the world for at least a centu

As a result, the industry abandoned its scatte homes and became established in localities wh coal and iron were found side by side; a wood district with rapid streams was no longer necessa

TORSIONAL EFFECTS OF TORSIONAL OVERSTRAIN IN MILD STEEL

A PAPER by Prof. H. W. Swift on the torsional effects of torsional overstrain in mild steel, which had been prepared for presentation at the cancelled Cardiff Autumn Meeting of the Iron and Steel Institute, has been abridged and is published in *Engineering* of October 20. The usefulness of a material for manipulative processes in which severe plastic deformation is involved, depends primarily on the range of elastic flow to which it can safely be subjected. This depends in turn on, first, the stress-strain characteristics for the material within the elastic range; secondly, the stress-strain characteristics for the material within the plastic range; and thirdly the cohesive properties of the material which resist rupture.

The conditions of elastic breakdown have been the subject of much study and discussion. Some theories still have their champions, but most engineers regard maximum stress as the criterion of breakdown for brittle materials and shear strain energy (or shear-stress on the octahedral planes to which this is implicitly related) for ductile materials. In a ductile material it is generally thought that rupture occurs by shear. In a tensile stress the familiar cup and cone fracture indicates sliding at the instant rupture, and in torsion the surface of rupture is transverse plane of maximum shear stress. But has been proved that the process of rupture at t neck of a ductile bar in tension always commen inside the material across what is substantially plane of maximum tensile stress. Shear sliding the cup and cone basis sometimes occurs to measurable extent after fracture has been initiat

Simple tension and simple shear are the t simplest methods of making exploratory tests. addition, measurements of hardness are taken on t surface of tension of torsion bars at various sta of overstrain, and plotted in diagrams. Tables shown of the principal test data relating to t tensile properties after torsional overstrain. It w found that after fracture had commenced (internall which was proved by the sudden drop of the be of the testing machine, a certain amount of draw continued in the unbroken outer angular ring, a the diameter at the neck after complete separati was measurably less than that when the fracture co menced. It was found that neither strain energy hardness was a controlling factor in regard to ruptu

CIENCE NEWS A CENTURY AGO

nch's Explorations in Mesopotamia

AT a meeting of the Geographical Society on ovember 25, thanks to the president of the India oard, a communication was read from Lieutenant enry Blosse Lynch (1807–73) of the Indian Navy lating to his survey of the River Tigris between esiphon and Mósul. "Chains of triangles," said nch, "covered Nineveh to Baghdád, Baghdád to bylon, Babylon to Ctesiphon, Ctesiphon to Baghd, and the mountains of Hamrín in two points, mely, where the Tigris bursts through them in the ., and Wiyálah to the north-eastward; most of the incipal points within the range of these are fixed her by an extension of the trigonometric chains, or latitudes and true bearings checked by longitudes; e great canals also have been touched by our work fficiently to show their direction and position. As work, the field, instead of being diminished, pears to extend; and I have been obliged to leave th regret the tracing of the splendid canals and ers, and the filling in of the villages and ruins, for re favourable times. . . ."

niversary Meeting of the Royal Society

IN his address at the anniversary meeting of the yal Society on November 30, 1839, the president, e Marquis of Northampton, said that "the past ar has indeed been to that portion of the Royal ciety which takes an active part in its affairs, one more than usual labour and exertion—of labour d exertion, destined, as I hope, to produce rich d ample fruit. The great and marking peculiarity ich has attended it, has been the sailing of the tarctic Expedition. . . . The Expedition has w sailed, amply provided with the best scientific truments and furnished with ample scientific tructions. . . . I have stated, Gentlemen, that ur Council had recourse to the Scientific Committees assistance in drawing up instructions for the pedition in different branches of knowledge; ose committees, who were named only two years o, were at first apparently more a matter of form an substance; they have now been capable of ing excellent service".

The Royal Medals for 1839 were awarded to Dr. rtin Barry (1802–55) for his researches in embryoy and to Sir James Ivory (1765–1842) for his estigations on astronomical refraction, while the pley Medal was awarded to Robert Brown (1773–58) for his "Discoveries during a Series of Years the Subject of Vegetable Impregnation". Humdt. denominated Brown "botanicorum facili prins". The son of a Scottish clergyman, Brown, after ending the Universities of Aberdeen and Edinburgh, s made an army surgeon. At the age of twentyen he became known to Sir Joseph Banks, through om he was appointed naturalist to the expedition t to Australia in 1801 under the command of ptain Matthew Flinders. When Brown returned England four years later he brought back a lection of 4,000 plants. Soon after his return he s made librarian to Banks and in 1823 became sessed of both his library and herbarium. The lection of plants he offered to the British Museum, l in 1827 he became keeper of the botanical department in the Museum, a post he held until his death. was admitted F.R.S. in 1811, in 1833 was elected a eign associate of the Paris Academy of Sciences, and 1849 was chosen president of the Linnean Society.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

TEMPORARY ASSISTANT LIBRARIAN—The Registrar, University College, Southampton (December 6).

NUFFIELD PROFESSOR OF ORTHOPAEDIC SURGERY—The Registrar, University Registry, Oxford (December 16).

SCIENCE AND THE NEW EUROPE

OR some weeks past, much paper and ink have been expended in discussing the war aims of Allies. Although the British and French miers and others have declared repeatedly l on various occasions that the purpose of Allies is to put an end to the constant gressions of Germany, in the interests of peace ong the European peoples, there are those who l that, as thus stated, Allied aims are not ficiently defined. Hence there is frequent ference of opinion as to whether, in arriving at terms of a peace, it will be possible to dis-minate between the Nazi Government and the rman people. In this connexion, Mr. Chamber-n's restatement of the aims of Great Britain and Allies in his broadcast of November 26 as "the eat of that aggressive, bullying mentality which ks continually to dominate other peoples by ce, which finds a brutal satisfaction in the secution and torture of inoffensive citizens, and the name of the interests of the State justifies repudiation of its own pledged word whenever inds it convenient" should allay all doubt.

So clear and comprehensive a summing up of forces to which the Allies are opposed, and which they are determined to put an end, be y Nazi or characteristic of the German people large, leaves no room for ambiguity or extenua-n. In the pages of NATURE, however, and with advancement and interests of scientific truth re especially in view, it is permissible to phrase objective in even more precise terms without ential modification of substance, yet at the ne time clarifying the issue. To every man of ence it should be an article of faith that any w of the State and of the duty of the citizen that State which require from the research worker, the man of science, or the teacher the distortion of scientific evidence, the suppression of any scientific truth, and the elimination of all freedom of thought which runs counter to the prevailing political theory, are abominations which must be destroyed, root and branch. Continental commentators on the war aims of the Allies, who are close observers of the German scene both at the moment and in historical perspective, have pointed out that while the German philosophy and mentality function in terms of 'power', Great Britain and France are thinking in terms of 'liberty'. Although the German people have been moulded by the Nazis to the ends of 'power politics' more drastically than ever before, it is no doctrine of to-day or yesterday. It goes far back in the history of the German people. How this should bear upon the attitude of those who have at heart the true interests of scientific thought and the advancement of scientific knowledge it is perhaps unnecessary to inquire. The moral is obvious.

Contributions to the recent discussion of war aims have brought to light many interesting differences of opinion and diversity of view. The 'New Europe' of which Mr. Chamberlain spoke is not one in which the map has been redrawn according to the ideas of the victors, but a Europe in which "the nations which inhabit it will approach their difficulties with good will and tolerance". Mr. Chamberlain went on to define the conditions of lasting peace as involving in the first place a full and constant flow of trade between the nations concerned, with an increased interchange of goods and services by which the standard of living could be improved; secondly, that each country would have the free and unfettered right to choose its own form of internal government, so long as that government did not pursue an external policy injurious to its neighbours; and thirdly, that in Europe armaments should be dropped as a useless expense, except in so far as needed for the preservation of internal law and order. As a corollary, he contemplated as necessary some machinery capable of conducting and guiding the New Europe in the right direction. Not unnaturally, Mr. Chamberlain did not feel called upon, nor indeed did he think it possible at this stage, to specify the kind of machinery which should be established for this purpose.

Although Mr. Chamberlain's foreshadowing of the possible course of post-War events must be still fresh in the minds of all, it is perhaps not superfluous that it should be recapitulated here. For the man of science this forecast bears a special significance. To him as a citizen it carries—as indeed it does to all—a message of promise and hope at a time when the very foundations of honour and decency of life in a civilized community are under grave threat. But for the man of science in the exercise of his special function as one whose work directly or indirectly comes ultimately to bear on the better organization of civilized life and its amenities, Mr. Chamberlain's words convey a deeper implication, and in a twofold sense. Of all the forces which in the interval between the last and the present War have made for international co-operation and mutual understanding between peoples—an essential condition of lasting peace—few have been more effectual than science. This has been due not merely to the effect produced by co-operation in research and the pooling of results, but it has arisen also out of the manner in which science has devoted itself to a world-wide, objective and impartial study of certain facts, and the application of the results of such study in efforts to raise the general standard among peoples in such matters as nutrition, personal and social hygiene, conditions of labour, production and exchange, and a hundred and one other problems which vitally affect the well-being of communities and the happiness of their members. As must be inevitable after a great war, the need for these services will be intensified at the close of hostilities, and it may be assumed that to cope adequately with the conditions which will then prevail will demand a gigantic effort in which international co-operation alone will be equal to the strain.

More immediately, however, in Mr. Chamberlain's New Europe it will be incumbent u
science, and more especially the biological
humanistic sciences, to place their knowled
their methods of inquiry, and the results of th
research at the disposal of the friendly conferen
of which Mr. Chamberlain spoke, when they m
to adjust boundaries, to discuss the econo
problems of productions, currency and exchan
and to consider those other problems with wh
they will have to deal to ensure the lasting pe
for which we hope. It is equally essential that t
body of specialized scientific knowledge should
at the service of that body, or machinery, wh
is to guide the development of the New Euro
whatever may be its form and whatever
authority which it may carry to enable its ruli
to prevail. Only on this condition and by
utilization of such specialized knowledge to
full will it be possible to avoid the mistakes o
second 'Versailles'.

Political philosophies have alternated betw
'force' and 'consent' in their analyses of the for
which contribute to the origin and growth
societies. Possibly a happy compromise betw
the two has in most instances brought about so
state of equilibrium, a generally acceptable w
of living. If force—the big policeman—is necess
to coerce the criminal, the perverse, and
members of an intractable minority, it is a fo
wielded in the interests of, and with the consent
the majority. The preponderance of that major
and the unanimity of its consent to the exercise
force both as an instrument of, and as embodi
in, law and order, must depend upon the recogniti
of a number of common aims among the memb
of the community and the extent to which e
individual is prepared to curb his idiosyncrasi
should there be any to which the curb should
applied in the interests of other members. T
same applies, or perhaps it would be more corr
to say it is an ideal which should apply, in t
relations between States and peoples. For it
the teaching of anthropology that each peop
each national group, has its idiosyncrasies, li
an individual—idiosyncrasies which are the produ
of a long history of cultural development
Europe going back to the Dark Ages, and inde
far beyond. Further, we learn from such stud
that such a cultural heritage in the long run nev
submits to force, but itself vanquishes force in t
end. Such modification as the cultural herita
may undergo in the course of development—a
it is unquestionable that such transformations

ethnic group have taken place on many asions—this is brought about by cultural con-t and cultural exchange no less than by the rse of an internal cultural evolution (to use the m evolution in its more popular sense). Is this solution of the German problem, the problem ich to some seems insoluble without a change the heart of that people as a whole, but of which present there seems little prospect ?

The major problem of the post-War world will the reconciliation of the cultural heritage, national spirit of each ethnic group, with the mmon aim of a New Europe. If the guiding body or machinery of which Mr. Chamberlain spoke is to avoid the error of an earlier settlement, study of the problem which respects cultural and ethnic history must be invoked toward a solution. Then it may be possible to ensure international co-operation in a maximum of joint effort towards those common aims to which science, among other social forces, will point the way. The greater the common field in which co-operation can be brought about, the less the need is likely to arise of coercing the recalcitrant and the aggressor by the threat of the big policeman—a major European war.

AMERICAN MINERAL DEFICIENCIES

ategic Mineral Supplies
G. A. Roush. Pp. xvii+485. (New York and ndon : McGraw-Hill Book Co., Inc., 1939.) 33s.

S a by-product of recent discussions about resources in essential raw materials, the rd 'strategic' has acquired a specially limited nificance in the United States. It refers to those terials which are not obtainable from within national boundary in sufficient quantities to et current industrial needs and therefore, in es of emergency, military necessities as well. e peace-time and war-time requirements of modern State now differ quantitatively rather n qualitatively, and so the list of contraband terials has become extended very widely by all tes.

The political atmosphere of the last six years undoubtedly stimulated a specially intense mination of this subject, and study of the blem of self-sufficiency is naturally not an un-asing theme to Americans ; for no other political it has so few gaps in its defences to repair ; has h small difficulties in securing supplementary plies from outside ; or is so well developed in industrial configuration to absorb and turn to rketable or military account these imported ategic raw materials. For an industrialized ntry deficiencies in a few minerals are more ious than any shortcomings in vegetable pro-cts, because the former are distributed over the be in workable deposits without regard to mate or political boundaries ; they cannot be de artificially ; they cannot be transplanted ; d only to a very limited extent, and then with ne loss of efficiency, can the abundance of e material be made to make up for shortage another.

In the United States ten minerals are listed by the War Department as 'strategic' ; these are not, and are not likely, to be found there in quantity or quality to meet the demands which would certainly occur during war with any great Power. There are others officially classified as 'critical' which can probably be assembled in sufficient quantities by conservation and distribution control ; they are not, as Mr. Roush says, likely "to give rise to many headaches". Then there is the much longer pleasing list of 'essential' minerals which occur in obvious abundance in the States, some with a surplus for export.

With the exception of a short final few pages on the deficiencies of the other six great Powers, this volume is limited to a study of the American ten strategic minerals—manganese ore, nickel, chromium, tungsten, tin, aluminium, antimony, mercury, platinum and mica—in addition to iodine and nitrogen, which are essential but can easily be obtained when necessary. This list also shows roughly the order of importance of these minerals for war purposes, and involuntary emphasis on the meaning of the word 'strategic' is shown by giving full consideration, in the first place, to manganese ore, the substance which gave the American steel-makers serious cause for anxiety during the War of 1914–18.

Very full data, graphically illustrated, are given for each of these minerals—the amounts required, their uses and ways of utilization, their occurrences, the partial substitutes obtainable for some of them, their outputs, prices, import tariffs and forms of control, followed in each instance by an appreciation, as the tactician would say, of the resultant domestic situation. As the editor, since 1914, of the annual publication well known as the *Mineral*

Industry, Mr. Roush has acquired a position of special authority, which his own Government has turned to further account by his appointment to the Staff Specialist Reserve of the United States Army.

The information packed by the author into 485 pages cannot be further condensed. That is one of the disconcerting features of all discussions on mineral raw materials; each mineral has its own special importance; and in an emergency, the want of any one of them may render ineffective the value of all the others. The politician's satisfaction in "looking at the question as a whole" is here of no practical value. "The problem," as Mr. Roush says in his general summary, "is not only a different one for each individual metal, but for each separate use of the metal." He takes the metal platinum as an illustration and points out that, whilst general substitutes are quite unobtainable, some cheaper substitutes can to a limited extent be used to reduce the demand for the expensive metal: fused silica can partly replace platinum in the chemical laboratory; a nickel-iron alloy can be used as a lead-in wire in electric-light globes; vanadium oxide is used instead as a catalyst in sulphuric acid manufacture. But no material has ever been found which can take the place of platinum in all its wide variety of uses. In other words, an industrialized nation *must* have platinum, for one thing; and each country has its own special list of other strategic deficiencies.

Among the alloys, however, substitution is possible to a greater extent; but again either at a higher cost or with some loss of efficiency. The institution of new alloys is now nearly a monthly occurrence, each in turn putting a predecessor out of the field under conditions of keen competition, commercial or military. So, within the territory of a highly industrialized great Power at war, the progress of scientific and technological research is more significant now than it ever was before; even from the purely military point of view it is short-sighted of any nation to decrease, for ideological reasons, its list of 'strategic' men of science.

We must, however, resist in this short review the temptation to follow up this line of thought, and refer now very briefly to some of the more direct lessons which Mr. Roush discovers in his study of the few American mineral shortcomings. He realizes that in general it is useless to encourage an increase of a peace-time production when, as in the instance of nickel and tin, there are practically no domestic natural resources to develop; that artificial efforts of the sort may add another danger if the small natural reserves are likely thereby to become exhausted. He points out the advisability, however, of a very limited peace-time activity in producing those minerals which cou when necessary, be produced in quantities s stantially sufficient to reduce the dangers o shortage during a sudden emergency. He wo encourage the use, in recoverable forms, of i ported metals as one way of building up stock for he realizes the financial burden of artificia creating stocks sufficient to cover one or two ye war supply. But this plan nevertheless seems be the only safeguard which he can recomme and it is apparently gaining favour in the Uni States since it was proposed by the Leith Co mittee some fifteen years ago to meet the dan of a manganese ore famine. Other than th direct measures, Mr. Roush points out the necess of instituting a systematic and continuous accu lation of information regarding foreign sources nearby supply, some of which might be accessi in time of war.

This leads Mr. Roush to point out the seri nature of the dangers to his own country wh would follow from a war with Great Brita but he nevertheless derives some comfort fr the well-founded assumption that any such disas is very unlikely. Great Britain too might v take note of the same danger, and for a simi reason derive the same degree of comfort; whilst the British Empire as a whole has a sho list of strategic minerals than any single politi unit, the sources of supply are widely separa from the chief industrial area, and are now un the control of free and politically independ States which still maintain tariffs for their o immediate needs.

One lesson, often mentioned by others befo peeps out occasionally in this work—the impo ance, both economic and military, of smelting a refining at home, whatever be the source of t ore. As an example of the way in which the Brit Government learned some wisdom from the co mistakes of the War of 1914–18, Mr. Roush quo the subsequent action of British Guiana in gra ing a concession to an American company to m bauxite, on the condition that it should be smelt within British territory, one result being the bui ing in the Province of Quebec of the largest sin aluminium plant in the world, in spite of the f that its location is remote from the chief mark for the refined metal.

Although this volume is devoted admittedly a entirely to the consideration of direct Americ interests, the mass of trustworthy informati which it contains indicates lessons of vital inter to those British public leaders who seem to thi that as Providence has endowed the British Emp with unequalled natural resources, Providence w also arrange for their easy assembly and utilizati in times of need. T. H. HOLLAND.

PROTEIN CHEMISTRY

Chemistry of the Amino Acids and Proteins
ed by Prof. Carl L. A. Schmidt. Pp. xxiv+
. (Springfield, Ill., and Baltimore, Md.:
·les C. Thomas, 1938.) 7.50 dollars.

OM the time of Osborne's pioneer researches on the plant proteins, American chemists biologists have shown the liveliest interest in field of investigation, and it can safely be that in no country to-day is a greater pro-ion of the total researches concerned with ein problems. Not only do American names e prominently in the history of protein dis-ries, but also for convenient accounts of the : of many European investigators, such as nsen and Svedberg, we are indebted to rican enterprise in arranging lecture visits to American publishers for issuing the lectures onograph form.

e present volume represents a courageous t by sixteen contributors, who with the ption of Prof. Gorter and his assistants Drs. kant and van der Dusen are all American, to , world-wide need for a reference book on the o-acids and proteins. It is in no sense a book he beginner—but fortunately there are many . It should be acquired by most libraries and esearch workers in the protein field because it cts in the scope of one volume so much that cattered and inaccessible, and because it odies a wider review of the literature than hitherto available.

one important respect it fails, however. reas the individual contributions are excellent, ther, they make an ill-assorted collection with ble omissions which fails to convey a sense of perspective of the protein field as a whole. example, Dr. Michael Heidelberger contributes ost informative chapter on proteins in im-ity, but there is no adequate supporting on in the book dealing with the compounds roteins with carbohydrates and lipoids so rtant in immunity phenomena. The role of eins in nutrition receives 20 pages; their roles spiration, and in preserving the water balance e organism, on the other hand, are not dis-d. The latest views on protein structure iated with the names of Astbury, Wrinch, mann and Niemann all receive ample atten-, but the chemistry of the enzymes and nucleo-ins, two fields which have developed out of ognition in recent years, is omitted altogether.

The section dealing with the preparation of the proteins is quite inadequate. A scant 8 pages is devoted to this, which stand in marked contrast to a comprehensive description extending to 47 pages on the isolation and preparation of the amino-acids. Casein receives a paragraph in which no mention is made of Van Slyke and Baker. There are no references at all to Palmer's crystalline lactoglobulin or to Kekwick's diffusible protein in milk, or to the preparation of insulin or thyroglobulin. While the physical properties of myosin are adequately described, there is no mention of its preparation or of the other proteins in muscle.

The book is strongest in its treatment of the amino-acids and the physical chemistry of the proteins. Dr. John Edsall contributes an outstanding section extending to 80 pages on dipolar-ionic structure and the solubility relationships of the amino-acids and proteins. The section on the molecular weights of the proteins is valuable only in relation to osmotic methods of measurement. In the section on diffusion the obsolete fluorescence method of studying diffusion is described and illustrated, whereas the later technique and results of Lamm and Polson are not mentioned. The description and illustration of the Svedberg equilibrium centrifuge refers to the original model built in 1924, which was radically altered a few years later. The sedimentation velocity centrifuge is represented as improving and supplanting the equilibrium centrifuge, whereas in fact the two measure different constants and are complementary. It is a pity that in an otherwise exhaustive section on the electrochemistry of the amino-acids and proteins the new electrophoresis technique described by Tiselius early in 1937 has not been included.

The reviewer is fully conscious of the immense difficulties which face anyone courageous enough to attempt the production of a comprehensive text-book on such a rapidly developing and many-sided subject as protein chemistry. The example before us must be judged in the light of these difficulties. Whereas the book is defective in many respects and may not be compared with numerous classical works of reference in other subjects, it must be acknowledged and welcomed among protein chemists as the best available to meet their needs at the present time.

A. S. McF.

WOOD AS A RAW MATERIAL

Das Holz als Rohstoff
Seine Entstehung, stoffliche Beschaffenheit und chemische Verwertung. Von Dr. Reinhard Trendelenburg. Pp. 435. (München und Berlin : J. F. Lehmanns Verlag, 1939.) 14.50 gold marks.

FROM the earliest days of civilization, wood has ranked as an important constructional material on account of the ease with which it is obtained and worked with the simplest tools, and because it combines in a striking degree a relatively high strength with moderately low density. The wide, and only partially controllable, variations in properties which it shares with other natural products have tended in recent years to place timber at a disadvantage in competition with a number of highly standardized constructional materials now on the market. Any decline in consumption due to this circumstance has, however, been more than offset by the development of new methods of manufacture which promise to overcome the difficulties caused by variation, and by the increasing use of wood in the preparation of paper pulp, cellulose, charcoal, and other substances. The more intensive utilization in these directions calls for a fuller understanding of the origin, composition and structure of wood, and Dr. Trendelenburg's book supplies an excellent introduction to the present state of knowledge in these fields.

Most text-books of wood anatomy include detailed accounts of the microscopic structure and the preparation and examination of material, and they are designed to meet the requirements of readers primarily concerned with the identification of specimens of timber or with the grading and use of timber in situations demanding good appearance or high strength. Dr. Trendelenburg's book is largely supplementary to these ; general structure and laboratory methods are dismissed in a few pages which are perhaps included merely as a matter of form, since they are probably beyond the grasp of readers not already familiar with their import, and the major portion of the book discusses structure and physical properties more particularly in relation to the use of timber in the production of secondary materials.

Two brief introductory sections describe the composition and distribution of the German forests, and give a general account of the production of timber for the benefit of readers who are not foresters ; the final section has brief notes on the production of pulp, cellulose, sugar, cha wood gas, wood wool, and fibre board.

The third section has descriptions of the ch teristic elements and tissues, and discusses causes and significance of variations in size o elements and proportions of the tissues. Cu methods of dealing statistically with variatio recommended by the International Associati Wood Anatomists, are given. Reference is to the principal chemical constituents an recent work on the fine structure of the cell The keynote of the fourth section, which with the gross anatomy of the stem, is given quotation from Nordlinger to the effect that the cell is to the physiologist, so is the gr ring to the scientific forester". Developme the growth ring throughout the year is traced the various factors influencing ring width examined. Nearly half the section is conce with sapwood and heartwood, and the accou the best yet published.

The fifth and sixth sections, together compr nearly half the book, are devoted to problem moisture content and specific gravity. Both perties have an important bearing on the yiel the products listed in the closing section of the b Variations in moisture content in different of the living tree are described in relation to se of the year, locality, and species. The conce of fibre saturation point as the moisture con at which the cell walls are saturated while no water is present in the cell spaces is mere convenient assumption for practical purposes, reference to the recent work on the subjec Barkas would have made this interesting se more nearly complete. It may be mentioned 'collapse' is not confined to dense timbers, as m be inferred from the text ; several light, soft timbers are very prone to collapse in drying, with some of these reconditioning appears t impracticable. The treatment of specific gra is equally full and interesting.

In addition to descriptions of extensive ori work, Dr. Trendelenburg refers to more tha hundred papers, more than half of which appeared since 1930 ; some four hundred and are in German, and the references to a volume of early German literature are particul valuable to English readers.

The book is well indexed, having catalogue literature, authors, species, and subjects occup 45 pages.

S. H. CLARK

NEW TECHNIQUE IN PHYSICAL CHEMISTRY

BY DR. H. W. MELVILLE, DEPARTMENT OF PHYSICAL CHEMISTRY, CAMBRIDGE

ODERN physical chemistry has now such wide ramifications that it is not easy to ımarize compactly its recent endeavours. A ınber of the newer aspects of the subject were ussed from the point of view of the invention new technique at a meeting of Section B emistry) of the British Association held at ndee on September 1. The development of such hnique is a vital part of physical chemistry, and ny recent discoveries are a direct consequence these advances.

here are in chemistry innumerable problems, n concerning well-known and simple systems, ich have formed bones of contention for many rs. No amount of theoretical treatment will vide a solution. What is needed is a simple and ıclusive experiment to settle the question once l for all. The region for inventiveness is thus wide scope. The problems which have arisen mainly those having to do with the mechanism hemical reactions, and there are essentially two sons for this state of affairs. What may be ed 'classical chemistry' has established the ds of molecule which enter into reaction and what sorts of products emerge therefrom. But ould only surmise what happened in the interliate stage of events. Certainly it was known t some kind of chemically reactive molecules k part in the reaction. The trouble is, however, t the fraction of molecules involved is generally minute that no method of analytical chemistry ensitive enough to detect their presence, apart gether from determining their nature. Thus rder to discover how reaction occurs, essentially erent methods have to be developed to perform difficult task. These problems only arise, of rse, in relatively slow reactions; very fast ctions are still outside the scope of experintal inquiry, although progress is being made selected cases. Another problem often arises e the general question of mechanism is settled. en a polyatomic molecule containing a number similarly disposed atoms undergoes reaction, it lso necessary to know what particular atom is ually involved. This question is now settled h great success by isotopic methods when nples of relatively pure isotopes are available. he first part of the general problem is by no ans solved at present. In dealing with such ute quantities of various molecules, any hod used to measure their concentration must , of course, alter that concentration significantly, otherwise the mechanism may be so much disturbed that the results obtained are invalid. One of the best examples of the development along these lines is the use of *para*-hydrogen for the measurement of hydrogen atom concentrations, in those processes where atomic hydrogen is believed to play a part, as for example in the heterogeneous and homogeneous reactions of hydrides. The method has the great merit that since conversion is brought about by exchange of atoms thus:

$$\mathrm{H} + p\text{-}\mathrm{H}_2 = o\text{-}\mathrm{H}_2 + \mathrm{H},$$

the hydrogen atom concentration is not disturbed. It may be mentioned that atomic concentrations as low as 10^{-7} mm. of mercury may be so measured.

Naturally the method is a comparative one in that the reaction being investigated is really compared with that of conversion. Suitable conditions can, however, be chosen to cover a very wide range of concentrations. One example must suffice to indicate the kind of problems that can be solved. Ammonia is decomposed by light of wave-length 2000 A. to nitrogen and hydrogen, only one molecule decomposing out of four absorbing radiation. Admixture of *para*-hydrogen shows that the primary dissociation is to H and NH_2, but only about one half of the molecules decompose in this way. This alone does not explain the low quantum yield. Another technique shows that part of the inefficiency of the gross process is due to some recombination of H and NH_2 to form NH_3, for the decomposition is inhibited by atomic hydrogen produced at a controlled rate and checked by the *para*-conversion.

Similar methods with many ingenious modifications may be applied to all homogeneous hydride reactions in which atomic hydrogen is presumed to play a part. Although the same technique may be employed in heterogeneous reactions, the addition of *para*-hydrogen sometimes alters the character of the adsorbed layer on the catalyst, and therefore makes the results more difficult to interpret.

In reactions involving halogens, atomic halogen frequently is the active species concerned, whether the reaction be induced thermally or photochemically. Fortunately, in view of the comparatively low energy of dissociation, the equilibrium constants for dissociation are known accurately, and thus stationary atom concentrations are easy to compute. If, however, there is a disturbance of the stationary concentration by any competing reaction, then both rate of production and rate of removal of atoms must be known. It is the latter quantity that is the more difficult to measure. Two methods have been developed. One consists in actually measuring the decrease in the number of halogen molecules on illuminating the system, by an optical differential technique. The other consists in a proper examination of the expansion halogen vapour undergoes on illumination, that is, the Budde effect.

The behaviour of other reactive chemical entities such as OH, NH_2, CH_3, C_2H_5, and so on, have been examined with similar but less refined methods, and there is here much work to be done before a complete correlation of all the data can be effected. For example, the life-time of these radicals can be determined by producing them photochemically and allowing their concentration to fall in the period of darkness succeeding illumination. Again, owing to the minute concentration, the chemical result in any one dark period cannot be measured. But by employing rotating sectors a large number of identical decay periods may easily be integrated to provide the information required.

The labelling of atoms in a molecule by using isotopes—radioactive and non-radioactive—has now assumed a familiar place in chemical laboratories. Deuterium is employed in all suspected cases of hydrogen atom lability and for acid-b catalysis, enolization, mutarotation and the li Isotopic oxygen, though less plentiful, provides key to debated mechanisms of hydrolysis and constitution of bound oxygen atoms in molecu Already nitrogen isotopes have indicated the r at which nitrogen molecules are severed synthetic ammonia catalysts. In fact, progress this field is only limited by the rate at wh isotopes may be produced, and the variety reactions by the kinds of isotopes available.

In principle, radioactive indicators are used the same way. They have the advantage of be easy to detect in small quantity, but often h practical limitations in their short life-times. T practical disability, however, can be overcome using more powerful neutron generators. T question of the ionization of carbon-halogen bo has been tackled in this way, and the biologi applications of radio-phosphorus are becom widely known

Thus within a matter of a few years a n branch of physical chemistry has come into bei The principles of the subject are now well est lished, and it will not be long before every bra of chemistry will derive benefit from these advan in physico-chemical technique.

THE RELATIONSHIP BETWEEN PITHECANTHROPUS AND SINANTHROPUS

By Dr. G. H. R. von Koenigswald, Bandoeng, and Prof. Franz Weidenreich,
Peking Cenozoic Research Laboratory, Peiping Union Medical College, Peking

DAVIDSON BLACK had remarked on the great similarity between the first skull of Sinanthropus to be found and the Pithecanthropus skull of Trinil, a condition which induced him to see in Pithecanthropus a Hominid form closely related to Sinanthropus (1931). The additional finds of the latter, unearthed in the interval, have confirmed Black's interpretation in every respect. But on the other hand, since the Pithecanthropus finds remained restricted to that rather incomplete specimen of Trinil, absolute evidence for his true Hominid character was lacking. In such circumstances, there was no other way open but to await the discovery of additional Pithecanthropus material before definitely solving this problem.

These discoveries materialized. Following the recovery of a rather primitive infantile skull (*Homo modjokertensis*) in 1936 and of a lower jaw of an adult individual, one of us (G. H. R. von K.), during 1937, discovered a skull in the undoubted Trinil deposits of Sangiran. This skull, preserved up to the basal region, conforms in every resp as to size, shape, and details to Dubois's Tri specimen. Dubois, however, opposed the attri tion of this skull to Pithecanthropus. Nevert less, the details of the interior, as well as exter surfaces of the skull, and also the skiagra delineating the otherwise indistinct sutures a breakage lines, show not the slightest trace irregularity or deformation, such as would unavoidable if the assembly of the fragments h been artificially adapted to a particular form. this skull of Sangiran was added another sk fragment derived from the same deposits and of t same site during the summer of 1938, brie described in NATURE of October 15, 1938, p. 7 by us. We are now in a position to report on additional Pithecanthropus find made this ye It concerns the lower part of an upper jaw unusually large dimensions, comprising the p cessus alveolares of both sides with complet preserved nasal floor and palate, the complete l ıtal arch with all the teeth leading from the ıine backward, and a part of the right dental h up to the first molar. The incisors were lost, t their alveoli are preserved (see accompanying roductions, *a* and *c*). Afterwards the skull longing to this jaw was also found. It comprises posterior third of the brain case, including the tire basis.

Morphologically and geologically, we believe we justified in attributing all these finds to hecanthropus. This type is thus represented by following finds:

(1) Skull of Trinil (Dubois, 1891): Pithecan-opus skull I.

(2) Mandible of Kedung Brubus (Dubois, 91): Pithecanthropus mandible A.

(3) Juvenile skull of *Homo modjokertensis* eol. Survey 1936)*.

(4) Mandible of Sangiran (v. Koenigswald, 36): Pithecanthropus mandible B.

(5) Skull of Sangiran (v. Koenigswald, 1937): thecanthropus skull II.

(6) Skull fragment of Sangiran (v. Koenigswald, 38): Pithecanthropus skull III.

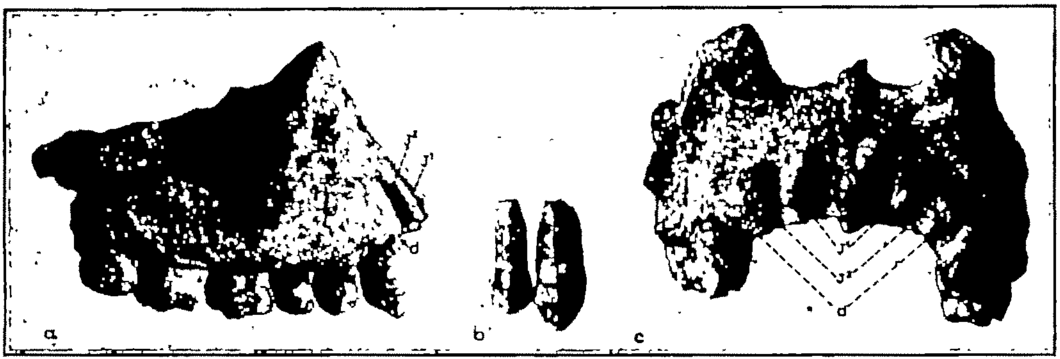
(7) (*a*) Maxilla of Sangiran (v. Koenigswald, 39); (*b*) Skull fragment of Sangiran (v. Koenigs-ld, 1939): Pithecanthropus skull IV.

The Sangiran skull (Pithecanthropus skull II) embles the Trinil skull as closely as one egg other. The former (skull II) is only slightly aller than skull I—its capacity being 835 c.c. as mpared with 914 c.c. of the Trinil skull—but its rietal and occipital parts are relatively broader. e Sangiran fragment (Pithecanthropus skull III) in its preserved part, not so flat as the other o (skulls I and II), but otherwise resembles them every detail. In addition, it bears a distinctly onounced crista sagittalis.

Of the Sinanthropus cranial material, skulls E and II of Locus L are most suitable for a comparison, having capacities of approximately 915 c.c. and 1015 c.c., respectively. These skulls are slightly larger than the Pithecanthropus skulls, but they are the same in general form and particularly in height.

The main differences so far as the skull cap is concerned consist in that in Pithecanthropus (skulls I and II) the supraorbital tori pass directly over to the extraordinarily flattened forehead, whereas in Sinanthropus the supraorbital ridges are much more demarcated from the tuber-like vaulted but otherwise also strongly receding forehead. On the other hand, the obelion region in Sinanthropus is flat, while in Pithecanthropus it is rounded off. The greatest similarity is seen in the general form and structure of the temporal and occipital bones, and there is absolute conformity in some special details of these bones. The Pithecanthropus fragment III and Sinanthropus skull E show identical features even in apparently unessential structures. Beside the first mentioned sagittal crest, there is in the obelion region on each side of the sagittal suture a short groove which Black described and illustrated in Sinanthropus skull E.

With regard to the lower jaws, that from Kedung Brubus is characterized as representing Pithecanthropus by the exclusively basal location of a broad digastric fossa—the only usable criterion. This mandible corresponds in size and proportions to the small female Sinanthropus jaws A and H, and the mandible M II, more recently discovered, and not yet described. The jaw from Sangiran (Pithecanthropus mandible B), on the other hand, is large, and corresponds to the large male Sinanthropus jaws G I and K I, with the exception that the frontal section is considerably thicker than in the latter.



(*a*) UPPER JAW OF A MALE PITHECANTHROPUS (SANGIRAN, JANUARY 1939), VIEWED FROM THE RIGHT SIDE *d*, DIASTEMA; J^1, ALVEOLUS OF J^1; J^2, ALVEOLUS OF J^2. ½ NAT., SIZE.

(*b*) UPPER RIGHT CANINE AND FIRST PREMOLAR OF A MALE INDIVIDUAL OF SINANTHROPUS (*F*IV), SO AS TO DEMONSTRATE THE PROTRUSION OF THE CANINE. ½ NAT. SIZE.

(*c*) THE SAME AS (*a*) BUT VIEWED FROM IN FRONT. ½ NAT SIZE.

On the basis of my study of the original, I have now come to the clusion that this infantile skull really represents a Pithecanthropus d. I shall report on this elsewhere.—F.W.

The upper jaw from Sangiran (see reproductions) has as yet nothing comparable among the Sinanthropus specimens, for the two upper jaw fragments of the latter known up to the present have much smaller dimensions and proportions, implying that they belong to female individuals, while the upper jaw from Sangiran must be ascribed to a male.

The differences in size and proportions of the upper and lower jaws of both Pithecanthropus and Sinanthropus, apparently chiefly due to sexual differences, also serve as a criterion of the cranial conditions in this respect. The lower and upper jaws from Sangiran are much too large for the small Pithecanthropus skulls I and II, whereas the lower jaw fragment of Kedung Brubus would seem to fit them better. It may be concluded, therefore, that the two Pithecanthropus skulls, regardless of their minor differences in size and thickness, must have belonged to female individuals, whereas the rather heavy Pithecanthropus skull IV represents undoubtedly an old male individual.

With respect to the dentition, the Pithecanthropus molars are larger than those of Sinanthropus available so far. But the lower incisors—so far as the size of the crowns can be estimated from that of the alveoli—and especially the lower canines of Pithecanthropus, are decidedly smaller than those of Sinanthropus. The canines of the Pithecanthropus upper jaw (see reproduction *a*) protrude considerably beyond the premolars, despite the fact that both are much worn. They conform in this respect to the Sinanthropus canines (see *b*) so far as male individuals are concerned. The pattern of the Pithecanthropus canine resembles that of Sinanthropus, but is less complicated by lacking the cingulum so characteristic of the latter. These differences are also true for the premolars and molars, in so far as no one of these teeth in Pithecanthropus shows such primitive characteristics as are found in Sinanthropus. Pithecanthropus, therefore, undoubtedly stands in this respect at the upper limit of the range of variation approaching the Neanderthal types. On the other hand, in respect to other features, Pithecanthropus is of a more primitive nature than Sinanthropus: for example, the second molar of both upper and lower jaw of Pithecanthropus is distinctly larger than the first, and the third lower molar the longest of all three. In addition, it is evident that—the first example of a fossil Hominid known hitherto—the upper canines of both sides are separated from the lateral incisors by a broad diastema, the width of which amounts to 6·2 mm. on the right side (*d*, in reproductions *a* and *c*). This width comes close to the average width known for male gorillas and corresponds to that of the male orang (average width, according to Remane, 6·8 mm. and 6·2 mm. respectively).

The dental arch of the Pithecanthropus up
jaw is long and relatively narrow. The front tee
according to the alveoli, were ranged within
curved line and directed forward, whereas
molars form two straight and backwardly diverg
rows. Thus, all the skeletal remains and teeth
Pithecanthropus and Sinanthropus so far availa
prove the close general relationship between
two types.

With respect to the affinity of the Pithec
thropus femora—that is to say, the so-called Tri
femur, and the five femora afterwards recovered
Dubois and also attributed to Pithecanthropu
it must be taken into consideration that the se
femora of Sinanthropus, most of them represent
only by shafts, show significant differences w
compared with those femora. All of the Sin
thropus femora display, among other characte
tics, a marked degree of platymeria, and at
same time a very low pilaster index; while
supposed Pithecanthropus femora show no indi
tion of this kind, and are in all respects identi
with those of modern man. All this points against
probability of their belonging to Pithecanthrop

Pithecanthropus and Sinanthropus undoubte
represent the most primitive Hominid forms kno
hitherto, which, according to Boule, may be rang
collectively under the name Prehominids. Which
the two types must be taken as the more primiti
cannot be decided with absolute certainty for
present. Fragments of Sinanthropus skulls sugg
that this type includes also specimens the ca
cities of which did not exceed that of Pithec
thropus II—as, for example, Sinanthropus skul
—and, on the other hand, those with a very lo
and rather low cranium, as the Sinanthrop
skull fragment H III. Nevertheless, it is cert
that Pithecanthropus shows some significa
characteristics which must be considered m
primitive than those evident in Sinanthrop
especially the presence of a diastema in the up
jaw.

Considered from the general point of view
human evolution, Pithecanthropus and Sin
thropus, the two representatives of the Prehomi
stage, are related to each other in the same way
two different races of present mankind, which m
also display certain variations in the degree
their advancement.

The Prehominids are separated from the Ne
derthal group by a considerable gap. On the oth
hand, an apparently close relationship exi
between Pithecanthropus and *Homo soloensis*,
skulls of the latter appearing like an enlarg
form of the former. Certain peculiarities
Pithecanthropus reappear in exactly the sa
form in *Homo soloensis*. Those traits which su
gest an already more advanced type, like

ter cranial capacity, and several other struc- l features, can be derived directly from ecanthropus, and correspond to the condition he Neanderthal stage already attained by o *soloensis*. The two available fragments of tibia of *Homo soloensis* show no special liarities, with the exception of a pronounced ymeria, exhibiting only recent human char- rs in their general form and in details.

ne finds reported herein show that Java has me the most important centre for the study rehominid forms. Not only Prehominids, but the following evolutionary stage, *Homo nsis*, are represented there. Furthermore, we know that the Wadjak man of Java represents another early form of recent man, whose upper jaw (Wadjak II) displays in some respects a most surprising resemblance to the Pithecanthropus upper jaw.

In conclusion, we wish to express our gratitude to the officers of the Government of the Netherlands East Indies, and the Carnegie Institution in Washington for their generous support, which made possible not only the more recent investigations in Java itself, but also our joint study, conducted in the Cenozoic Research Laboratory, Peiping Union Medical College, Peking, of recently obtained Pithecanthropus material.

A NATIONAL ATLAS OF BRITAIN

By Prof. E. G. R. Taylor, Birkbeck College, London

ROPOSALS for a National Atlas of Great Britain and Northern Ireland were first put for- l from Section E (Geography) of the British ociation at the Cambridge meeting in 1938. They with a warm response from several other ions, with the result that a representative mittee got to work and was able to present a iminary plan for the Atlas in the form of a rt to the Association at its Dundee meeting, h has been already noticed in NATURE*. Just re the break-up of the meeting, a joint dis- ion of the report by interested sections took e, and it is here proposed to outline the ideas erning the Atlas which emerged during this ussion. As will presently appear, many blems still await solution, but these can fruit- y be examined during the period in which e active steps must wait upon the national rgency.

ut in the briefest possible terms, a National s aims at the cartographical representation of physical circumstances of the national territory h as surface configuration, structure, hydro- , mineral deposits, animal life and plant cover), by side with the circumstances of human ipancy (such as land use, fisheries, mining and istrial enterprises, lines of communication, ribution of population, of occupations, of ndaries, of amenities). Neither physical nor ian phenomena are static, and many present- distributions bear the imprint of the past. ice the plan necessarily embraces a certain iber of historical maps, and even pre-historical, ı, for example, as the map of Roman Britain, the map of Pleistocene Glaciation.

While the term 'National' as used in the title carries in the first instance the obvious meaning that the maps are limited to national territory, it possesses also a secondary but very important significance. A National Atlas, if it is to justify publication, must be national in its appeal and in its use. The selection of material and the choice of cartographical technique must be made with the intelligent citizen as well as the scientific investigator in mind. This does not imply a so-called 'popular' style of presentation, for fortunately the last twenty-five years have seen a great advance in the general appreciation of maps. At one time only the gazetteer type, limited to the expression of location, was understood. To this was later added the map showing local conditions: the topographical map, or the daily weather map. More recently still, as may be observed from the appearance of examples in the daily press, distribution maps, usually statistically based and limited to a single phenomenon, have become acceptable; such, for example, are maps of agricultural output, of population density, or of ethnic elements. In brief, the language of the map has become a familiar one.

It is well to remark, however, that Government departments lag far behind the general public in this respect. The enormous volumes of statistics which they collect are rarely, if ever, illuminated by being plotted in map form. Indeed, they are often summarized and tabulated in ways that obscure geographical facts of great significance. It is, in fact, true of statisticians and economists as a body that, up to the present, they have neglected or even rejected the use of maps, and it will be very regrettable if their co-operation is

---

TURE, 144, 702 (1939).

not secured in the proposed Atlas. The contention that the map can show nothing that the column of figures does not already reveal is easily refuted, although it may readily be admitted that the measure of interpretation and interpolation involved in drawing a map results in a loss of rigid mathematical accuracy. The subjective element is, however, being steadily reduced as cartographic technique advances, and all scientific workers who make customary use of distribution maps are aware that these can prove richly suggestive of new lines of investigation. Among such workers the economic historians appear as recent recruits, and the maps compiled from the statistical records of Domesday Book will provide not the least striking plate in the National Atlas.

It will be a very real gain and a very real economy to find within the pages of a single folio or pair of folio volumes the results of work in widely different fields, geological, meteorological, ecological, economic, and so on, uniformly displayed in such a way as to assist comparative study. Facts that must be sought in a score of publications, maps that, if they exist at all, are drawn on every possible projection and scale, will here be made immediately accessible, and such an Atlas, besides providing an instrument of research, will also serve as an indispensable work of reference, affording material information to the industrialist, to the social worker, to the administrator, to the regional planning authority, to the man of affairs.

The usefulness of the National Atlas will not, indeed, be called in question. Doubts may arise as to whether the material is available for so comprehensive and so complex a publication. In fact a very great body of material, very diverse in character, already exists in map form, and only awaits transference to uniform base maps. A further great body exists in statistical shape, and its actual mapping demands no more than the services of a trained cartographer. There remain, however, a number of desirable maps which must be the subject of research: a lithological map, for example, a water supply map, a smoke pollution map, maps of accessibility of individual town road and rail. Yet others depend upon data are only very slowly accumulating: a map o distribution of soils, for example, or, in another field, a map of the distribution of names, which throw so clear a light on settlement. Many such maps, if they ca drawn at all, must be partial and tentative, in an Atlas intended for general as well a specialist use, they will demand very ca cartographical treatment if they are to be from *suggestio falsi*.

Of quite another character is the diffic arising from the territorial division of the is of Ireland into two separate political unit which only one is part of the national terri of Britain. The unit of area for topograph climatological, and many biological map obviously the British Isles, but official statis and certain official maps (those of the Ordn Survey, for example), stop short at the boun of Northern Ireland. It is too early to say whe some form of co-operation with Eire may eventually be achieved.

In very many cases, of course, separate m of England and Wales as one unit, and of Scot and Northern Ireland as another, will be ap priate, and the basic scale of one to a mil (1/*M*), involving a page size of approxima 21 in. × 14 in., has been chosen with this p in view. The use of an identical base map, suit enlarged or reduced in scale, for every map in Atlas, intended to facilitate rapid and exact c parisons between one distribution and anothe a cardinal feature of the plan.

It will be abundantly clear that only by wil co-operation among scientific workers wh material lends itself to cartographic exposi can a worthy National Atlas be eventu achieved. Pending the reorganization of Atlas Committee, which it is hoped will be long delayed, the present writer will be ha to act as a clearing house for suggestions ideas.

OBITUARIES

Prof. R. A. Sampson, F.R.S.

WE regret to record the death of Prof. Ralph Allen Sampson, Astronomer Royal for Scotland and professor of astronomy in the University of Edinburgh during 1910–37, which took place at Bath on November 7.

Sampson was born in County Cork in 1866. From the Liverpool Institute he entered St. John's College, Cambridge, graduating in 1888 as third wrangler. Two years later he was awarded a Smith's Prize, and a fellowship of his College followed immediat Between 1889 and 1891 he was a lecturer in ma matics at King's College, London, returning in latter year to Cambridge as the first holder the newly-endowed Isaac Newton studentship. 1893 he went to Newcastle-on-Tyne as professo mathematics in the Durham College of Science, two years later he succeeded to the chair of mat matics in the University of Durham, which bec in 1908—a restoration after some years of abeya he chair of mathematics and astronomy. In 1910 npson migrated still farther north, succeeding Sir nk Dyson, on the latter's transference to Green- h, as Astronomer Royal for Scotland and professor astronomy in the University of Edinburgh.

ampson's greatest work was his theory of the r great satellites of Jupiter. This immense under- ing, which involved the discussion of thousands clipses of the satellites and demanded qualities of severance and patience in addition to mathe- tical powers of the highest order, engrossed his ention for more than a quarter of a century. The ervational material he used fell into two categories: old observations made visually, and (2) the tometric observations of the gradual disappear- es of the satellites in eclipse, made at Harvard ween 1878 and 1903. Although the general thematical theory did not appear until 1921 (*Mem.* *. Astr. Soc.*, 63) the University of Durham under- k in 1910 the publication of the "Tables of the ur Great Satellites of Jupiter", and in the previous r Sampson's discussion of the photometric ervations appeared in vol. 52 of the *Harvard* *nals*. For these researches he was awarded in 1928 Gold Medal of the Royal Astronomical Society.

ampson's first research (1894) was on the "Rota- n and Mechanical State of the Sun". At an early ge he became convinced that a satisfactory theory the distribution of temperature in the interior of sun was essential to his purpose. He discarded principles of convective equilibrium and at- pted a discussion of temperature conditions by ans of simple hypotheses governing radiation and orption—twenty years before the foundations of mic physics were laid. In this work Sampson was rue pioneer. In 1900, he edited J. C. Adams's ctures on the Lunar Theory" and, later, the Adams nuscripts relating to the discovery of Neptune.

ampson's most valuable contribution to astronomy ing his directorship of the Royal Observatory in inburgh was his work on measuring the effective peratures of the stars. During this period, too, was greatly interested in the performance of clocks l he contributed many papers on this subject to Royal Society of Edinburgh.

ampson was elected to the Royal Society in 1903. m 1915 until 1917 he was president of the Royal ronomical Society and for many years he acted secretary of the Royal Society of Edinburgh. He d the honorary degrees of Sc.D. and LL.D. of rham and Glasgow respectively, and in 1921 he s elected a corresponding member of the Bureau Longitudes (Paris). He is survived by his wife, son and four daughters. W. M. Smart.

Prof. R. V. Wheeler

ichard Vernon Wheeler, director of the ety in Mines Research Stations, professor of fuel hnology in the University of Sheffield and editor *Fuel in Science and Practice*, died at his home in ffield on October 28 at the age of fifty-six years.

graduated in the University of Manchester in 1903, where as an undergraduate he had already joined the band of research workers who laid the foundations of our present knowledge of flame and combustion, the famous Manchester school which will always be associated with the names of H. B. Dixon, W. A. Bone and R. V. Wheeler.

Wheeler became one of the leading authorities on safety in mines both in Great Britain and abroad, being awarded the Gold Medal of the Institution of Mining Engineers in 1937, and also one of the leading fuel technologists, receiving the Melchett Medal of the Institute of Fuel in 1938, but he always remained at heart a research worker. Having little use for the *ad hoc* and empirical type of research, he was fortunate in having the ability to convince those responsible for the organization and financing of the researches over which he had control of the importance and value of long-range and fundamental research. This ability was largely due to the clarity with which he explained complex problems to the non-scientific or non-technical man. As a result he was enabled to build up teams of research workers who have carried out extensive investigations in each of the fields of work in which he was interested.

In dealing with some of the most important problems involved in the winning and utilization of coal, namely, dust explosions, spontaneous combustion, carbonization and industrial burning, Prof. Wheeler regarded a knowledge of the constitution of coal as being of prime importance. This was emphasized in the "Monograph on the Constitution of Coal" written by him and Dr. M. C. Stopes and published by the Department of Scientific and Industrial Research in 1918. In this publication, which greatly stimulated research in this field, they summarized critically the work already done, and surveyed the ground to be covered by future workers. Wheeler took a prominent part in the development of this work with the assistance of many collaborators, and the main results are to be found in a series of twenty-five papers in the *Journal of the Chemical Society* under the general heading of "Studies in the Composition of Coal". The application of these researches to the more technical problems was well brought out in a series of papers published in the technical press. In his work on the prevention of gaseous explosions he emphasized similarly the importance of a fundamental knowledge of the mode of ignition and combustion of gaseous mixtures. The outstanding work in this direction was published in papers in the *Journal of the Chemical Society* dealing with the ignition of gases and with the uniform movement during the propagation of flame. The justification of his long-sighted policy is again shown by the important series of papers in the technical press showing how this knowledge could be applied.

Despite the wide range of the subjects of these researches, Prof. Wheeler always took keen interest in every piece of research under his direction, large or small, and was a continual source of suggestions and advice. He was an extremely hard worker, his enthusiasm for his work was infectious and he earned the esteem and respect of all those fortunate enough to work under him.

No account of Prof. Wheeler would be complete without reference to the respect and affection felt for him by the mining community, men as well as masters, to whom his name was a household word. His staff at the Buxton Research Station of the Safety in Mines Research Board treasure the tributes paid to him by colliers visiting the Sunday 'demonstrations', referring to him, for example, as "the greatest friend of the miner since Sir Humphry Davy".

W. PAYMAN.

Vice-Admiral Sir Percy Douglas, K.C.B., C.M.G.

VICE-ADMIRAL SIR PERCY DOUGLAS, who died on November 4 at the age of sixty-three years, joined the surveying branch of the Royal Navy in 1898 and at once showed marked aptitude for this type of work. He possessed an alert brain and was more than a little interested in 'gadgets'; anything which could relieve the labours of the surveyor in the field was of particular interest to him, and being of an inventive turn of mind, he did a great deal to lighten their work and expedite production.

Whilst in command of H.M.S. *Waterwitch* on the China Station and in collaboration with the late Commander J. Sharpey-Schafer, Douglas introduced the Douglas-Schafer sounding gear, which was a great advance on former methods of sounding in comparatively shallow water; later he was responsible for the Douglas protractor and, jointly with Prof. R. Appleyard, perfected the arcless sextant. During the War of 1914–18, Sir Percy was appointed to serve as hydrographic surveyor on the staff of the Vice-Admiral, Aegean, and at a later stage in the same capacity with the Flag Officer at Dover; between these two appointments he was the first director of the Naval Meteorological Service.

His knowledge of hydrography and geodesy was of the greatest assistance in the Dardanelles campaign, and also in the attacks on the Belgian coast, where indirect fire and bombardment was of such importance and where sound-ranging was developed to meet the need for the accurate bombardment of enemy gun positions.

After the War, Admiral Douglas interested himself in the development of echo sounding apparatus, and it was largely due to his initiative that the Admiralty echo sounding gear was perfected and brought into use. In addition to his official duties as hydrographer of the Navy, Sir Percy was, during his term of office, an *ex officio* member of the National Committee for Geodesy and Geophysics of the Royal Society, and served on the Council of the Royal Geographical Society.

Sir Percy became a member of the "Discovery" Committee in 1925 and his wide experience and knowledge were of immense benefit to this body. Shortly after his retirement he was appointed by the Board of Trade to be acting conservator of the Mersey and somewhat later became chairman of the Dover Harbour Board.

Sir Percy was a fellow of the Royal Astronomical Society and of the Royal Geographical Society a Younger Brother of Trinity House. At the t his death he was serving as Commodore Sup tendent of the Dockyard at Dover.

J. A. EDGE

Dr. T. L. Prankerd

IT is with deep regret that we record the t death in a street accident, on November 11, o T. L. Prankerd, for many years lecturer in bota the University of Reading.

Theodora L. Prankerd was born in 1878 at I gate, the daughter of Dr. O. R. Prankerd. She educated at Brighton High School and the R Holloway College whence she graduated in scien the University of London. Later she was appoi to the staff of Bedford College (University of Lon and then proceeded to carry out her early bota researches at the University of Chicago. In she was appointed lecturer in botany in Unive College, Reading, where she remained until College received its Royal Charter in 1926, and she continued as lecturer in the University up t time of her death. She was admitted fellow o Linnean Society in 1919.

Dr. Prankerd's botanical researches were ch terized by unlimited patience and exactitude. earlier work was morphological. In her first pap the water violet, Hottonia, interest centres in anatomy and possible phylogeny; and this o out more strongly in her next paper on a coal seed of which she gave a very careful descrip Although her interest remained largely morpholog her other published papers are concerned with perception of the stimulus of gravity by organs, reveal a great number of patient experiments. ardently supported the theory of statolith percep and although many consider that this conflicts the hormone theory, she herself was trying to com the two into a comprehensive theory of percep and transmission.

But it will not be as a research worker so muc a teacher and friend that Dr. Prankerd will remembered. Hosts of students have passed thr her hands. Nothing was too much trouble for and many a student will recall with gratitude kindly help which she always offered; and was not confined solely to study. She took a pers interest in her students.

Dr. Prankerd had a keen sense of justice would stop at nothing in her efforts to make jus prevail whether for an ideal or an individual. that reason she was sometimes judged harshly others though never by anyone who was prepare probe beneath that veneer of seeming forcefuln for then they found a kindly and sympathetic wom He or she who finally gained her friendship s realized how intensely loyal she was. She wa woman, too, of great breadth of vision and l ideals. Thus, her life was not devoted solely to plants. She was a great advocate of peace, and efforts for the League of Nations Union were tirel e was also an artist of no mean calibre. She had ny delightful water-colour sketches to her credit. r literary tastes were often reflected in her lectures, ich, though not always easy to follow, were elight to hear.

Hers was such a personality that she will be membered affectionately by many of her former dents when some of their more brilliantly scientific l successful teachers have been forgotten. It is irony of fate that a woman who argued and rked for peace so unflinchingly should have met death on Armistice Day.

Dr. Prankerd leaves her mother to whom she was voted and to whom our deepest sympathies are ended.

WE regret to announce the following deaths:

Prof. F. Angell, emeritus professor of psychology in Stanford University, on November 2, aged eighty-two years.

Prof. Charles Barrois, formerly professor of geology in the University of Lille, on November 8.

Mr. C. J. Bond, C.M.G., a former member of the Industrial Health Research and of the Medical Research Board, on November 23, aged eighty-three years.

Mr. Wilfred Trotter, F.R.S., sergeant surgeon to H.M. the King, and consulting surgeon at University College Hospital, on November 25, aged sixty-seven years.

NEWS AND VIEWS

hecanthropus and Peking Man: Comparative Studies

By a happy and fruitful conjunction in comparative dy of old and new material, Dr. G. H. R. Koenigs-ld, of Bandoeng, Java, and Prof. Franz Weiden-h of the Peking Cenozoic Research Laboratory, able to record in another column of this issue of TURE (see p. 926) some remarkable observations ring on the relationship between those early fossil ninids, or precursors of man, Pithecanthropus of a and Peking man. In the further light now own upon the problem of the descent of man by nt discoveries of both Sinanthropus and Pithecan-opus—of the former, some still undescribed, of the er, some of the more important made only in the rent year in response to intensified search—the hors demonstrate by detailed comparison not only essentially human affinities of Pithecanthropus, ich Dubois, its first discoverer, has come to ques-n, but also the very close affinity of Pithecan-opus to Sinanthropus, of whose right to stand in line of human descent no doubt has ever been sed. Further, among the latest Pithecanthropus terial to be discovered is an upper jaw, which in separation of canines from incisors presents a racter hitherto regarded as distinctively Simian. appearance of this character in Pithecan-opus is notable as it has been adduced as an ument in discussion of the Piltdown jaw. By far most interesting and significant result to emerge however, not so much the affinities of the two ups of fossil remains as their differences, in which only now one now the other exhibits an approach modern man, but these differences also indicate t the variability, which is so marked a feature in individual specimens of Sinanthropus, is almost ally striking when the two groups are compared h as a whole. In other words, there is evidence n at this comparatively early stage of human lution of a variation which may be termed racial. the authors' pregnant allusions to the position of *Homo soloensis*, no more need be said here than to express a confident hope of further light from an equally fruitful collaboration.

Anthropometry and the War

IN a written reply in the House of Commons under date September 28, to a question in reference to offers from ex-officer anthropologists to conduct an anthropometric survey of H.M. Forces, Sir Victor Warrender, financial secretary, War Office, stated that he was advised that "though such a survey might be of scientific interest, it is impossible in present circumstances to carry it out, owing to the time which would be required for the purpose". Captain A. G. Pape, by whom the attention of NATURE has been directed to the passage in *Hansard* reporting question and author (September 28, 1939, p. 1516), writes strongly urging the need and advantages of such a survey, which, he informs us, he himself had suggested to the authorities with the offer of his services. Readers of NATURE will scarcely need to be reminded of the deplorable gap in evidence relating to the constitution of the British population, owing to the lack of systematic records of physical characters and other anthropometric data. The survey contemplated by Captain Pape, however, is apparently of a far more extensive character, and would include observations demanding the services of medical and psychological specialists, and an extension to the rising generation through an organization embracing both university and school. Strong though the argument for an anthropometric record of the population may be—the need will be much more insistent when post-war measures of social amelioration have to be considered—it is probably quite inevitable that in so far as regards H.M. Forces, the time factor is all-decisive. While opportunity might possibly be found to examine troops serving in the field or in training, these subjects would not be representative of an average sample of the population; and the measurement and recording of the minimum observations of any value of men as they are brought up for enrolment in the Forces, who would more nearly approach the standard of the general population, would overburden the medical officer, who already protests against the inadequate time allowed for individual examination owing to pressure of numbers.

The Settlement of Europe

THE admirable broadsheet "European Order and World Order" issued by Political and Economic Planning (P E P), a summary of which appears on p. 948 of this issue, should go far to clarify the confusion which has resulted from the use in current discussions of such terms as 'war aims' and 'peace aims'. The terms on which the belligerent powers will make peace can scarcely be usefully discussed until the outcome of the war is known. On the other hand, neutrals as well as belligerents will have to consider far-reaching measures for reconstruction and for establishing a new international order. This post-war question of reconstruction requires immediate discussion and study if a settlement which is both technically possible and politically acceptable is to be found. No international conference can be expected to do more than put into final form and ratify measures which have already been worked out by experts and approved by the political advisers of all the countries concerned. Moreover, it is neither necessary nor desirable that the reconstruction problem should be tackled simultaneously with that of establishing peace. Indeed the former is visualized usually as a long-term problem for which appropriate machinery must be kept in being over a term of years rather than weeks. The fact that P E P has thought it worth while to issue a broadsheet upon these problems indicates that they are already receiving serious, if unofficial, attention. It is at least encouraging that so many new minds are being brought to bear upon them and so many new ideas are being sifted and taking shape. The scientific and constructive approach outlined by Political and Economic Planning claims the closest attention by scientific workers, and may well help them to see in what direction their own contribution can most effectively be made.

Association of Scientific Workers

THE annual council meeting of the Association of Scientific Workers was held in London on November 25. In the report submitted by the Executive Committee, the activities of the Association during the past year were reviewed. These included general activities before the War, such as the Legal Committee and the Scientific Films Committee, and special activities since war broke out, which included the collection of information on the effect of the War on science and scientific workers. The Executive Committee had drawn up a tentative scheme for the setting up of a State Department for the Co-ordination of Science and had submitted this scheme to a number of scientific bodies for their comment; these bodies had in general replied that they could work in this way to improve the status of scien A net increase in membership of 25 per cent dur the last year was also reported. The president of Association, Prof. F. G. Donnan, in his address the meeting, stressed the necessity of building activities that would have an economic appeal potential members of the Association, and sugges the possibility of establishing an unemploym benefit fund. The Association, in trying to repres men of science of all subjects in one body, ha great task before it, and in view of the existenc many sectional organizations for men of science must offer strong inducements to gain members.

THE general feeling of the membership that Association *should do a great deal more in the d* to-day economic interests of the scientific work particularly those in industry, was expressed in unanimous adoption of a resolution: "That steps taken to ensure that the primary purpose of Association is to effect the organisation of scienti since any satisfactory co-ordination of science depe upon an adequate organisation of scientists". deep concern felt by members of the Association the rapidly increasing disorganization in scien work throughout Great Britain was expressed in discussion of two further resolutions, and whil was carried by a majority vote that the Associa should not press for a Ministry of Science in present circumstances, the Executive Commi was instructed to press for the establishment c national council consisting of representative scien and technical personnel, which would have the ob of achieving adequate organization and full use of scientific resources of the country. The follow officers were elected for the year 1939–40: *Presid* Prof. F. G. Donnan; *New Vice-Presidents*, P P. M. S. Blackett, Prof. D. Keilin; *Hon. Gen Secretary*, Dr. W. A. Wooster; *Hon. Treasurer*, L. Klatzow.

New International Hormone Standards

IT was stated in NATURE of May 13, 1939, that Third International Conference on the Standard tion of Hormones, held at Geneva in 1939, decided that international standards should established for certain hormones of the anterior of the pituitary gland and analogous substances fo in urine and serum, and that international u should be defined in terms of a weight of each s standard. It was further decided that the final paration of these standards, their dispensing i form suitable for the use of the laboratory wor their storage, preservation and subsequent distr tion should be undertaken by the National Insti for Medical Research, Hampstead, London. first of these new standards, as announced earlie the year, namely, that for the gonadotrophic s stance of human urine of pregnancy—chori gonadotrophin—was established in May of this y The preparation of two additional internati standards has been completed, namely, for nadotrophic substance of pregnant mares' serum d for the lactogenic (crop-gland stimulating) sub- nce of the anterior lobe of the pituitary gland. e former standard has been prepared from sub- ntial amounts of material generously provided by e manufacturing firms in four different countries, d the latter from material supplied by seven manu- cturing firms and two research institutes in five ntries. In the case of each standard the individual nples were examined by members of the Conference d a suitable mixture was then made to serve as e respective international standard, and finally pensed in the form of tablets which have been cked in sealed tubes. In the case of each standard, ch tablet contains approximately 100 international its.

THE international standard for the gonadotrophic bstance of pregnant mares' serum is dispensed in e form of 25-mgm. tablets, each sealed tube con- ning ten of the tablets, and the international unit s been defined as the specific gonadotrophic tivity contained in 0·25 mgm. of the standard eparation. The international standard for prolactin dispensed in the form of 10-mgm. tablets, each led tube containing ten of the tablets, and the ternational unit has been defined as the specific tivity contained in 0·1 mgm. of the standard eparation. As in the case of the international ndards for other hormones, drugs and vitamins, e above international standards are held, on behalf the Health Organisation of the League of Nations, the National Institute for Medical Research, mpstead, London, N.W.3, and are distributed erefrom to national control centres established in her countries for local distribution to laboratories, stitutes and research workers, and to workers in her countries in which the establishment of national ntrol centres has not yet been completed. With gard to the supply of these new standards to those quiring them in the United Kingdom, applications ould be made to the Department of Biological andards, National Institute for Medical Research, mpstead, London, N.W.3.

andardizing Genetical Symbolism

AT the International Congress of Genetics held at aca, N.Y., in 1932, it was resolved that the netical societies of all countries be asked to co- erate in preparing recommendations regarding the oblem of standardizing genetical symbolism, in der to discuss them at the next International netical Congress. Prof. Tine Tammes (Groningen), o was appointed to take charge of this work, pro- ced a preliminary report in conjunction with Dr. de Haan and then turned over the task to the ternational Union of Biological Sciences. This dy, together with the International Institute for tellectual Co-operation at Paris, convoked a meet- of delegates from various countries, which was d in the rooms of the Linnean Society of London August 14–15, 1939, with Prof. M. J. Sirks roningen) as chairman. The delegates were Dr. A. Establier and Miss N. Nicolsky (from the I.I.I.C. in Paris), Prof. O. Winge (Denmark), Dr. B. Ephrussi (France), Prof. H. Nachtsheim (Germany), Prof. R. R. Gates, Prof. J. B. S. Haldane and Mr. A. E. Watkins (Great Britain), Prof. K. v. Körösy (Hungary), Dr. K. Ramiah and Dr. S. N. Venkatraman (India), Prof. M. J. Sirks and Dr. S. J. Wellensiek (Holland), Prof. O. L. Mohr (Norway), Prof. M. Skalinska (Poland), Dr. O. Tedin (Sweden), Prof. F. Baltzer, Prof. A. Ernst and Prof. E. Hadorn (Switzerland), and Prof. E. W. Lindstrom (U.S.A.). The delegates from Belgium, Finland, Italy and Japan were unable to attend. A preliminary series of rules for the symbolizing of genes and chromosome aberrations was drawn up at this meeting.

Science and Ethics

IN the *Scientific Monthly* of October, Prof. E. G. Conklin discusses the question: "Does science afford a basis for ethics? The highest level of human development, he urges, is attained when purpose and freedom, joined to social emotions, training and habits, shape behaviour not only for personal but also for social satisfactions. Society, no less than the individual, is seeking satisfactions, and when all these things combine, we have what we call ethics, or the science of right conduct. Science, he considers, affords a sound basis for ethics in spite of the fact that it is regarded as natural rather than supernatural in origin and development. With increasing knowledge of Nature and man, many codes have been shown to be unreasonable and unethical, and science has helped to replace them by more rational and humane ones. Science is knowledge of Nature and of man, and ethics being dependent on such knowledge it is impossible to divorce ethics from science. Science did not create Nature or man or ethics, and cannot be held responsible for their imperfections. It is as absurd to attribute human greed, aggression, hate and war to science as it would be to hold it responsible for hurricanes, earthquakes or pestilences. Because science regards ethics as a natural phenomena, it can hope to determine the causes of unethical behaviour and attempt to improve ethics by controlling these causes.

PROF. CONKLIN thus believes that progress in the control of social disorders should be possible in the same way as in the control of bodily diseases. Science has helped to make war so terrible that sane people everywhere fear and shun it. More indirectly, science can investigate the causes of war and show how they can be removed, for war and social disorders in general can be cured only as bodily diseases are, by controlling their causes. The main hope for human peace and progress lies in the cultivation of habits that make for peace and progress, especially in the leaders of the nations. There can be no final solution of the problems which threaten the very existence of civilization except through the cultivation of a wider and more generous form of ethics. Hope for the future rests in the co-operation of science, education and religion.

Fur-trade in Northern Manchuria

THE predominance in the news of political activities in Manchoukuo tends to obscure the fact that it supports an active Institute of Scientific Research, the latest publication of which describes one of the staple industries of Manchuria, the fur trade (*Rep. Inst. Sci. Res., Manchoukuo*, 3, 227; July 1939). In a lengthy paper W. N. Schernakow describes very fully, from his own journeys in Manchuria and from the contributions of other writers, various aspects of the extensive fur-trade. The majority of the fur-bearing animals are captured by means of snares, traps, pits, as well as by firearms and poison, but sometimes hunting dogs and birds of prey are employed, and one of the illustrations actually shows a hunter in the Barga using bow and arrow. The furs are collected locally, and ultimately most find their way to the fur-market at Harbin. Here in the season 1937–38, 1,217,169 furs were sold, an increase of more than a quarter million over the sales of the previous year. The greater number represents five relatively common species: Tolai hare (*Lepus tolai*) 500,000; rat (*Rattus norvegicus caraco*) 200,000; Sansing squirrel (*Sciurus vulgaris mantchuricus*) and yellow ermine (*Mustela alpina raddei*) 100,000 each; and kolinsky (*Mustela sibirica* of various subspecies) 130,000. The rare skins represented by ten or fewer individuals at the fur-market were wolverine (*Gulo gulo*) and bear (*Ursus mantchuricus*) 10 each; leopard 5 and Manchurian tiger (*Tigris tigris coreensis*) 4. The author regards the preservation of woodland as the surest way of preserving the fur-bearing animals, and he points out that the Chinese destroy not only woodland but even brush-wood wherever they settle.

Recent Archæological Finds in Staffordshire

A NUMBER of discoveries of interest are recorded in the report of the archæological section of the North Staffordshire Field Club for the period 1938–39 (*Trans. and Ann. Rep. N. Staffs. Field Club*, 73, 1939). Among these may be mentioned a disk barrow, hitherto unrecorded, which was discovered by G. J. V. Bemrose, chairman of the section, on a hill slope overlooking the stream at Oakley. Further examination, in the course of which several well-patinated flints were found on the surface, confirmed the view that it was of the central monolith type, the site of the monolith being clearly discernible. The proximity of the Devil's Ring and Finger is considered significant, while it is pointed out that it is probable that Oakley Park drive is the site of a Romano-British road linking Chesterton (Mediolanum) with Rutunium and Uriconium. Further evidence of a Romano-British road comes from Madeley Old Manor Park, where a half-mile stretch of a 'way' has been identified. It forms part of a way, on which on a length known as Longford, between Wellington and Newport, an air photograph has shown a Roman 'castra' near Wall, superimposed on a British hill-fort and other earthworks, hitherto unknown. A Romano-British residence site at Park Springs, of which the excavation was begun by W. L. Hind in 1927, now shows that the corridor and rooms were paved with hard fired tiles, measuring 5 inc square by 1 inch thick. They had been surfaced red slip before firing. The walls were plastered decorated in fast colour-wash, which is still br after sixteen centuries in damp, loamy soil. room was decorated in various shades of green yellow. Evidence points to more than one perio occupation.

Hot Spraying of Shellac

THE high viscosity of whole shellac when liquef and the difficulty of maintaining it fluid for considerable length of time, were responsible for failure of the original experiments to melt and spra under steam pressure. We have received from the L don Shellac Research Bureau, India House, Aldwy London, W.C.2, a pamphlet describing the work d by K. E. Lalkaka in the laboratory of chem engineering of University College, London, on bel of the Indian Lac Cess Committee and under supervision of Prof. H. E. Watson. The later exp ments described were directed towards using pulv ized shellac and causing the powder to fuse by pass through a flame, the fused particles being projec upon a surface to form a well-bonded coat. various means tried for securing a steady supply the pulverized material to the flame are describ and also the development of a simple appara for carrying out the process effectively. A st has been made of the operating conditions.

MATERIALS used in protective and decorative co ings are generally used in solution or emulsion for applied by brush, spray or pad. It is found tha small amount of the solvent is invariably retained the film even after prolonged drying. This resid solvent is responsible for the poor water resista and the comparatively short life of the protect coat. In particular, shellac varnish gives films wh 'blush' when immersed in water, but a flake of shel remains clear and unaffected even after seve months of immersion. The technique of a n method is described and the following surfaces h been satisfactorily treated by the process: wo paper; tin, aluminium and copper sheet; concr glass, asbestos board, plaster castings and por stoneware. The results are published for the inform tion of all interested in this novel field of applicat of shellac.

Electricity on Board Ship

THE Institution of Electrical Engineers has j published the third edition (September 1932) of "Regulations for the Electrical Equipment of Shi (3s. 3d., cloth; and 2s. 2d., paper. E. F. and Spon, or the Institution of Electrical Enginee These regulations enumerate the main requireme and precautions for ensuring safety from fire shock, in connexion with the generation, storage distribution of electrical energy for all purposes sea-going ships of all descriptions with the except of warships. The book will be essential to ma facturers, navigators, and marine architects, and useful to all who travel by sea. It begins by giving finitions indicating the sense in which the various chnical expressions given are used throughout. n 'earth', for example, is a connexion to the general ass of the hull of a steel ship, and detailed definitions e given of words like watertight, weatherproof, etc., that the exact meaning of these words when they pear in marine contracts can be found.

FOR direct current, the standard voltages are 110 d 220, but for small vessels, like tugs, trawlers, all yachts, fishing and similar small vessels, the andard voltages are 12, 24 and 110. The regulans are fairly stringent; for example, every seaing ship in which electric power is used for essential rvices shall, except where other means are available r maintaining these services, be provided with two more generating sets of such combined output that the event of one set being disabled the remaining nerating plant shall be capable of supplying the sential services. Where electric discharge lamps luminous discharge tubes are used, lighting by one more incandescent filament lamps shall be proled as necessary to ensure safety in the event of the tinction of the discharge lamps. It must also be ranged that electric discharge lamps should operate tisfactorily with the ship inclined to the normal at y angle up to 15° transversely and 10° longitu- ally, and with rolling up to 22½° with the vertical. e also learn that lightning conductors need not be ted to steel ships having steel masts. Appendix 3 very important, as the suppression of electrical terference with radio apparatus is clearly discussed. list of devices and apparatus is given in regulation 3, which it is recommended should never be s than ten feet distant from any magnetic mpass.

ining Electrical Engineers

AT the first meeting this season of the South Wales anch of the Association of Mining Electrical gineers, held at Cardiff last month, the new branch sident, Mr. D. J. Thomas, gave his inaugural dress. He referred to the position of the colliery ctrician, who is surrounded with regulations and trictions, with equipment under his care on which ny lives may depend, unless frequently inspected, d yet he has little authority and practically no tus. The equipment also with which he is provided often passed its useful life, while much of the new ipment supplied is unsuitable for the class of work which it is put. The apparatus has to withstand gh usage, and Mr. Thomas believes that there is ufficient appreciation on the manufacturers' part t there are conditions other than purely electrical s that have to be considered. The increasing ount of machine mining performed electrically d the wholesale electrification of surface and derground equipment make the modern colliery olutely dependent upon electricity, and the mining trical engineer holds a position of very great onsibility. It is of vital importance that this uld be recognized.

British Museum (Natural History): Acquisitions

A GIFT has been made to the Department of Mineralogy of a large polished slab of thodonite and pyrolusite, both manganese minerals, from Penorebar, Callington, Cornwall, collected by the donor, Mr. Arthur Russell, president of the Mineralogical Society. A well-crystallized stilbite from Kalumpang, Ulu Selangar, has been presented by the Director of the Geological Survey of the Federated Malay States. This is the first zeolite specimen from that locality to be added to the British Museum collections. Three interesting specimens of Terra Sigillata have been presented by Mr. E. P. Bottley. Similar tablets of clay, formerly included in every pharmacopœia as an antidote for snake bites and poisons, were shaped and stamped from medicinal earth found in various localities, notably the Island of Lemnos, Greece, and Prussian Silesia. These three tablets are probably eighteenth century specimens and bear easily legible insignia and characters. They form a welcome addition to a very fine set belonging to the Sloane collection. Terra Sigillata clays and related materials, such as China clay, have very high absorptive properties which render them of value in the treatment of dysentery and cholera.

Negro Education in the United States

AMERICAN Negroes have seldom played any notable part in education. A well-documented paper book, "Special Problems of Negro Education" (Washington, D.C.: G.P.O. 25 cents), shows that coloured children suffer from an inequality of chances compared with whites. The author, Prof. Wilkerson, has made several studies of the subject, and the results are gathered in this monograph. Negroes are required by law to attend separate schools in eighteen States, from Alabama to West Virginia. Four fifths of them are in the South and supply nearly one fourth of the population. Is their education in separate schools adequate, and, if not, what can be done to improve it? These are the questions the author answers. The figures tabulated are a little puzzling, but suggest on careful examination that during 1933–34 school attendance was considerably less among Negroes than whites. The Negro schools were kept open on the whole for a shorter time, though States offer varying data. A racial difference of one school month becomes over a period of years a real handicap and leads to lower levels of scholastic achievement; pupils retarded in early grades are likely to drop out of school. Eminent authorities all agree that they are quite as good in learning ability as whites. Transportation for education is important for rural districts, and here, too, they are handicapped, while they have fewer and worse-paid teachers. These disparities have been defended, but no sensible authority doubts that they should be eliminated. In Mississippi many of the coloured schools are housed in churches, old stores and shanties and lack decent comfort and educational materials. The story of higher education is similar, but it has to be noted that the Southern States in view are unable to finance public education at a satisfactory level. A much enlarged programme of Federal aid is needed, and a recent decision of the United States Supreme Court recognizes the right of Negroes to "proper provision" of graduate and professional study. So the States must provide separate facilities for them, or admit them to their universities.

Amendments to the Therapeutic Substances Act

THE Joint Committee which administers the Therapeutic Substances Act, 1925, has issued some amending regulations (Statutory Rules and Orders, 1939, No. 1395. H.M. Stationery Office. *2d.* net). A new regulation requires that every holder of a licence to manufacture therapeutic substances, who engages in the culture or manipulation of pathogenic spore-bearing micro-organisms, shall provide separate laboratories, utensils and apparatus required for the culture or manipulation of such micro-organisms. New regulations are also imposed respecting the labelling, testing and standardization of tetanus toxoid and gas gangrene antitoxin.

Earthquake in Turkey

FOR the second time recently Turkey has been stricken by a disastrous earthquake. On September 22, the epicentre was near Smyrna (NATURE, September 30, p. 589). Now, on the morning of November 23, an intense shock destroyed at least six villages in Anatolia. Eighteen people are known to have been killed, but complete news is not yet available since telegraphic and other communications were interrupted by the earthquake.

The Night Sky in December

ON December 22 at 18h. the sun enters the sign Capricornus (the winter solstice). In the latitude of London, the night then lasts for 16¼ hours. The moon is new on December 10 and full on December 26. Lunar conjunctions with the planets occur as follows: on December 9d. 10h. with Mercury; 13d. 1h. with Venus; 18d. 10h. with Mars; 19d. 8h. with Jupiter; and on 21d. 8h. with Saturn. The geocentric distance between moon and Mercury at conjunction on December 9 is only 0·2°. Mars, Jupiter and Saturn south at about 17¼h., 18¼h. and 20h. respectively in mid-December and are therefore well placed for observation in the evening sky. Venus is also coming into visibility as an evening star and may be seen low in the south-west after sunset. Mercury is at greatest elongation (21° W.) on December 17, and it may then be seen low down in the south-east before sunrise. In the late evenings of this month, there is a fine array of stars between the eastern horizon and the meridian. The variable star, Algol (β Persei), souths at about 21¼h. in mid-December. Its change of light is most easily noticeable about 1¼ hours before and after the following epochs: December 4d. 4·8h.; 7d. 1·7h.; 9d. 22·5h.; 12d. 19·3h.; 15d. 16·1h.; 27d. 3·4h. and 30d. 0·2h. To the east of Algol, spread over an area of about 2° in diameter, is a cluster of about five hundred remote stellar systems. A member of another cluster in Gemini, for which a spectrogram was secured at the Mt. Wilson Observatory, shows a redward sl of the spectral lines equivalent to a speed of recess from the solar system of more than 14,000 miles second and indicating a distance of 135 million li years. The Geminid meteors, with their great frequency about December 10–12, have a radi point a few degrees preceding Castor. At midnight December 31, the brightest star, Sirius (mag. −1 is 4¼ min. before the southern meridian.

Announcements

IN view of the delay likely to be caused by pos difficulties in the present circumstances, writers "Letters" submitted for publication in the cor spondence columns are advised that, in gene proofs of communications will not be sent to auth outside Great Britain.

DR. GERHARD DOMAGK, who was recently awar the Nobel Prize for Physiology and Medicine for 19 has been elected an honorary member of the Pharr ceutical Association of the Hindu University Benares.

DR. JUAN JACOBO SPANGENBERG has been nc inated president of the National Department Health of the Argentine Republic in succession Dr. Miguel Sussieri, who has retired.

THE King has been pleased to grant Dr. Herb Chatley his authority to wear the insignia of Order of the Brilliant Jade conferred upon him the President of the National Government of Republic of China, in recognition of valuable servi rendered by him as engineer-in-chief of the Whang Conservancy Board.

PROF. DOUGLAS MCCANDLISH, of the Departm of Leather Industries of the University of Leeds, been appointed honorary director, and Mr. W. Atkin honorary research assistant, of the Proc International Research Laboratory.

THE Bradshaw Lecture of the Royal College Surgeons of England will be delivered at the Coll in Lincoln's Inn Fields by Sir James Walton, December 14 at 3.30 p.m. The subject of the lect will be "The Surgery of the Common Bile Duct"

A LEAGUE against syphilis and other vener diseases has been founded in Cuba under the auspi of the Cuban National Institute of Social Welfare

THE Central International Seismological Bur has removed from Strasbourg to 9, boulevard de Pyramide, Clermont-Ferrand, France, from wh address it will continue to function as hitherto.

AN Elgar scholarship in naval architecture of value of £130 per annum for three or four year now being offered. Entries close on January 15, 19 Full particulars may be obtained from the Secret of the Institution of Naval Architects, 10 Up Belgrave Street, London, S.W.1.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 945. CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

n Experiment on the Effects of γ-Radiation on the Grain Weevil

THE use of X- and γ-radiation as a means of ntrol of insects attacking stored products has never en fully investigated. We have recently made me experiments on the action of γ-rays on the evil *Calandra granaria*, which, although of only a eliminary nature, are of interest inasmuch as ey show that the control of these pests by radiation possible, under laboratory conditions at least.

Weevils were exposed to the mixed β- and γ-rays m 10 gm. of radium. The radium was contained 50 monel metal tubes 13 mm. long × 5 mm. in ameter and having a wall thickness of 0·5 mm., sely packed side-by-side to form a cylindrical slab mm. in diameter and 13 mm. deep.

One hundred adult weevils of mixed ages were put to a shallow celluloid box 40 mm. in diameter and mm. deep, provided with air holes in the lid and thin celluloid sheet 0·25 mm. thick on the under-le.

The box was placed directly over the radiation urce so that the thin celluloid underside rested on e tops of the radium tubes. On account of the low tration (0·5 mm. monel + 0·25 mm. celluloid) a nsiderable amount of β-radiation was transmitted the weevils, in addition to γ-radiation.

A similar celluloid box also containing 100 weevils s kept near by, shielded from radiation, to serve a control.

At the beginning of the exposure the weevils were wling slowly around the bottom of the box in eir usual fashion. Under the action of the radiation ey began to move faster, and towards the end the exposure, which lasted one hour, they owed a very lively motion. This increased activity s not due to local heating, for a thermometer ced over the radium tubes showed no significant e of temperature

After exposure, all the insects were alive and had umed their normal rate of movement. They were nsferred to a jar of grain and incubated at a nstant temperature of 27° C. The controls were ated similarly.

At first, it seemed as if the radiation had produced effect, for living insects were observed from time time in the jar containing the exposed culture. ter an interval of two months, however, both jars re carefully examined. It was found that the posed culture contained no living insects, whereas e control culture was flourishing. Thus it appeared t exposure to radiation had sterilized the weevils d prevented them breeding.

Unfortunately it was not possible to get a measure the radiation dose, as the radium had to be put derground soon after the outbreak of war, as a precaution against air attack. The γ-ray dose at the centre of the celluloid box may, however, be roughly estimated at 35,000 röntgens per hour. To this must be added the contribution of the β-radiation; this cannot be reckoned with any degree of accuracy owing to the complexity and uncertainty of the screening corrections. Nevertheless, it seems likely that the total dose delivered in one hour by β- and γ-rays together was of the order of 10^5 röntgens.

To deliver a dose of this magnitude to a fast-moving stream of grain entering a silo bin would not seem a practical procedure at the moment, but the development of X-ray plants of large radiation output may some day make this feasible. It should be remembered also that sterilization of insects may be possible with smaller doses of radiation than were given in this particular experiment.

However this may be, we feel that the principle involved is of sufficient interest to warrant a fuller investigation, which we hope to carry out when circumstances permit.

We gratefully acknowledge the loan of 8 gm. of radium by the Union Minière du Haut Katanga.

Local Growths in Animals Produced by Injection of Intercellular Wound Hormones

THE following preliminary experiments show that intercellular wound hormones[1], produced by living cells as a physiological response to injury[2], induce local overgrowths when injected repeatedly into rats and mice.

The wound hormones were prepared by mincing whole rat or mouse embryos, or adult rat spleens, washing the minced tissues and suspending them in isotonic salt solution, irradiating the cell suspensions with lethal ultra-violet, and obtaining the intercellular fluids (containing the wound hormones) free from cells by centrifugation and Berkefeld filtration. Control fluids were obtained from tissues treated similarly except that irradiation was omitted. All manipulations were carried out aseptically and (prior to centrifugation) at body temperature. The details of the technique have been reported elsewhere[3].

The fluids were injected subcutaneously over the abdomen in 0·5 c.c. quantities. In the first two series of experiments (using white mice) injections were made thrice weekly; in the third series (using white rats) they were made twice weekly. Six to eight weeks after starting injections, all animals in the test groups of all series developed hard, tumour-like masses near the site of injection, or, in some instances, on the tails or feet. These continued to persist, and usually to grow in size, until the animals were killed at the end of ten to twelve weeks. A typical tumour removed at autopsy weighed 1·15 gm. Histological examination of the overgrowths showed them to be composed largely of connective tissue and striated muscle.

Control fluids led in some cases to the development of similar but much smaller and less persistent growths. In this connexion, it must be remembered that some wound-hormone production would be expected in the control preparations because of unavoidable mechanical injury to the tissues, since it has been demonstrated that mechanical injury leads to the production of such factors[4].

The work is being extended with more highly purified preparations, and will be described in detail when the current investigations are completed.

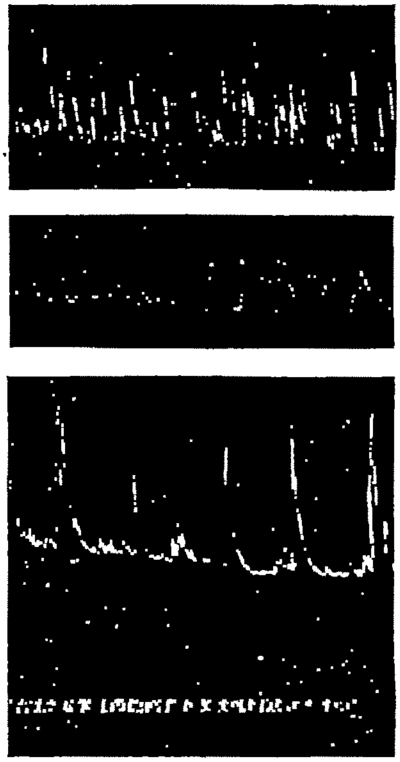
Intermittent Activity in Polychaete Worms

THE undulatory movements by means of which Nereis renews the water in its burrow are well known. Lindroth[1], in a recent study of respiration in *N. virens*, finds that the movements are intermittent in this species. "Ventilationsperioden von etwa 5 Minuten Länge werden von Ruheperioden von 20 bis 30 Minuten abgelöst". He quotes instances of other polychaetes, in which ventilation periods alternate with rest periods.

Lindroth explains this intermittent activity as follows. When the worm is quiet, the contents of the burrow can be regarded as a closed system. Owing to the metabolism of the worm, oxygen gradually disappears and other substances accumulate. Finally, an unspecified chemical factor acts as a stimulus and evokes the respiratory waves. The resulting renewal of the water in the burrow soon removes the stimulus, so the movements cease again.

It would, however, be unwise to adopt this simple and attractive hypothesis unless the actual chemical stimulus can be experimentally identified and demonstrated. Intermittent rhythmic activity is very commonly shown by isolated nerve-muscle preparations of polychaete worms and it often seems to be the normal activity pattern. I found[2] that *Arenicola marina* shows rhythmic outbursts of gulping or feeding movements alternating with periods of quiescence, and was able, by studying a series of dissected pr parations, to localize the pace-maker for this inte mittent activity in the walls of the œsophagu Wu found[3] that longitudinal ventral strips of tl body wall of the same species (including the ner cord) "often showed outbursts of rhythmic activi alternating with more quiet periods". I observe similar activity outbursts (although in this case on exceptionally) in dissected preparations of Glycer Miss I. C. Ledingham and I have just complet a study of the action of low salinities on isolat rhythmic preparations from polychaete worms. Th involved taking kymograph records of great numbe of longitudinal ventral body wall strips (includi the nerve cord) and of 'isolated extroverts' (that the proboscis and part of the œsophagus, with t stomatogastric nervous system but without t circum-oral nerve ring or brain) from *Nereis diver color* and *Perinereis cultrifera*. We find that regular intermittent activity very commonly appea especially in preparations from the latter speci in which it seems to be the normal pattern.



The accompanying records, taken by Miss Ledin ham and me, show two body wall strips (abo and an extrovert (below) from *Perinereis cultrifera* all from different individuals. The preparations we suspended in a large volume of sea water, well aerat at 16°–19° C., and the movements were recorded l light isotonic levers. The time signal marks minut The occurrence of periodic 'activity outbursts', both parts of the nervous system, is obvious. Son times the body wall strips give records like that the extrovert in the figure, that is, short, vigoro outbursts at long intervals.

Except in the case of the *Arenicola marina* extr vert, where the intermittent rhythm is very stea and regular and its normality can scarcely be doubt contractions of these isolated preparations have to be interpreted in terms of movements of the ole animal. The frequent occurrence of inter- tent activity in body wall strips suggests, how- r, that the periodic ventilation of Nereis may ult from the inherent nature of its nervous chanism, and not from the alternating accumula- and removal (by the ventilation movements mselves) of metabolites.

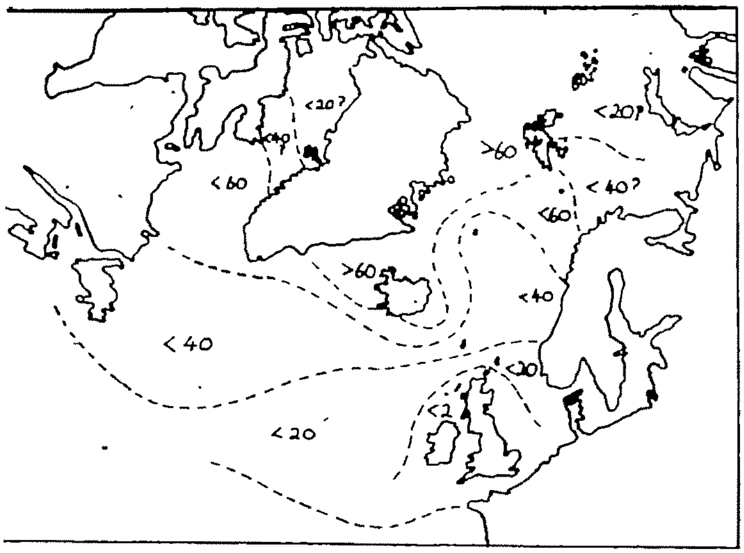
tribution of the Colour Phases of the Fulmar (*Fulmarus glacialis*)

HARACTER gradients[1] in animals are receiving so ch attention that additional raw material, par- ularly of a quantitative kind, is urgently required.



ERCENTAGES OF 'DARK' FULMARS IN THE NORTH ATLANTIC (SUMMER BREEDING AND OCEANIC DISTRIBUTION).

ornithologists, who by reason of their numbers e already made a good start with the distribution he 'bridled' form of the guillemot (*Uria aalge*)[2,3], ht now well extend their observations to the mar (*Fulmarus g. glacialis*). Unlike the guillemot, fulmar does not exhibit a simple 'dimorph-ratio e', but shows a polymorphic one (first discussed Eagle Clarke[4]), which seems, from the limited lence available, to be of a rather complicated ure. The accompanying distribution map, com- d from twenty-six literature sources, gives a eral indication of the situation.

very stage between almost white and dark 'blue' nage is found in the fulmar. The darkest specimen mined (from Bear Is.)[5] seems to be Ridgway's[6] *tura drab* (pl. xlvi) on the back, and on the breast between *mouse-grey* and *deep mouse-grey* (pl. li), a plumage very similar to that of the dark form of the North Pacific subspecies, *F. g. rodgersii* (a race in which a similar polymorphism appears to exist).

To prepare the map, birds have been held to be 'dark' or 'light' according to which side they fall of the arbitrary mean suggested by Roberts[7]. I have attempted to interpret the literature in terms of this mean.

The maximal preponderance of dark forms seems to extend from Iceland seas (excluding, apparently, the Iceland breeding stock) via east Greenland to west Spitsbergen. Towards Bear Island, there is a slight diminution in the proportion, and the Jan Mayen birds appear to be predominantly of the lighter forms, as are those of the Faeroes, which were only colonized between 1816 and 1839. In Britain dark forms are extremely rare (only, it seems, about 2 per cent); with the exception of the large colony on St. Kilda (*circa* 20,000 pairs), the rest of the British population (*circa* 40,000 pairs) has established itself since 1878.

The situation east of Spitsbergen is obscure, but it is probable that the gradient falls somewhat sharply in that direction. The birds' distribution extends eastwards as far as Lonely Island (Einsamkeit).

From the West Atlantic information is also scanty, but the numbers of the dark forms seem to reach a peak of 40-60 per cent in the south of Davis Strait and may fall off northwards towards Baffin Bay, and southwards towards the Newfoundland Banks.

Examination of skins, and observation in the field, indicate that the polymorphic forms, though exhibiting every gradation, can be arbitrarily grouped in four main classes:

DD (double dark). Underparts uniform very dark or dark blue-grey, head and neck dark.

D (dark). Underparts uniform medium or light blue-grey, head and neck dark.

L (light). Underparts white, near-white, or white flecked or shaded with grey; on crown, nape and hind-neck grey colour continuous with that of mantle.

LL (double light). Underparts white, or near-white, head and neck white.

Roberts's arbitrary mean lies between *D* and *L*.

I shall be very glad to receive any counts of the relative numbers of these forms, either at colonies or on sea-transects. In the latter case it will be useful to give at least the noon positions of any voyaging ship from which a series of observations is taken.

Rules of Zoological Nomenclature

SUCH cases of the abuse of the rules of zoological nomenclature as are indicated by Prof. W. Garstang in NATURE of September 9 indicate a failure in the functioning of the present rules which is an ever present danger and hindrance to the work for which systematic researches exist. The existing rule that no names shall be changed if the result will be greater confusion than uniformity needs enforcement. At present, this can only be done by a long and cumbrous procedure which has resulted in comparatively few, a few hundred, *nomina conservanda*, and those generally only of common genera, and very few species. It is also unfortunate that this remedy comes after the damage has been done. The position needs something much more rapid and thorough which, under the present scheme, would mean the appointment of whole-time searchers in each group, who would present lists of a thousand or so names annually to a committee of superhuman patience. Such a scheme is utterly impossible.

Are there any alternatives? I suggest that the old rules, having served well in the old days, should now be altered radically. Consider how different is our position now. We have a vast body of systematic literature, upon much of which the most careful labour of the most skilled observers has been freely and generously expended. This vast labour has not been, for the most part, an end in itself; its essential value is to be the foundation of such subjects as ecology and genetics. It must therefore be regarded as an essential tool, to be altered and adjusted only when we are compelled by dire necessity. What would become of a factory in which the machinery might be adjusted without reference to the work of the factory as a whole? This is exactly the danger the framers of the rules of nomenclature had in mind and tried to avoid, but which insistence on the letter of the law, and neglect of its spirit, has made rampant.

I venture, therefore, to recall a suggestion I made more than thirty years ago, which was approved by the late Sir Arthur Shipley and published in NATURE, namely, that a small committee of experts in each group should select the most useful books in each, the names in which should be unalterable for any literary or priority reasons. Conversation with my friends shows that I must enlarge a little; it seems to be taken that I mean the establishment of a kind of Holy Writ—an idea abhorrent to science. The committee on group *Z*, say, decides that the most useful books in that group are *A* . . . *H*, dated, say, 1850 to 1920 (for obvious reasons no book of very recent date could be included). It is then found that the author of book *E* published excellent descriptions of a number of species, but took little trouble over synonymy, and some of his species are the same, or, in the opinion of subsequent authors, should be reckoned as varieties of species described by the authors of *A*, *B* or *C*. The names used by the latter authors therefore have priority, and are to be used; research into literature, once important and useful, but now only of historic value, of older date than that of the book *A*, will not be allowed to upset *E*'s names. Criticism founded on new knowledge, or even individual views of the relationship of species and genera, would be as free as they are now. In this way thousands of names, species as well as generic, could be saved by one year's work.

Something might also be done by ignoring the so-called work of those who change names on trivial grounds, as sinners against the workers for wh
convenience they, in fact, exist. The first neces
is that a worker who is not a specialist in systema
shall be able to get the description, variation
distribution of the species with which he is dea
with the least possible difficulty and the grea
possible certainty. Again I repeat, this is the
for which systematists work, and those who wo
put difficulties and delays in the way should rec
every possible discouragement from all scien
workers.

Birds of Britain

IN the review of the "Handbook of British Bir
vol. 3, in NATURE of October 21, p. 691, there
some criticisms which require an answer. Some
merely matters of personal experience. 'S. G.'
never seen bracken used for nesting by the gol
eagle, but others have. Nests in trees have alw
been a small minority, except in one restri
district. As to the share of the sexes in provi
food for the young, H. B. Macpherson, who watc
a nest for long periods in 1909, records in his di
no fewer than twenty occasions on which the fem
brought food to the nest. A. Brook in his diary st
that the hen brought a grouse and a young har
the nest on June 14. While I agree, and h
stated in the "Handbook", that the male takes
chief part in this work, it is impossible to ig
Macpherson's evidence, and 'S. G.', to whom I m
tioned this fact, could give no explanation of
discrepancy.

May I quote one sentence from 'S. G.'s' own not
"I believe that the cock [*sic*] must have come tw
to the eyrie unperceived by me, for when I left
hide there were two more grouse in the nest."
eyrie in question was ten yards from where 'S.
kept watch.

F. C. R. JOURDAI

Whitekirk,

Synthesis of Coenzymes I and II

URING the past year, two biological methods for determination of coenzymes I and II in blood e been reported[1,2]. Kohn and Klein, using the hod described by Kohn, have reported recently *in vitro* synthesis of the pyridine coenzymes I . II by human erythrocytes[3]. In their study, sh defibrinated blood was incubated in tightly pered flasks, or tubes, for 18–24 hours at 29°–35°'' ; arently a mixture of red cells, white cells and serum used. In the presence of added nicotinic acid de or nicotinic acid, the *in vitro* synthesis of these zymes by defibrinated blood had also been erved in this laboratory, but from our experi-its it seemed that the red cells stored and carried enzymes instead of performing the synthesis. ordingly, we took duplicate samples of venous od from five normal persons, two patients with elogenous leukæmia, and one patient with phatic leukæmia, and by repeated washing arated the red blood cells, the white blood cells the serum. In each case, 1 c.c. of venous blood, its hæmatocrit equivalent of washed cells, was ubated 18 hours with an equal volume of saline ch contained 0·25 mgm. of nicotinic acid amide cubic centimetre. The control tubes contained nicotinic acid amide and were incubated the same gth of time with an equal volume of saline.

epeated tests show that : (1) the concentration oenzymes I and II in normal human blood and æmic blood is doubled after incubation with otinic acid amide ; (2) carefully washed erythro-es, however, from normal blood and leukæmic od, resuspended in saline or serum, show no ease in the concentration of coenzymes I and II r incubation under similar conditions ; (3) the centration of coenzymes I and II is greatly eased in a suspension of white cells of the lymphoid . myeloid series after incubation with nicotinic l amide.

he above findings are inconsistent with the state-nt of Kohn and Klein that the normal erythrocytes omplish the synthesis of coenzymes I and II after ubation with nicotinic acid, and suggest the tenta- hypothesis that nucleated cells are essential for synthesis of these complex enzymes.

Benzedrine and Brain Metabolism

HE unquestioned value of benzedrine (phenyl-ropylamine) in the treatment of narcolepsy has le it of interest to discover in what ways this g might influence metabolic events in the nervous em.

It has been known for some time[1] that the presence of amines such as tyramine or isoamylamine brings about a marked diminution in the respiration of brain examined *in vitro*. In spite of the fall, however, of the oxygen uptake of brain tissue respiring at 37° in a glucose phosphate medium, oxidation of the amine[2] may take place with the formation of ammonia and the corresponding aldehyde[3]. The enzyme responsible for the oxidation of the amine has been termed amine oxidase, and it has been proved[3] that certain amines which are but feebly or not attacked by the oxidase nevertheless combine with the enzyme and compete with amines which are vigorously oxidized. Among such amines[4] is benzedrine which, whilst suffering little or no oxidation by the amine oxidase of brain, greatly inhibits the oxidation of tyramine or isoamylamine in the central nervous system.

It has now been found that the fall in brain respiration brought about by the presence of tyramine or isoamylamine can be partially or wholly relieved by the addition to the system of small quantities of benzedrine. This phenomenon is shown by the results given in the following table. The effect of adding benzedrine to brain tissue consuming oxygen in the presence of glucose and of tyramine is greatly to stimulate the oxygen uptake.

OXYGEN UPTAKE AT 37° OF GUINEA PIG BRAIN TISSUE IN PRESENCE OF GLUCOSE-PHOSPHATE AFTER 2 HOURS EXPOSURE TO BENZEDRINE, TYRAMINE AND A MIXTURE OF BENZEDRINE AND TYRAMINE.

Amine present	μl O_2 uptake in 1 hour	
	Expt. A.	Expt. B.
Benzedrine sulphate (0 03%)	193·6	177 7
Tyramine (0·03%)	71·1	90 1
Tyramine (0·03%) + Benzedrine sulphate (0·03%)	198 5	170·8

The facts show that the diminution of brain respiration brought about by the amine $R.CH_2NH_2$ when present at low concentrations is not due, or wholly due, to the presence of the free amine but to the accumulation of the aldehyde R.CHO formed as a result of oxidation of the amine by the amine oxidase. Benzedrine owes its stimulating effect on brain tissue respiration in the presence of $R.CH_2NH_2$ to its inhibitive action on the formation of R.CHO. Owing to the competition between benzedrine and $R.CH_2NH_2$ for amine oxidase, the greater the quantity of the inhibitory amine present the greater is the quantity of benzedrine required to neutralize the inhibition of brain respiration.

The molecule R.CHO, for example, isovaleric aldehyde, has been found to be highly toxic to respiratory processes in brain, and this toxicity is not influenced by the presence of benzedrine.

Benzedrine at low concentrations, for example, 0·001 per cent, has little influence on the oxygen uptake of brain when this respires in a glucose medium in the absence of an inhibitive amine ; its stimulating effect is only observable if an amine such as tyramine is also present. At relatively high concentrations benzedrine itself exerts large inhibitive effects on brain respiration. Such effects are due to causes other than aldehyde formation.

Benzedrine does not neutralize the inhibitive action on brain respiration of narcotics such as the barbiturates, or of a drug such as bulbocapnine. Its effect appears to be confined to the amines capable of aldehyde formation in the central nervous system.

It is permissible to suggest, in view of these facts, that the clinical effects of benzedrine administration may be related to respiratory changes in the brain. It would be of interest to discover whether there accumulates in conditions of narcolepsy toxic bodies (? aldehydes) the formation of which is retarded by the administration of benzedrine

Details of the experimental results recorded above will be published shortly.

Factors Determining Physical Size and Proportions

THE mathematical methods[1] devised to deal with the analysis and distribution of human ability and temperament[2] can be fruitfully applied to problems of isometric and allometric growth[3] and to those of physical anthropology[4].

A factorial analysis was undertaken of fourteen anthropometric measurements obtained from two separate adult male samples, one consisting of 64 mental patients heterogeneous for age and disease, and the other of 50 university students homogeneous for age and social status. The two independent analyses gave strikingly similar results.

Without identifying statistical entities with biological principles, it was shown that physique, in general, could be most usefully regarded as the resultant of two relatively independent factors or sets of processes, one determining the growth (or size) of the body as a whole in its various dimensions, and the other determining disproportionate development in length or circumference of the body. The establishment of racial or constitutional (growth) types would have to be based on a study of these two factors separately. These factors may ultimately be explicable in metabolic and genetic terms. The conventional indexes of somatometry would, if this view be correct, give little hope of revealing true racial or growth type differences, since 'type', as defined by excessive linear or circumferential development, is masked by the general processes governing size, and this latter factor would have to be statistically controlled if 'type' is to become evident.

As regards the problem of physique and nutrition, the implication seems to be that two norms would be required: a norm for general or uniform development of the body, and another for typological variations.

Three measurements of the head, four of body length (arm, leg, trunk, stature), three of body breadth (shoulder, chest, pelvis), three of body circumference (chest, waist, pelvis) and one sagittal (chest depth) were used. Coefficients of variation for the measurements descended in this order of magnitude: circumferential, sagittal, breadth, length, head. Of all the fourteen measurements, breadth and circumference of the pelvis and waist circumference were found most informative (that is, most discriminative) of general size or growth, and leg length together with circumference of waist and pelvis m informative of typological characteristics when size influences are statistically controlled.

Surface Features of Mars at the Recent Oppositio

ADVANTAGE has been taken of the recent v favourable opposition of Mars to make a cl examination of the surface features. The 9 in. Co photo-visual refractor has been employed, usu with a magnification of 250. A fortnight of reasona clear weather at the end of July assisted considera and nearly one hundred drawings of the disk h been made. The following is a summary of the c points of interest revealed by these:

(1) Vast changes appear to have occurred on north-east edge of Mare Cimmerium, where apparently new dark marking has appeared. T seems to occupy the region of Cyclops and Cerbe II, Pambotis Lacus having apparently beco merged in it. It is separated from the main M Cimmerium by a narrow isthmus, broader at north end and very prominent under certain illumi tions. At the end of July it was very plain a obvious, being one of the darkest markings on planet. The reduction of the numerous drawings it has yet to be made, so that exact positions are available at present.

(2) Until July 22, Hellas was bright and obvi with a sharply defined margin, particularly on west, but on July 23 it has become dark and h with a much less definite outline. It remained so every subsequent observation. At all times, e before July 23, it was darker than the remainder

(3) Edom Promontorium became very pl towards the end of August and was one of the m prominent features. Earlier, a white region Ausonia showed up very plainly.

(4) Iuventæ Fons showed as a dark point July 10 but was not seen again, despite a cl search for it.

(5) The North Polar region was a very interesti feature. Apparently it was covered by a v eccentrically situated cap of fog or ice. At tin this was invisible but on other occasions it extenc well on to the disk. Probably this can be accoun for by the rotation of the planet, although t point has not yet been investigated. Generally was duller than the South Polar Cap, but on July it was equal to it in brightness, while on August 4 quite outshone everything on the disk, the Sou Polar Cap appearing very dull in comparison.

Various other features of interest have been not particularly in the Solis Lacus region, but, until final reduction of the observations is complete, it impossible to discuss them fully. It is hoped publish the entire results in due course.

Measurements of the Velocity of Light

M. E. J. GHEURY DE BRAY suggests[1] that measure-ents of the velocity of light show that it is changing cording to a formula:

$$c = 299{,}900 - 3{\cdot}855\,T, \tag{1}$$

being measured in years from 1900.

Assuming that Planck's constant and the energy E ven out by an excited atom remain unchanged, the lation

$$E\lambda = ch \tag{2}$$

ows that a change in c must be accompanied by a oportional change in λ. But the wave-length of e red calcium line has remained constant to within e part in five million for thirty years, only 0·5 per nt of the change required by (1).

It is probable that there are unsuspected systemic errors in the determinations of c.

KITCHENER.

Trinity College,
Cambridge.

---

[1] ATURE, 144, 285 (1939).

THE decrease of velocity of light deduced from the d-shifts is of the order of 1 km./sec. in 6,000 years, 1 in 600,000,000 for thirty years, which is quite nsistent with the apparent constancy of the wave-ngth mentioned by Lord Kitchener. Our observa-ons, being affected by unsuspected systematic rors, and covering only a third of a century, give what is probably a greatly exaggerated rate of slowing down. The remarkable fact is that *all* the determinations are unanimous in indicating the existence of such a variation, and the red-shifts, if interpreted so as to escape from fantastic results, confirm it.

The Table 1 of the communication referred to cannot be dismissed on the ground of "unsuspected systematic errors". It is admitted that the method of the revolving mirror may suffer from physical bias, but no such reproach can be levelled against the toothed wheel method, which is only open to objections of a physiological nature. These can be readily overcome by substituting for the observer's eye a photo-electric sensitive device. While France and the United States share between them practically the whole initiative in the measurement of c, Great Britain has only to her credit a conspicuous failure. Is there in this country no one who can redeem it from this position and settle this question, which lies at the basis of physical science, considered in its broadest aspect?

Two observations, of Newcomb (1882·7: 299860) and of Michelson (1882·8: 299853) agree so closely that, if we consider that they were made by different observers, working independently with different instruments and different techniques, in different places, they must be extremely accurate, despite their large probable errors. It is significant that the second in date gives a lesser value of c.

M. E. J. GHEURY DE BRAY.

49, Great Thrift,
Petts Wood.
Nov. 2.

Points from Foregoing Letters

L. G. Grimmett and G. V. B. Herford describe an periment to test the possibility of controlling insect sts by means of radiation, in which it appeared at grain weevils (*Calandra granaria*) were sterilized a radiation dose of β- and γ-rays estimated at ^{5} rontgens.

Injection into rats and mice of intercellular wound rmones, produced by injuring tissue cells with thal ultra-violet, was found to produce local over-owths, in investigations of J. R. Loofbourow, A. A. ieto, D. Whalen and Sister M. M. Lane. The tumours re composed mainly of connective tissue and iated muscle.

G. P. Wells discusses the frequent occurrence of termittent rhythmic activity in isolated prepara-ons from polychaete worms.

J. Fisher describes the distribution of the colour-ases of ***Fulmarus glacialis***, and shows the existence a polymorph-ratio cline. The dark types are most merous in the neighbourhood of south and east eenland and west Spitsbergen, and fall off in oportion northwards towards Baffin Bay, and uthwards towards the Newfoundland Banks and e British Isles; in the latter they constitute less an 2 per cent of the population.

C. Crossland expresses dissatisfaction with the rking of the rules for zoological nomenclature, on e grounds that the present methods of making ***mina conservanda*** are too cumbrous, and he pro-ses an alternative method. He points out that the rk of the systematist is not an end in itself, but exists that workers in such subjects as ecology and genetics may, with rapidity and certainty, find out what is known of the species' structure, relationships, distribution and ecology; any interference with the literature which hinders this end should be discouraged.

P. J. G. Mann and J. H. Quastel show that benzedrine stimulates the oxygen uptake of brain *in vitro*, when this respires in the presence of certain amines. This is accomplished by an inhibition of the formation in brain of toxic aldehydes.

An investigation is reported by J. I. Cohen in which factorial methods of analysis, as used in psychometry, are applied to anthropometric measurements. The results suggest that physique may be regarded as determined by two sets of processes, one governing growth (or size) in all body dimensions and the other, relatively independent of the first, governing specifically linear or circumferential development.

Lord Kitchener shows that, with certain assumptions, a large secular change in c is inconsistent with the observed constancy of spectral wave-lengths. M. E. J. Gheury de Bray points out in reply that the decrease of velocity of light deduced from the red-shifts is 1 in 600,000,000 for thirty years, which is not inconsistent with the apparent constancy of the red calcium line. It is suggested that the toothed-wheel method in combination with a photo-electric sensitive device should be used to re-determine the velocity of light.

RESEARCH ITEMS

Prehistoric Rock Pictures in Dutch New Guinea

ROCK PAINTINGS collected in the islands off the coast of the Onia Peninsula, Dutch New Guinea, by members of the Frobenius Expedition in 1932 have been described and figured by J. Röder (*Man*, Nov. 1939). The paintings—there are no engravings—have been executed in grooves and hollows of the cliffs, washed out by sea-spray, which form a series of galleries, following the coast-line at a height of two to four metres above high-water mark. Apart from quite recent drawings, three layers can be distinguished. For the most ancient, red paint is used. In this layer four styles can be recognized, though there is a far-reaching uniformity of subject. In the earliest style, however, the most characteristic subject is the silhouette of the hand, with silhouettes of feet and arms. The hands occur in dozens on the same wall—right hands, left hands, hands of children, but only rarely with mutilated fingers. In aboriginal tradition these mark the wanderings of the ancestral immigrants, who were blind. In later styles of the red paint layer, the hands are absent, but other subjects are much the same—fish, trepang, crocodile, lizards, and man, at times scarcely to be distinguished from an animal. Often, apart from the big find spots, the human figures are surmounted by a large head-dress like a pointed nightcap, the hands being raised as in adoration. These are now said to be representations of ancestors. The sex is prominently characterized; and sometimes the figure is so abbreviated that only the sign of sex remains. Here is evidently a fertility cult, which survives to-day in the use of wooden figures. Subjects in black paint point to a different culture in which the boat is prominent—previously unrepresented, but now taking a part in cult. There is in this layer a progressive degeneration in style and execution. Paintings in white are mostly superimposed on the red, as if a comment were intended. Caves with pictures of both the red and black periods are found. A cave deposit on excavation revealed three cultural layers, of which two contained pottery, but the lowest flint implements only. A figure on a stalactite pillar with arms upraised was evidently an ancestral figure or deity to which, presumably, offerings had been made on a stone showing traces of red from the second cultural layer. Burials in the semi-caves were made up to represent boats.

Basque Origins

THE results of recent research on the origins and affinities of the Basques, which had been interrupted by the Civil War, are reviewed by Mr. Rodney Gallop in the course of an account of the people appearing in *Discovery* of October. The most recent researches tend to confirm the 'positivist' view of Julien Vinson that "from the earliest times the Basques have never been more than a small tribe dwelling in a few valleys of the Western Pyrenees". The basis of the confirmation is archæological and anthropological rather than linguistic, and rests on the existence of a uniform culture in north-west Spain and south-west France from palæolithic times onward, belonging to a people whose skulls, found on both palæolithic and neolithic sites, correspond closely with a type which predominates among the Basques of to-day, but is found but rarely amo the adjacent French and Spanish populations. Th type lies between the brachycephalic and dolich cephalic, and is distinguished by prominent templ high cheek-bones, a narrow loose jaw, a long point nose, and a projecting chin. The affinities betwe the Basque and Iberian languages, demonstrated place-names and fragmentary inscriptions fou almost all over Spain, are possibly to be explained due to adoption or free borrowing by the primiti Pyrenean ancestors of the Basques on first conta with the relatively advanced Iberians. Antiquity stamped on Basque syntax and vocabulary, the latt pointing to a derivation from an age of stone and time reckoning of a three-day week. Caution necessary in cultural analysis; and although it true that the Basque cultural heritage is distin from that of their neighbours, a careful comparati study of Basque traditional peasant art reve numerous analogies with the common stock European tradition.

Nitrogenous Excretion from Root Nodules

FOLLOWING the experiments of A. Virtanen Helsinki, G. Bond and J. Boyes have investigat the possible excretion of nitrogenous substances fro the root nodules of the leguminous plants, soya bea garden pea and broad bean (*Ann. Bot.*, N.S., 3, N 12, 901; 1939). Three different grades of sand we used, and in some cases, soil. In spite of Virtane claim that extensive excretion was frequent obtained, these authors obtained consistently neg tive results from their experiments similarly carri out with sand cultures. The soil cultures we inconclusive. The discrepancy may be explained the presence of considerably more direct sunlight Helsinki than at Glasgow; but this has yet to established.

Polyploid Cells in *Cucumis Melo*

C. D. ERVIN (*Proc. Nat. Acad. Sci.*, 25, 335–33 1939) shows that the production of tetraploid cells the periblem of roots is a common and freque occurrence. Rarely is the plerome affected, a octoploid cells are infrequent. The number of tetr ploid cells increases towards the older portions of t root. Secondary pairing of chromosomes is oft evident in tetraploid cells.

Coasts of Cardigan Bay

IN a study of the present-day coastal forms Cardigan Bay ("Sand and Shingle Formation Cardigan Bay", *Geog. J.*, Sept. 1939), Mr. J. A. Stee dealing particularly with the shore between Pwllh and Fairbourne, shows that there is a steady moveme of beach material towards Tremadoc Bay. Along t Lleyn coast this material moves eastward, and alo the Merioneth coast in the main northward. Bo movements are the result of prevailing south-wester winds which cause the waves to strike at an obliq angle and so move the material. Material broug down by the rivers Glaslyn and Dwyryd has help to shallow Tremadoc Bay. The north-eastern entrant shows great sand-flats produced by t beach drift. This accumulation has caused the wav break on a constantly shallowing bottom, pro- essively farther and farther from the mainland. nsequently Morfa-Harlech and Morfa-bychan have wn seaward with their outer beaches at right gles to the main direction of wave approach. tween them the rivers have maintained an open nnel. These processes are still continuing.

mage by Spray Fluid

IT is most important that a spray fluid applied for control of insect or fungal attack shall not pro- ce any injury of the host plant. This is unfor- nately the case with many Cucurbitaceous crops America, which cannot be sprayed with Bordeaux xture without considerable stunting and loss of ld. James G. Horsfall, G. E. R. Hervey d R. F. Suit have investigated this damage (*J. ric. Res.*, 12, 911–928, June 1939) and find t it is at a minimum when the spray fluid is tral. Changes in the hydrogen ion concentration her towards alkalinity or towards acidity bring out dwarfing and leaf deformation, for both the per factor and the lime in the mixture play their rt in producing damage. Reduced photosynthesis, hardening of young cells by the calcium ion, and ysiological drought of the tissues when Bordeaux xture is present, appear to be the main causes of ury. The obvious remedy, namely the use of tral spray fluid, is not regarded as practicable der agricultural conditions, but further research uld ultimately indicate the appropriate practice.

in the Netherlands

IN *Mededeelingen en Verhandelingen*, 42 (Kon. d. Met. Inst.), Dr. C. Braak discusses the occurrence fog in the Netherlands, as revealed by observations de at eighty-two observing stations well distributed r that country. On the basis of Hann's classifica- n, according to which a place with less than 25 days per annum is not a foggy place but one with re than 50 fog days can be regarded as foggy, the therlands occupies an intermediate place only, ich fact will perhaps come as a surprise to many, low-lying country with so many dykes and such indented coast-line, and one containing extensive nufacturing districts, might have been expected be conspicuously foggy. Dr. Braak offers no ex- nation, and one can only suppose that the gener- open character of the country allows the wind circulate very freely—the presence of so many dmills is suggestive of this being the case—and t this generally prevents the air from becoming gnant enough for fog to form. The annual number fog hours deduced by Köppen's method is 442 at sterdam (Filiaal) but only 157 at Amsterdam rtus). In general, the figure lies between 200 and , at lightships as well as on land. Of particular erest are four charts, Figs. 3–6, showing the per- tage of the year's fog days that occurs in each son. It might have been expected that these uld show broadly a tendency for fog to be most quent in winter at places farthest from the sea, ich would most often be under the influence of tinental anticyclones, while the coastal towns and tships would have most of their fogs in the early t of the summer. This is definitely not the case. would be more accurate to say that in general ter (December–February) is the time for fog, even the lightships, and that in the north-west more n half the year's fogs occur in the winter quarter. There is a general falling off in fog frequency in the spring (March–May) quarter, and over a large proportion of the country the months June to August yield less than 5 per cent of the year's total, 10 per cent being exceeded only at lightships. It is only in autumn that distance from the sea and fog frequency show a marked tendency to be associated. It must be remembered, however, that on the Continent the available water vapour is reduced by frost in winter more often than in the British Isles, and this reduces the number of fogs in the coldest part of the winter and tends to make the annual maximum frequency fall earlier than in the latter.

Reaction of Fluorine with Carbon

MOISSON in 1890 obtained carbon tetrafluoride, CF_4, by the action of fluorine on carbon, and Ruff and Keim (1930) showed that hexafluoroethane, C_2F_6, and possibly higher compounds were also formed. J. H. Simons and L. P. Block (*J. Amer. Chem. Soc.*, 61, 2962; 1939) have further investigated the reaction, which is complicated by explosions unless the reaction tube is heated just below dull red, and the carbon is mixed with amalgamated copper gauze or with a small quantity of mercurous or mercuric chloride. The liquid product was fractionated, and the following compounds isolated: CF_4, C_2F_6, C_3F_8, C_4F_{10} (two isomers), C_5F_{12}, C_6F_{12} and C_7F_{14}. The first five are gases, the rest liquids. The probable synthesis of a large number of similar compounds is inferred. Their physical properties approach very closely those of the inert gases.

Nature of Radio Fade-out

A PAPER (*Phys. Rev.*, March 15) by L. V. Berkner discusses the nature of radio fade-outs in the earth's sunlit hemisphere which are coincident with bright solar chromospheric eruptions and with certain geomagnetic effects of a specific character described by Fleming and McNish. They are examined by means of the vertical incidence recording of ionospheric echoes with a wide range multi-frequency technique. It is concluded by examining a series of observations that a fade-out is best described as an upward projection of the lower (absorption) limit of echo return, and that it is caused by intense absorption of ionizing radiation which emanates from bright chromospheric eruptions either at the base, or below, the *E* region, that is, below the 110 km. level. It is shown that no appreciable absorption of chromospheric-eruption radiation takes place at a height greater than that of the *E* region. Hence a process of selective absorption must operate. The localization of the region of intense absorption to space below the 110-km. layer, is interesting. An analysis of geomagnetic effect during a number of fade-outs observed by McNish shows it to be an augmentation of the diurnal variation of terrestrial magnetism. This is proved by the fact that not only is the magnetic vector of the associated geomagnetic effect always in the same direction as the diurnal variation, but also these vectors agree in direction at locations where the diurnal variation vector appears anomalous. It is not only similar in character to the diurnal variation but must also arise in the same atmospheric regions, and, therefore, must in fact be a part of it. It appears from the state of the theories that only the Stewart-Schuster 'atmospheric dynamo' theory of diurnal variation is possible, taking into account the restrictions imposed by these observations.

EUROPEAN ORDER AND WORLD ORDER

POLITICAL and Economic Planning (P.E.P.) has issued a readable but comprehensive pamphlet entitled "European Order and World Order". The principles on which the maintenance of Western civilization depends are summarized under four headings: freedom of thought, speech and movement; establishment of the rule of law both nationally and internationally; the progressive use of the State as an instrument of public welfare, not merely for policing or the protection of private interests; and the organization of production and distribution to raise the standards of living and of life of all peoples. Compromise on, or surrender of, any of these essential values endangers the stability of our whole civilization. The central problem for Europeans is to make clear those principles, to see that our institutions and policies conform to them and to place behind them an overwhelming and enduring assembly of forces.

The success of the totalitarian challenge has been due largely to lack of clear thinking and moral courage in the democracies. It has scarcely been recognized that peaceful change, in both domestic and international affairs, depends upon extensive research and planning, so that problems are seen and dealt with before they become chronic or acute, and before their reactions on other problems multiply. Technical and economic advances have made all countries so closely interdependent that the corresponding political advances can no longer be delayed.

While a crushing military defeat of Germany may not be necessary, it is vital that the basic principles of civilization represented by Great Britain and France should emerge triumphant. It has been necessary to reassert those principles in war because of recent failures to vindicate them in peace—failures which arose inevitably from the widespread attitude which insists on a complete divorce between economics and social needs, and at the same time has refused to face continuing after school age that blend of training and public propaganda known as education.

The fundamental task in reconstruction is to fill in these gaps in the use of economic power and of leisure, the existence of which has been exploited by extremist movements. Unless that is done, no political superstructure and no expression of ideals can save Western civilization from disintegration.

Much progress has recently been made towards the establishment of world economic security, particularly in respect of the basic raw materials and foodstuffs. Wheat, beef, sugar, tea, whale-oil, rubber, tin, steel, aluminium and other commodities are already controlled on a world-wide or a European basis, although most of the schemes are still very young. These schemes require extension and improving by securing their joint control by consumer and producer interests, and providing buffer pools under disinterested management, and by making them accountable to an international supervisory authority, such as a Permanent Cartel Commission of the League of Nations. Other steps in the same direction would be the establishment of international public utility corporations, comparable with the Tennessee Val Authority, for backward territories, and the provis of international machinery for rendering raw mater available on special terms for particular backw areas, victims of aggression, or in times of natio disaster, etc. The creation of international mechani for rural loans, grants-in-aid and price insura schemes are other measures suggested to relieve want and insecurity of primary producers..

The idea of a division of the world into indust countries and a much larger group of colonial prim producing countries is mischievous, and indust development of all countries within their econo limits should be encouraged. Finance should subordinated to trade and economic developme Again, the systematic development of social servi accompanied by competent economic and finan policies, would be a powerful aid to world order could greatly increase the productivity of peop burdened with ill-health. In education, as in organization of the creative use of leisure or development of colonies, there are large opportuni for international effort.

The logic of events in the economic and so fields is compelling an international approach thereby inducing a reconsideration of the relat between nationalism and wider groupings. On question of the federalization of Europe, the bro sheet touches but scantily, pointing out that our must be to create political forms out of which a f developed federal system could easily emerge wh the necessary degree of economic and political hom geneity in Europe has been attained. The probl of European order can and should be isolated wit the problem of world order. Settlement of the f would simplify settlement of the second, particula as large areas in other continents are Europ dependencies.

The term European order in itself raises question, what is Europe, whether it should incl or not Great Britain or the U.S.S.R., for examp No treaty or political mechanism can provide s stitutes for courage, foresight, intelligence integrity, but it is important that the settlement a the war should both express and further the u of European civilization by a suitable mechanism, economic stimuli, by education and leadership.

The broadsheet accordingly proposes that settlement should include not only provision common institutions and common funds, but also formulation in broad terms of the essential conditi of European civilization, backed by organ publicity, as strong and as effectively watched as police arm. The establishment of a standing Europ- Council in appropriate relation with the League mi lead to a start in financial and economic affairs. would involve, however, a common policing age for Europe or part of it, and also a specific age for economic and social reconstruction, adequa financed. Many functions such as the improvem of communications, credit facilities, health servi education and research could be promoted m effectively by a European agency than by a hos national agencies.

THE COLONIES AND FOREST ADMINISTRATION

BY PROF. E. P. STEBBING

his Annual Forest Administration Report for 1938* the Conservator of Forests, Trinidad and bago, summarizes the forest policy in force. The uses merit repeating here, for though they have n current in forest management in the British pire for several decades, they have often proved be pious platitudes rather than a carefully ught-out planning to which the Government cerned intended to adhere rigidly. The clauses :

'(1) The permanent reservation by the Crown of tably situated areas of forest of a total acreage ficient to supply the benefits necessary for the lfare of the community—indirect benefits in the m of the maintenance of climatic conditions for icultural crops, preservation of water supply, pre- tion of erosion and flooding, and so on, and direct efits in the form of the supply of forest produce.

The management of these forests in such a way to encourage the fullest possible utilization of ir products on the basis of a sustained yield.

Such improvement of the existing growing stock will enable the Colony in the future to become least self-supporting in lumber."

here is nothing new in this. It may be found in form or another in the forest reports and memo- da of every Colony. In the past, how much of se praiseworthy aims has been effected ? It may admitted that the Forestry Department in Trinidad the past decade or so has received support from Government which has enabled progress to be de in a correct forest administration. But even e the forestry question appears to be regarded as a whole but as applying to parts of the country y. It is said that the general position with regard forest reservation is eminently satisfactory except the western portion of the Northern Range. In district apparently the greater part of the land a has for many years been under private owner- p, and until recently was mainly covered by cacao, est or second growth. The Conservator, on the ject of this area, continues as follows :

'In the present depressed state of cocoa, land ners are renting out increasing areas of steep hill- es to agricultural peasants, who grow field crops, h as maize, tomatoes, etc., thereon, under a tem of shifting cultivation. These peasants prefer highest, steepest, and most inaccessible portions the hillsides, as the danger of loss of crops by edial larceny is thereby lessened. The abnormally h rainfall of 1938, coupled with the increase of arings, was productive of erosion, flooding and dslides to an unusual degree, and revealed clearly dangers of the existing situation. The problem is ler investigation by the Lands Advisory Com- ttee."

his description might equally apply, taking local ditions into consideration, to parts of West or t Africa, the Malay States, the Dominion of South ica, and elsewhere.

It is admitted that the utilization of local forest produce in Trinidad has not reached by a long way the maximum production permissible, either in the more or less pure mora (*Mora excelsa*) forests or in the natural mixed forests of the Colony. In the latter the complaint is made that the high cost of exploitation, owing to their small volume-production per acre of marketable species, is a factor contributing to the Colony's dependence upon imported soft woods. From a perusal of the report it would at first sight appear that this latter was a new problem. But it is one which has been in the past, and is at the present day, facing the forester in charge of tropical broad-leaved forests the world over. It is the business and duty of the trained forest staffs to devise methods of successfully dealing with this problem. But they require their Government to have a fixed forest policy, to maintain an adequate forest staff not subject to repeated fluctuations, and to make available adequate grants of money for development.

During the War of 1914–18, the Colonies and their forest services were offered a great opportunity. Imports of foreign timbers, chiefly softwoods, were cut off. They had to depend upon their own resources. Most of them realized their own weakness and incapacity owing to the paucity of their forestry staffs. These have been considerably strengthened since then, though in many cases they fall far short of what is required.

The Colonies are now offered a second chance. It may be suggested that the work which should be required from the forestry staffs in all the Colonies during the continuance of the war should proceed on two main lines : (*a*) Map and report all areas in the Colony subject to any and all forms of erosion, whether forest or agricultural (that is, in the form of shifting cultivation) ; (*b*) carry out an enumeration survey or stock mapping in all forests accessible, and likely to be accessible by means of a grant to open out communications, on a 5 per cent enumeration basis, of such species and only such species as from their locally known qualities are likely to prove saleable, over and above the timber species already of marketable value.

This work of primary importance to the Colony concerned has not been carried out in a detailed and concentrated manner, as is well known. The finance departments of the Colonies have not been able to see beyond the annual revenue produced from the forests ; the staff have frittered time away over this revenue-hunting business ; or in experiments with small areas of plantations, fuel and otherwise, necessary as this work may have been ; and so forth. Since the War of 1914–18, a quarter of a century has passed and but small progress in the correct conservancy of its forest estates has been made by the Colonial administration as a whole. They are now given a second chance, with all the advantages of having clearly before them the opportunity lost twenty-five years and more ago. Will they profit by the lesson of the past and take it ?

---

* Council Paper No. 48 of 1939. (Trinidad : Government Printer, 9.)

ORIGIN OF DEFECTS IN COPPER CONDUCTORS

MR. J. E. DEERING contributes a useful article on the origin of defects in copper conductors to the *Electrical Review* of October 3. When hard drawing became a common practice, copper wire became a practical substitute for galvanized iron wire for overhead telegraph and telephone lines. The effect of the process was to raise the tensile strength of copper from 6·5 tons to 20 tons per square inch, which is almost equal to that of wrought iron, whilst its resistance is only about one-sixth. The effect of the cold drawing of copper is to make its resistivity only about 3 per cent higher than that of standard annealed copper.

Most contracts for the supply of copper wire quote the British Standards Institution specification, which states that the wire shall be approximately circular in section, smooth, uniform in quality, pliable, free from scale, inequalities, 'spills', 'splits' and other defects. Mr. Deering states that representatives of purchasing firms engaged upon the inspection of copper wire may be able to detect physical defects and yet are often unable to detect their origin. The following consideration of the different stages of manufacture will greatly facilitate the tracing of the causes of shortcomings.

During its passage through a succession of rolls after it has been ejected at white heat from the furnace, a copper billet, initially measuring 6 ft. by 4 in. by 3¼ in. and weighing 250 lb., increases in length as its cross-section diminishes. It emerges from the rolls at a greater linear speed than that at which it entered, for it not only takes up the speed of the rolls, but is also squeezed forward by an amount corresponding to the reduction in cross-sectional area. Rapid operation is necessary, as it prevents too great a difference in temperature of the metal from one end to the other, causing sometimes 1¼ per cent variation in the tensile strength of the wire.

To ensure a reasonable temperature throughout the rod before being drawn into wire, it is 'roughly annealed' by heating at 1200° F. and quenching with water. It is then pickled in dilute sulphuric acid to remove mill scale. During the rolling, the shape the cross-section is varied from pass to pass, fo the section were circular throughout fins would produced ; these would be bent over in the next p to form 'cold shuts', which might be below the surf for a distance, and possibly remain throughout complete process. A combination of shapes—squa ovals and rounds—is therefore used, and this kne the copper, rendering it homogeneous and ductile

The next stage is the breaking down of the rod pulling it through a dieplate with 12–18 holes. dies are usually of steel, but for copper cast iron sometimes used. For drawing long lengths of wire, diamond dies are occasionally employed. E hole has two zones—a short tapered one and a b mouth leading up to the approach. The walls of latter must be quite clear of the entering wire, wh might otherwise cause the metal of the die to drawn forward and piled up in the throat.

A departure in circularity in section may oc during wire-drawing, if the wire has slipped on drum of the coiling block, resulting in a 'flat' on surface through rubbing. Lack of smoothness sometimes due to the same cause. Non-unifo quality is traceable to impurities in the ore its Absorption of gases giving rise to blowholes wl the ore is being smelted into billets may also occ If during rolling a rod crowds a pass and iss with fins, these may become laid into the rod s show up as 'spills' on the surface. These are elimina by 'scalping'.

The origin of 'splits' occurs in the smelting sta If a fresh supply of metal is poured into a la which already contains a small amount of mol metal, the two will not mix or weld together. T seam or seal so formed will remain throughout rod or wire being rolled and covered in later stag so that it may appear on the surface at odd interv Two interesting photomicrographs are shown a high-conductivity copper rod and of a sect of the same rod after it has been made into ha drawn wire.

BELGIAN EARTHQUAKE OF JUNE 11, 1938

THIS earthquake has been studied by O. Somville, chief of the Belgian Seismological Service (*Annales de l'Observatoire Royal de Belgique*, Série 3, 2; 1939). On June 11, 1938, at midday by the public clocks near the epicentre, an earthquake was felt in Belgium, North France, Holland, North-West Germany, Luxembourg and South-East England.

The shock reached intensity VII on Sieberg's modification of the Mercalli-Cancani Scale in central Belgium where it was strongest, and displaced tiles as far away as Herne Bay in England. The earthquake was the most intense of approximately 140 experienced in Belgium since the year 1086. the Belgian Observatory at Uccle the Wiech mechanical instruments were thrown complet out of gear, though the long-period Galit instruments with galvanometric registration gave distance as between 50 and 60 kilometres fr Uccle and suggested that the epicentre was to north-west. This latter proved incorrect, as epicentre by later calculations turned out to between Audenarde and Renaix, almost west Uccle. On a basis of 3,570 communications, isos were drawn using Sieberg's modification of Mercalli-Cancani Scale, and two maps showing disposition of these are figured in the text, together with a map showing the point intensities in Holland.

It appears that altogether 17,550 chimneys were damaged, 3,000 in Courtrai alone, which represents 10 per cent of the possible number. There was no loss of life though ten people were slightly injured. Most people heard a sound as of the passage of a heavily laden cart, and several experienced two hocks, of which the second was the stronger. By the method of hyperboles the epicentre was found to be at geographic co-ordinates 50° 47′ N., 3° 35′ E., with an uncertainty of 4 or 5 km. A diagram of the determination is given in the text. The depth of focus, using the Mohorovicic tables of $\overline{P}$–P_n and Gutenberg's corrections, was of the order of 45 km., and this was confirmed by the formula for near stations.

$$\text{Time of propagation of } \overline{P} = \frac{\sqrt{h^2 + \Delta^2}}{V},$$

where h is depth of focus, Δ is epicentral distance both in kilometres, and V is speed of wave taken as 5·7 km./sec.

The initial time was calculated to be 10h. 57m. 42s. G.M.T., and it was found that north-east and south-west of the epicentre compression was registered first, whilst in the other two quadrants dilatation was initially experienced. Readings for P_n P^* $\overline{P}$ α S_n and S pulses for twenty-four stations in Europe are given together with a graph, and seven of the seismograms are reproduced. Six notable aftershocks have been noted.

SACRED FEASTS OF THE FOX INDIANS

IN "Ethnography of the Fox Indians" by William Jones, edited by Margaret Welpley Fisher (*Bureau Amer. Ethnol., Bull.* 125; 1939), certain passages are entatively identified with the contents of a sealed packet recording "ancient mysteries" of the Fox ndians, reported to have been among papers in the ustody of the author's father (see NATURE of November 25, p. 914). These passages deal with "The Sacred Feast".

One kind of sacred feast is held in autumn, winter or spring. A man kills a deer and decides to pray. He informs a number of members of his own gens, say, the Eagle gens, of his intention, and each brings ood, maple sugar, pumpkin, corn, etc. The prayer s held during the day, beginning in the morning. Waiters come to the lodge of the man getting up he feast and prepare the food; and invitations are then sent to others outside the gens. When the uests appear they find the Eagles waiting for them, seated at one end of the lodge, with the medicine bags spread out in front of them. They drum the air slowly with gourd rattles and chant songs. Before the first singing and while the food is cooking, the Eagles say to themselves to which spirit the food s sacrificed. The sprinkling of tobacco accompanies the mention of each spirit's name. A period of silence follows, then when the food is cooked the second singing and the eating begin. All food must be eaten before the fourth singing begins, and at the close of the fourth singing all the people disperse.

At the summer feasts in the summer bark lodges there is added dancing. As soon as the corn ripens, thanksgiving feasts are held to which each gens nvites members of the different gentes. These ervices are religious, preparatory to the thanksgiving ances. Each gens holds two services at which newly athered corn is eaten as well as the flesh of a dog illed for the purpose. The inviting gens does not eat, but does the praying to the manitou for his goodness in giving them corn. These services are purely religious and no one comes unless nvited.

In the same manner in the dances, such as the Wolf or Eagle Feast dances, dog, the principal thing aten, is an offering made to Manetowa to invoke his pleasure and presence at the dance, and no one comes to the dance unless he comes with the thought of coming into the presence of Manetowa. There is an atmosphere of sacredness; all enter silently and slowly, and there is no hilarity. During the dancing the men not taking part smoke or chew tobacco, while the women chew but do not smoke. The use of tobacco forms part of the rites to invoke Manetowa.

A feast is often held for the spirit of sickness so that he may not bring sickness. He has the power of granting long life. He is a manitou. Once a Winnebago—among the Winnebago, disease-giver was the most sacred of all their spirits—is said to have had the power of driving away the spirit of sickness. When the people were all dying of smallpox, he rode a white horse painted green and decked out gaily. He would run towards a house, yell at the spirit within, and strike against the lodge. This he did to drive out the spirit, and thereby gained many gifts.

Before a run is made on the buffalo, every camp makes a sacred feast to the buffalo, in which the food must be pumpkin or corn or maple-sugar; always sugar together with the other two if possible. Dog or any other kind of meat is not used. The feast is made as soon as the hunters know they are in the vicinity of the buffalo.

In the buffalo dance the men and women imitate the run and movement of the buffalo when in flight. The leader in the dance has his head covered by a buffalo mane. Dog, corn and pumpkin are eaten.

The Mowitihagi, "Dirty Little Ant", otherwise known as "Those who worship the spotted calf", is a society in which many of the members belong to the Thunder gens. It is a most important society, ranking with the gentes in some of the buffalo ceremonies. At its dance a small image of a buffalo made of stone is brought out from the bag in which it is usually kept and placed on the floor halfway between two fires. It is about 8–10 inches long and 6–7 inches high, of red stone, and in every respect a representation of a buffalo bull. It is said to be alive and a manitou. In the dance, tobacco is offered to it. It is brought out twice a year only in the sacred feast of the Mowitihagi.

SCIENCE NEWS A CENTURY AGO

The Observatory of the Rajah of Travancore

"We have seen with not a little pleasure," said the *Athenæum* of December 7, 1839, "an Astronomical Ephemeris, printed at the press of the Rajah of Travancore, and calculated for the meridian of the observatory recently established at Trivandrum, the capital of that State. Those who feel an interest in the intellectual progress of the people of India must be gratified to learn that the computations for this work were all made by native youths of Travancore, who received their education at the free school maintained by the Rajah. His Highness . . . came to a determination, in 1837, to establish at his capital an observatory of a superior kind; with the double view of affording his aid to the advancement of astronomical science, and of introducing, by its means, correct ideas of the principles of this science among the rising generation under his government. For the situation of Astronomer he chose Mr. John Caldecott, who, aided by Colonel Fraser, the British Resident at Travancore, decided on the plan of the building which is now erected, and which stands in latitude 8° 30′ 35″ N., longitude 76° 59′ 45″ E. Hitherto the observations have been carried on with small but excellent instruments belonging to Mr. Caldecott; but his Highness the Rajah intends to furnish it with the finest instruments to be procured in Europe, having, for this purpose, secured the services of T. Jones, T. Simms, and Dollond. . . ."

John Caldecott, who was born in 1800 and died in 1849, was the commercial agent to the Government of Travancore, but after the erection of the observatory devoted himself entirely to science. He was elected a fellow of the Royal Society in 1840.

Vegetable Monstrosities

THE issue of the *Medical Times* of December 7, 1839, contains the following note: "At the Linnean Society on December 3 the secretary read a communication from the Rev. Mr. Hicks describing some vegetable monstrosities recently met by him in the neighbourhood of York. They consisted in a union of two or more flowers into one, without any lines of junction whatsoever being visible, and in a multiplication of the stigmata, the pistils and petals of the plant—what De Candolle has denominated, with great propriety, an unnatural excess of fructification. In one or two species of iris and in a specimen of scrophularia nodosa, or sulphur wort—all which were exhibited to the meeting—the malformation of structure was strikingly apparent."

Iron Smelting in India

AT a meeting of the Asiatic Society on December 7, 1839, extracts from a journal by Captain Jacob, of the Bombay Army, were read. One of these referred to the process of iron smelting in the Mahabaleshwar Hills. The smelting was carried on in the most primitive way imaginable. The ore was dug from pits 20 or 30 feet deep, and in appearance was like rough gravel. The furnace was a hole in the earth lined with charcoal, and fitted with a clay oven. The bellows were two goat skins, worked alternately by the hand, and terminated in a clay pipe, which formed the nozzle. About three hours were required to smelt 12 seers of ore, producing about 5¼ seers of a rough, drossy, impure iron, which lost about 2 seers more in being worked into its destined form. Thi quantity sold in the bazaars for a quarter of a rupe (less than a penny a pound). Better English iron wa finding its way into the hills, at the same price o even cheaper.

Mortality in Malta

THE issue of the *Medical Times* of December 7 1839, contains the following information: "From th absence of all malarious agencies the character o this island has been supposed exceedingly salubrious The returns adduced, however, show that compare with Britain, the mortality is as 25 to 22 per 1,00 of all ages: among the troops during the 20 year antecedent to 1837 it averaged 18$\frac{1}{10}$ths and th admissions to hospitals 1·142 per 1,000 of the forc annually. Passing over the ordinary forms of disease such as fever, ulcer, syphilis and others whose fatalit in the tropics is proverbial, the prevalence of disease of the lungs, in a climate hitherto supposed particularly favourable to persons predisposed to them is marked as a singular circumstance. Consumptio in particular carries off a larger population, both civ and military, than it does in the whole United Kingdom, for it appears by the bills of mortality that tw thirds of the deaths are from this disease."

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on c before the dates mentioned:

TEACHER OF ENGINEERING SUBJECTS—The Principal, Technic Institute, Ladywell, Dover.

UNIVERSITY GRADUATE to direct Institute of English Studie Sofia—British Council, 3 Hanover Street, W.1 (December 14, quotin 'Sofia').

TEMPORARY FORECASTERS, Grade II (Male) in the Meteorologic Office—The Under-Secretary of State, S.2 b. (Met.), Department Q.A Air Ministry, Adastral House, Kingsway, W.C.2.

TEMPORARY METEOROLOGICAL ASSISTANTS (Male) in the Meteor logical Office—The Under-Secretary of State, S.2.B. (Met.), Department Q.J., Air Ministry, Adastral House, Kingsway, W.C.2.

SCIENCE AND THE WAR

T. ANDREW'S DAY, November 30, saw the customary anniversary meeting of the Royal ociety, held this year, not at the Society's rooms Burlington House, London, but at Trinity llege, Cambridge, where the offices of the Society ere removed on the outbreak of war.

In the general part of his anniversary adess, Sir William Bragg spoke on the position the Royal Society, and, by implication, of men science generally, in relation to the war. He inted out that a very large number of fellows the Society are serving the nation in different pacities, but he is clearly not satisfied that full e is being made of the scientific resources of eat Britain. Sir William thinks—and his ews will meet with general agreement—that spite of the widespread acknowledgment of the fectiveness of science, the ways of using science d scientific men are being discovered too slowly. here can be little doubt that our administrators, a body, lack that knowledge of the fundaentals of science which would enable them to ake better and speedier use of its fruits. Sir illiam put this basic knowledge in the form of ur "propositions":

"1. Science, that is to say, the knowledge of ature, is of fundamental importance to the ccessful prosecution of any enterprise."

"2. Science is of general application. There is t one science of chemistry, another of electricity, other of medicine and so on: there are not even istinct sciences of peace and war There is only e natural world, and there is only one knowledge f it."

"3. Fruitful inventions are always due to a mbination of knowledge and of experience on e spot."

"4. There are difficulties peculiar to the application of science to war purposes", in that it is not easy to maintain during times of peace the necessary connexion between this special application and the general body of science.

These generalizations are well worth putting on record, for their significance extends far beyond the present times of stress which have provoked them.

Sir William then turned to consideration of the way in which more use might be made of science. He believes that, for the present, "the most successful ways of using knowledge are personal and elastic", rather than through a formal Ministry of Science, and he threw out the suggestion that the Royal Society, possibly through a selected small group of fellows, might be used as a regular consulting body, giving advice as required and also being kept so informed of the progress of events that "it might foresee occasions and needs".

The suggestion should be given very earnest consideration. The task of selecting a suitable group of fellows of the Royal Society for this purpose would not be easy, but there is no gainsaying that the Society has a unique range of consultant experience on which it can call. In addition to the direct use of such a body, it may be suggested that close collaboration with the Central Register of specialists maintained by the Ministry of Labour in association with the Royal Society and professional institutions would have valuable consequences. In this way the Register might serve, not only as a source of scientific and other trained personnel, but also, as an index to the state of research in Great Britain, to suggest lines of investigation which may enable us, in Sir William's words, to "foresee occasions and needs".

DISCOVERY AND INVENTION IN WAR-TIME

APART altogether from limitations of resources and materials imposed by national needs and the diversion of scientific workers from creative or fundamental work to emergency problems of defence and the like, the impact of war is rarely favourable to scientific advance. War necessities may, and often do, stimulate invention, but they rarely favour, and indeed commonly retard, scientific discovery and the advance of knowledge. Even in such special branches as aviation, the War of 1914–18 actually retarded technical progress, and as has been pointed out in these columns from time to time, warped the development of civil aviation.

Under conditions of war, the conservation of resources, and above all of creative and fundamental thought and work, becomes a matter of prime importance, and we may well return with increased interest to the symposium on invention presented some years ago before the Institution of Mechanical Engineers, as well as to the highly suggestive study of C. Nicolle, "Biologie de l'Invention" (Paris: Librairie Felix Alcan), published in 1932. Although the symposium on invention was concerned primarily with the evolution of invention and the development and exploitation of invention relative to patent law and economic recovery, the broader questions of the place of invention in industry and its relation to scientific discovery received passing notice.

Even in regard to invention, we may not assume too readily that all is, and will be, well under war-time conditions. The needs of a time of emergency are apt to stimulate invention to solve day-to-day or urgent problems rather than the long-range problems, and particularly those involved in the reconstruction and re-integration of social and economic life after the war. If the latter needs and problems are entirely neglected, there are likely to be many gaps in our knowledge and many unsolved problems which will hinder us reaping the full benefit of our war-time effort. Nor should it be forgotten that it is not only from *ad hoc* research or investigation that the solution or clues to the solution of even the most urgent problems have always come. Fundamental research has a stimulating and fertilizing value which should make us chary of starving it even in the direst necessity.

M. Nicolle's little book, however, made a m serious attempt to probe the theory or mechani of scientific discovery, to which some attention w given in the symposium. In spite of frequ discussions, we are little nearer to the und standing of this question than in the time Bacon. Fundamental creative ability may inde defy analysis, but a knowledge of the conditi which encourage or stimulate it is worth whi all the more when the need to conserve resour is most imperative.

It is recognized that discovery precedes inv tion possibly by long spans of time, and inventi itself presupposes knowledge based on experim and observation. Broadly speaking, as Mr. H. Dickenson pointed out in the symposium question, a discovery is the apprehensi of the order of Nature, while invention the guidance of the known forces of Nat into new channels for the benefit of man. Wh we are primarily concerned with here, however, the ability to evolve new schemes or contrivanc commonly called inventiveness, and the fact which are favourable or unfavourable to t exercise or development of this faculty.

Many factors have similar influences on bo invention and the more creative act known discovery. The initial effort required either creative thought or inventiveness can be repress or prolonged by excessive knowledge. The deade ing effect of the abundance of technical a scientific literature to-day has frequently be the subject of comment, whether from the poi of view of encouraging excessive specializati and pre-occupation with the details of a narr field or from the mental indigestion it may cau

This position, however, arises in part from t chaotic condition of scientific and technic literature, and the failure of scientific workers organize a really adequate and effective abstracti service, with the advantages which the exp handling of such literature and the eliminati of duplicated effort would afford. The stringen of war-time conditions in regard to paper a printing may yet supply an added stimulus whe the rational motive has been insufficient to ov come inertia or prejudice.

Even when allowance is made for such retardi influences, it has to be admitted that fundament ative ability defies analysis. Although, at present time, a wide experience is more essary than ever, conscious thinking out science is a process rarely if ever leading to el results. As Sir J. J. Thomson observes in ecollections and Reflections": "New ideas come re freely if the mind does not dwell too long one subject without interruption. It is, I think, general experience that new ideas about a ject come when one is not thinking about it the time though one must have thought about good deal before. It is remarkable that when as come in this way they carry conviction with m and depose without a struggle ideas which viously had seemed not unsatisfactory".

he creative mind concentrates more or less ensely for a less or greater space of time upon roblem for which no solution is known. A new l correct solution comes to it in exactly the ne way as a forgotten name or fact often comes us after we have cudgelled our brains in vain it. Just how or what determines the incidence the new idea remains an unexplained mystery. can only note the predisposing factors which mulate it or appear to accompany it.

ne of these has already been noted— break in conscious thinking about the ject. Dr. H. S. Hatfield pointed out in the ne symposium that in early youth the power ssimilation may afford a criterion. The creative d frequently has much less power of assimila- n, but along some particular line it actually s ahead of the matter presented to it, re-invent- what is known. Initiative is another charac- stic, even if we dissent from the proposition t genius is merely a capacity for taking infinite ns. It is rare, however, to find genius without t capacity, at any rate in directions which ve its ends.

gain, creative work is rarely accomplished by steady round of daily hours most favour- e to routine work. It has mostly been omplished in violent bursts of overwork at h pressure, alternating with periods of com- ative idleness in which the unconscious mind able to order its content. Problems are not ved more slowly by easier going : rather they not solved at all unless the attack reaches certain intensity. The creative act, as M. olle points out, is essentially irrational. We not impart merely by training the sense of ues and the capacity to discriminate instan- eously between essential and non-essential. We can only hope to supply the conditions or opportunities in which they flourish and develop and in which they can be most readily stimulated.

Creative genius, again, is something more than intelligence. It is not simply the acquisition of new facts and their systematization. Such powers may be possessed to a high degree by minds incapable of creative originality. It is indeed true that if genius is to accomplish anything effective, it must be accompanied by good sense, and that, even so, collaborators may play an indispensable part by keeping the creative spirit in touch with realities and supplying just that capacity to work out the consequences or practical applications of the discovery with which genius is apt to be too impatient to trouble. Anything that endangers its spontaneity or limits its freedom, however, threatens the creative spirit. True though it may be that genius may triumph over any misfortune or obstacle, it is only those who succeed of whom we hear.

In science, no less than in art, creative work flourishes in an atmosphere of sympathy and enthusiasm, where the mind is quickened and encouraged to expand. We lay constraint or even discipline on the truly original at our peril. Such minds are rare, but it is difficult to distinguish between latent genius and the normal intelligence. It is one of the dilemmas of wartime that we must seek to preserve for the creative few the full freedom of thought and work essential, while the many accept the discipline and constraints demanded in the national interests. More, rather than less, in war than in peace, the price of liberty is eternal vigilance, and no severer task lies upon the shoulders of scientific workers than that of seeing that all the vigour which they bring to national service in its myriad needs, and the readiness with which they accept sacrifice and discipline with their fellow citizens, shall not be allowed to impair for one moment the disinterested search for truth They who claim to be defending the cause of freedom and truth must see to it that, within their ranks at least, the quest for truth is unimpeded, and that no political considerations are allowed to fetter discovery or exposition of its results when these are prompted by the disinterested desire to enlarge the bounds of knowledge. Ultimately it is in the truths won in many fields of knowledge—physical, economic, social—by creative minds that alone we can build the new social order which will make the present sacrifices worth while.

THE COMPLETE CORRESPONDENCE OF LEEUWENHOE

Alle de brieven van Antoni van Leeuwenhoek (The Collected Letters of Antoni van Leeuwenhoek). Uitgegeven, geïllustreerd en van aanteekeningen voorzien door een Commissie van Nederlandsche geleerden (edited, illustrated and annotated by a Committee of Dutch scientists). Deel (part) 1. Pp. 454 + 40 plates. (Amsterdam: N. V. Swets and Zeitlinger, 1939.)

IN 1931 when the Royal Dutch Academy of Science and the leading medical authorities in Holland were considering how best to celebrate the tercentenary of the birth of Leeuwenhoek in 1632, it was resolved to prepare and publish a complete annotated edition of his scientific writings, accompanied by English translations. English-speaking people will be grateful for the translations, and will appreciate cordially the compliment implied in this decision. The Royal Society of London from the very outset gave valuable encouragement to its humble Dutch correspondent, and in doing so displayed the soundest judgment, since Leeuwenhoek's earliest letters by no means foreshadowed the important results he was later to achieve; and this is all the more surprising when it is remembered that his first letter was written at the age of forty.

The present instalment of this difficult and important enterprise, the first of twenty, is an imposing quarto volume which includes a general introduction and preface by Prof. G. van Rijnberk, the president of the committee, the first twenty-one letters written between April 1673 and February 1676, in Dutch and English versions, a discussion by Dr. A. Schierbeek of Leeuwenhoek's micrometric methods as related to modern standards, brief notes on the persons mentioned by Leeuwenhoek and the annotators, bibliography, indexes in Dutch and English, and thirty-nine plates based on photographs of the original drawings which have survived, and also some modern figures which the committee considered essential to elucidate the text. The work is well printed, but the paper used in the plates is so friable that in the reviewer's copy one sheet had broken at the hinge and worked loose before the book was used. Also we suggest that it is a mistake to reproduce line engravings as half-tone blocks—the line block gives a better result, is less costly, and can be printed on durable paper. It must be allowed that the illustrations of the work generally admit of some improvement. In particular the figures of Leeuwenhoek's microscopes are unworthy of an edition which aspi to present to us the *complete* Leeuwenhoek. 1921, Roemer published photographic reproducti of the Utrecht microscope which were admirabl

Of the twenty-one letters now listed one never been available and its contents are the fore unknown, and two others are merely coveri letters of only a few lines each. Hence this volu deals with but eighteen of the relevant letters. has, nevertheless, taken several years to prepa so that unless the rate of publication can materially accelerated the entire correspondence some two hundred and eighty letters can scarc appear in the lifetime of the present generati A similar Dutch undertaking—the works of C Huygens—was commenced in 1888 and is proceeding. All the eighteen letters above m tioned were published in Holland *in extenso* 1931 with English translations, except those whi had been more or less completely translated in *Philosophical Transactions*. The present volu therefore, contains nothing new apart from th passages which were rejected by the *Philosophi Transactions* translator. These omissions pr to be of little importance, except perhaps section on digestion which forms the conclusi of letter 18 (12).

The first concern of the English reader will with the accuracy of the translation. Most Du biologists speak and write English so well that would seem unnecessary, and even ungracious, offer them any assistance. Nevertheless, th are criticisms to be met, and we would stron urge the Dutch committee to anticipate them submitting the English version of all fut volumes to the censorship of one of their Engl friends. The translation, or rather the interpre tion, of Leeuwenhoek, due largely to his cha and inexact manner of expressing himself, can quite speculative and laborious. We had hop that these difficulties, magnified in Great Brit by lack of familiarity with the language a customs of seventeenth century Holland, could a would be resolved by a Dutch-speaking committ When the *Philosophical Transactions* transla found himself in deep waters, as he frequently d he took refuge in a literal translation of Leeuw hoek's words. *That*, however, is the way of e and perplexity. In Dobell's book the proble were faced with uncompromising determinati and precise knowledge, and most of them yield to this treatment. Our Dutch friends, on the ot hand, have made the mistake, as we think, pting the orthography and faulty text of the *ilosophical Transactions exactly as printed*, not m excluding typographical errors. Obvious wnright mistakes are of course corrected, and se parts which were omitted in the *Philosophical nsactions* are translated into *modern* English. e result, leaving us as it does practically where were, is somewhat disappointing.

We admit that to edit the whole of the Leeuwen- ek correspondence with the meticulous scholar- p of a Dobell would be a stupendous task, and ld not be entrusted to one man, but this is a e where the counsel of perfection is not an ernative but the only course to follow. In sequence of the method adopted by the Dutch mmittee, the *Philosophical Transactions* letters presented to us in a hybrid dialect which n an Englishman cannot fully comprehend thout recourse at times to the Oxford ctionary, nor is any attempt made to parallel distinctive style of the original. Moreover same word may have a different connotation seventeenth and twentieth century English. cannot but feel that, if only for the sake of formity, the *Philosophical Transactions* versions uld have been corrected *and* modernized, so to reduce the whole text to the same idiom. A few examples as reprinted by the Dutch mmittee from the *Philosophical Transactions* ll illustrate the point: p. 33, "Whence I am ne to collect" [inclined to the opinion]; p. 107, some few places [in the liver] the blood lay n-wise . . . dispersed through the Liver out the veins" [? veined like marble]; p. 109, hese Globuls I judged to be blood, and that, cking our body with a pin without hitting a in, the bloody Globuls did issue from between se [muscle] filaments"; p. 123, "the red obuls agitated pesle-mesle, and as if each obul had yet a second motion, and that about axe" [pell-mell and axis]; p. 197, "the holes the Nerve were not round nor so regularly ited by one another" [punched]; p. 303, ppeared to me in *my* Microscope, of the thick- s of a great Bread-knives back"; p. 305, "it sed but very slowly through blew Paper"; p. 7, "then will each degree of hardness . . . se more or less sharpness of taste upon our ngue, and consequently produce a su[i]table eration" [specific reaction]. In this passage the itors have modernized the spelling of "sutable", d in another place they have substituted "I pared" for "I did myself prepare", but why y should have done so in these and a few other es whilst ignoring all other archaisms is not plained.

Here are some examples of their modern English which objection could be taken: p. 173, "the yolk-cells give these eggs a troubled [turbid] appearance"; p. 209, "examination of the optic nerve by picking [teasing] it"; p. 217, "post-mortal changes in the optic nerve"; p. 221, "inhomogenous nature of tobacco-smoke"; p. 223, "containing in its inner hollow a grain of gun-powder"; p. 227, "the sting of a scorpion is not letal" [use of German instead of English equivalent]; p. 349, "egg-pod" [shell membrane]; p. 355, "That is why it may make [give] the impression of a cavity"; p. 357, "the medulla often contains air, and then appears to be black, owing to a total reflexion [!] of the light". To translate "Heer liefhebber" as "gentleman amateur" is to carry literality too far. "Philosopher" or even "virtuoso" (as on p. 303) would be more suitable.

Apart from a number of minor misprints the following points should be included in the list of errata and addenda: pp. 41 and 73, Letter 5 (3) as published in the *Philosophical Transactions* includes a part (par. 6) of Letter 2; p. 45, the plate of the bee in the Lancisian library in Rome is dated 1625 and bears the name of Stelluti; p. 75, "And exhibiting my Blood to myself in very small parcels, the globuls yielded very colour"—the *Philosophical Transactions* version which is followed has it correctly "very little colour"; p. 151, the belief that nerve fibres were tubes which transmitted fluid contents survived until the middle of last century; p. 155, the whole paragraph refers to the vagus and none of it to the optic nerve—in the latter part of the paragraph Leeuwenhoek was perhaps describing the pulmonary plexus of the vagus; p. 175, the suggestion that Leeuwenhoek discovered the eggs of the liver-fluke in the gall bladder *of the rabbit*, but not the oocysts of Eimeria as suggested by Dobell, is so highly improbable as to be unacceptable without further evidence; p. 213, dark ground illumination was undoubtedly described by Hooke in 1678, which lends colour to the conjecture that Leeuwenhoek may have hit upon it in 1675; p. 219, sections as aids to anatomical study were used before Leeuwenhoek by Boyle (1663), Hooke (1665), and Grew and Malpighi (1672); p. 331, the attribution of the discovery of Daphnia to Goedart by Swammerdam is difficult to explain but nevertheless an error, and the reference to the "Historia Generalis" 1665, Tab. VI, should be 1669, Tab. I; p. 383, in discussing Leeuwenhoek's estimate of a hairsbreadth the annotator has misunderstood a statement by Dobell, who did *not* assume that Leeuwenhoek's wig was made of human hair—in fact the contrary is expressly implied.

If some of the shortcomings of this work have been dwelt upon, it must not be concluded that its merits are not considerable and impressive. The defects we have mentioned are remediable for the past and preventable in the future. The discoveries of Leeuwenhoek are of such importance as to exact the highest standard of performance on the part of those who seek to do him honour. In the efflorescence of the arts and sciences which occurred in Holland in the seventeenth centu Leeuwenhoek occupies a commanding place, a therefore any commemorative edition of writings should reflect the universal reverence which the genius of this remarkable man is he

F. J. COLE

MINERAL NAMES

Descriptive List of the New Minerals, 1892–1938

Containing all New Mineral Names not mentioned in Dana's "System of Mineralogy", sixth edition, 1892. Compiled by George Letchworth English. Pp. vii + 258. (New York and London: McGraw-Hill Book Co., Inc., 1939.) 18s.

MR. GEORGE L. ENGLISH, well known to mineralogists all over the world from his long connexion with the firm of Ward's Natural Science Establishment at Rochester in New York State, has compiled from various sources an alphabetical list, with definitions, of all new mineral names not included in the sixth edition of Dana's "System of Mineralogy" published in 1892.

Beginning in 1897, the Mineralogical Society of Great Britain has published fourteen lists of new mineral names, compiled by Dr. L. J. Spencer and printed at the end of each volume of the *Mineralogical Magazine*. In each list the names were arranged alphabetically, but as the fourteen lists contain more than 2,100 names, it will be a great convenience now to have all the names available in one volume.

For several years the Mineralogical Society of America has had a Committee on Nomenclature at work. The final report of this Committee has recently been adopted by the Society, and Mr. English has been able to incorporate in his list the changes in names proposed. These changes fall under two headings: (1) those merely involving a different spelling from that adopted by E. S. Dana in the sixth edition of the "System of Mineralogy"; and (2) those calling for a definite choice between two alternatives both in common use among American and British mineralogists. It is satisfactory to note that a certain measure of agreement was reached between the American Committee and a committee appointed by the Mineralogical Society of Great Britain at a joint discussion which took place in Washington in 1933, and the only names of common minerals for which the spellings preferred by the United States mineralogists are not likely to be taken into general use here are: 'sulfur' for 'sulphur', 'hematite' for 'hæmatite', and perhaps 'feldspar' 'felspar'.

The spellings 'feldspar' and 'felspar' have bo been in general use in American and Brit mineralogical and geological books for nearly century and a half. The spelling 'felspar' w introduced in 1794 by R. Kirwan in the seco edition of his "Elements of Mineralogy". In first edition he had spelt it "feltspar" and "f spar", and he explained his change of spelling i footnote: "This name seems to me derived fr *fels* a rock; it being commonly found in granit and not from *feld*, a field; and hence I write thus, felspar." In this assumption Kirwan w wrong. The name was not German, but Swedi It was first introduced by D. Tilas in 1740 in t first volume of the *Transactions of the Swed Academy of Sciences*. It seems that Tilas wr "feldtspat" in his manuscript, but in the print paper the name appears with no fewer than fo different spellings on a single page: "feldt spa "feltspat", "fältspat" and "feldtspat". Linna used "fältspat" in 1748 and so did Cronstedt 1758. Contemporary German works gave bo "Feldspat" and "Feldspath", and in English find "field-spar" (1772), "feltspar" (Kirwan 178 "feldspar" (Hutton 1785), "fieldspath" (Bedd 1791) and "feldspat" (Wedgwood 1792).

Tilas had published no explanation of t derivation of his name, but it is believed to re to the abundance of the mineral in the tilled fie in the rapakivi granite district of south-weste Finland, and its derivation from the Swed "feldt" or "fält" (= field) is undoubted. J. Dana in his famous "System of Mineralog adopted the spelling "feldspar" from the st (1837) and this spelling has remained in gene use in the United States, while Kirwan's spelli "felspar" was adhered to in Great Britain. In t last few years, since the discussions with t American Nomenclature Committee, many miner ogists in Great Britain have adopted the spelli "feldspar", but this has not been accepted by t leading mineralogical and geological periodic Fortunately, whichever spelling is used, no co fusion in meaning will arise.

nleitender Überblick, Geschichtliches, Vor-
mmen. Pp. 122+iv. (Berlin: Verlag Chemie,
m.b.H., 1938.) 14.25 gold marks.

HIS part of Gmelin's "Handbuch" contains a historical account of the discovery and currence of the so-called 'rare earths', a descrip- n of their minerals and an account of their ographical distribution. The discovery of large posits of monazite sand in Brazil, in North and uth Carolina and in India has perhaps rendered e designation rare earths misleading, but it is in mmon use, although in this work the term cludes the elements scandium and yttrium as ll as the fascinating cluster of elements which idges the gap between barium and hafnium.

In spite of much previous work dating back to e year 1794, the mystery of this cluster remained solved until the work of Moseley on atomic mbers and of Bohr on atomic structure provided e solution. The number of elements was fixed fifteen, of which all but one are definitely known. e existing data about No. 61, which is called inium or florentium, are derived from X-ray ectral lines in the *L*- and *K*-series. The unusual similarity of chemical properties of the others is associated with peculiarities of atomic structure, the outer shells of electrons being alike in all cases.

The most characteristic property of the group is their paramagnetism, which begins at cerium and increases progressively to lutecium. This property is associated with the occurrence of valency electrons in the fourth quantum group. Moreover, whereas the basicity of the tervalent elements increases from aluminium to lanthanum, it decreases very slightly but steadily from lanthanum to lutecium. A similar increase and decrease is noticed in the dimensions of their ionic radii (the lanthanide contraction). No mention is made of the recent work of Klemm and Bommer, which reveals a periodicity of atomic volume with high peaks at europium and ytterbium.

Modern views on crystal structure have had an important bearing on the development of geochemistry. The rare earth minerals occur chiefly in granites and pegmatites, and their occurrence is determined more by lattice dimensions than by valency; the small ionic radius of aluminium seems to render it incapable of replacing rare-earth metals to form isomorphs.

A comprehensive table gives the proportions of the various elements in many minerals as deduced from spectral intensities.

MECHANICS OF SPORE DISCHARGE IN TERRESTRIAL PLANTS

ore Discharge in Land Plants
y Dr. C. T. Ingold. Pp. vii+178. (Oxford:
arendon Press; London: Oxford University
ess, 1939.) 7*s*. 6*d*. net.

R. INGOLD has for some time paid special attention to the discharge of spores, par- ularly in the group of fungi, stimulated as he atefully acknowledges by the important contribu- ns Prof. A. H. R. Buller has made to this subject his six volumes of "Researches on Fungi". Dr. gold's own publications have so far dealt only th fungi, but following up this interesting subject has examined critically the spore discharge of yptogamic land plants as a whole, and the esent volume deals with the Bryophyta and eridophyta as well as the Fungi. It is perhaps tural considering the inception of his investiga- ns that his latter group of plants receives preferential treatment, but we must remember also that the methods of spore liberation among fungi are more varied.

Reviewing these seriatim, the author deals with the water-squirting mechanism of the Ascomycetes and other fungi, with the discharge due to rounding-off of turgid cells, with the catapult mechanism of Sphærobolus and with the drop-excretion process of basidiospore discharge. The mechanism of this latter process is not as yet fully explained. Prof. Buller has stated that "it may be that the force of surface tension is used in some way to effect discharge". Dr. Ingold gives a very careful consideration to this suggestion and from his calculations concludes that there appears to be sufficient surface energy to discharge the spore: but that it is not easy to see how this energy could be mobilized to bring about the discharge. A final solution of the problem, he thinks, must be sought in a more intensive study of some cases of abnormal discharge which have been reported by Buller.

In connexion with the basidiospore discharge Dr. Ingold describes his observations, accompanied by excellent drawings, on the liberation of the basidiospores of Puccinia and also of the so-called "shadow yeast" *Bullera alba*, which from the nature of its spore formation must be included among the Basidiomycetes. In the Bryophyta he describes in detail the scattering of the spores from the open capsule of *Cephalozia bicuspidata* by the spring mechanism of the elaters released by water-rupture. This latter process is also dealt with in considering the spore discharge of the ferns and of Selaginella.

In concluding a final chapter given up to general consideration of spore discharge in Crypt gams, the author makes a plea for the expe mental study of this process in the ordina botany courses at the universities. The realizati of this very reasonable hope will be great facilitated by the publication of the book und review, which not only describes clearly the ma fascinating methods of spore discharge and disper found in cryptogamic land plants, but also co tains a large number of excellent illustrations, mo of which have been specially drawn to explain t various mechanisms of dispersal. The historical i troduction and the bibliography will be of gre value to students of this very interesting subje

DETERMINANTAL LOCI

The Geometry of Determinantal Loci
By Prof. T. G. Room. Pp. xxviii + 483. (Cambridge: At the University Press, 1938.) 42*s*. net.

PROF. T. G. ROOM uses the symbol $(|p, q|_r, [n])$ to denote the locus, in projection space $[n]$ of n dimensions, whose equations are given by the vanishing of the determinants of order $r + 1$ of a matrix (x_{ij}), of p rows and q columns, whose elements are linear functions of the (general homogeneous) co-ordinates in $[n]$. This he calls a determinantal locus; particular determinantal loci are the conic in [2] and the quadric surface, cubic curve and cubic surface in [3], with respective symbols $(|2,2|_1, [2])$, $(|2,2|_1, [3])$, $(|2,3|_1, [3])$ and $(|3,3|_2, [3])$. $(|p,q|_r, [n])$ may be *projectively generated* as the locus of the meets of the $\infty^{r(p-r)}$ sets of corresponding $[n-p+r]$'s of q projectively related $[n-p]$-stars, and, since $(|p,q|_r, [n])$ is the same as $(|q,p|_r, [n])$, there is a conjugate projective generation obtained by interchanging p and q. Thus the cubic curve in [3] may be regarded either as the locus of the meets of corresponding planes of three related pencils or as the locus of the meets of corresponding lines of two related point-stars. If p and q are equal, the two conjugate generations are of the same kind.

Prof. Room's book, in which he uses both synthetic and algebraic methods, is divided into three main sections. Part 1 deals with the general $(|p,q|_r, [n])$ and Part 2 with the loci obtained by specializing the matrix (x_{ij}), with particular consideration of the cases in which this matrix is symmetric or skew-symmetric. Part 3 is an exhaustive and fascinating account of the different types of determinantal quartic primal and associated loci in [4].

The general theorems proved in the first two parts are of a formidable nature, but they a freely illustrated by examples in which the alg braic quantities are given particular numeric values. The author recognizes that it is general the special cases which are of the greatest intere and, while sympathizing with his evident desire keep the book to reasonable proportions, we shou have liked to see him develop some of them furthe

In the generation of the cubic surface in [3] b three related point-stars, there are six sets of thr corresponding planes which meet in a line inste of a point. These six lines and six others, whic arise from the conjugate generation and are paire with these, form a *double-six* of lines, with t property that no two lines of the same set of s intersect and each line of one set meets all b one of the lines of the other. The remainir fifteen lines of the cubic surface arise naturall though not so simply as this, from the projecti generation. In chapters iv and xiii, Prof. Roo describes many new such configurations of line spaces with remarkable intersection properties.

The class of determinantal loci is very extensiv It includes, for example, all plane algebraic curve and, in fact, as the author claims, almost all lo of whose projective properties anything is know are either determinantal loci or closely connecte with them. The great diversity of the problem solved and the naturalness with which they fa into the author's scheme fully justify that clai The book consists very largely of origin researches, and among these the chapters on th representation of spaces by points and the chapt and appendix on the freedom of loci are pa ticularly interesting.

The index and table of contents are admirabl complete and the author suggests a useful cour of selective reading. D. W. B.

X-RAY ANALYSIS AND THE STRUCTURE OF MATTER*

BY SIR WILLIAM BRAGG, O.M., K.B.E., PRES.R.S.

WHEN the new methods of X-ray analysis were first introduced a quarter of a century o, there was naturally no clear realization of the tent and character of the fields of research in iich they would eventually be employed. Certain plications were found for them at once, but the ars have brought wide and unexpected develop-ents. Some of these are gathering themselves gether, and, in conjunction with other methods physics and chemistry, begin to form what ight well be called a new branch of science.

In the early phase of the X-ray crystal studies, e object of interest was the perfect crystal; in e later phase, attention is directed towards the partures from perfection, which turn out to be the greatest interest and importance.

EARLY WORK ON CRYSTAL STRUCTURE

It will be remembered that the method of alysis of the structure of matter by means of -rays was based upon a suggestion made by Dr. . von Laue. If the atoms in a crystal were in gular array, the passage of ether waves through e crystal should be accompanied by diffraction ects, provided that the lengths of the waves were the same order of magnitude as the spacings of e atoms. In the case of the ether waves emitted an X-ray bulb—if indeed the X-rays were her waves, of which there was some doubt at the ne—there were reasons to suppose that the ave-lengths were of the magnitude required. ie experiment was made, and was successful.

The diffraction effects provided means whereby e crystalline arrangements could be calculated. ie researches of the first few years of X-ray alysis were therefore concerned with the aracter of the crystalline arrangement in a umber of the simpler cases. As confidence grew d skill increased, more difficult structures were tacked, and indeed it has been very surprising find what complicated structures can be unvelled. One helpful circumstance has been the istence of families of substances, since the pro-essive differences in the members of a family ve rise to corresponding changes in the diffrac-n patterns. Thus, for example, the large family silicates was examined and the connexions tween composition and diffraction effects, and again between the latter and structure, were observed and compared. Certain simplicities and uniformities then appeared, and it became possible to put in order a mass of details which had not previously appeared to have any relation with each other.

It was not long before the results in this field of research became so numerous that books of no small size were required to contain them. In thousands of cases, the dimensions of the unit cell of the crystal were determined, and at least the space group or character of the arrangement of the atoms within the cell. In a number of these cases the exact relative positions of the atoms could be found, though this additional task has often been formidable. Work of this kind continues, and rightly so, to be the occupation of many investigators. All such work belongs to the first phase to which I have referred.

IMPERFECTIONS OF CRYSTALS

The application of the X-ray methods has for some time been entering on a second phase. It now deals with a natural phenomenon differing entirely from that which was the first to be examined. The earlier work was concerned with the arrangement of the atoms in a perfect crystal, that is to say, a body in which the mutual forces are balanced, and the arrangement is complete. Thermal movements may still be there, but the average dispositions of the atoms are settled, and are uniform throughout the body of the crystal.

It is doubtful whether there is such a thing as a perfect crystal large enough to be handled; perhaps the crystals of diamond and graphite are nearest to perfection. In almost all cases there are deviations from complete uniformity. A crystal that has every appearance of being perfect may consist of an assemblage of minute crystallites, more nearly perfect individually but lacking uniformity of orientation to a greater or less degree. Other bodies that do not appear to be crystalline at all may consist of crystallites oriented so irregularly that the bodies seem to be isotropic. The crystallites may vary in size as well as in relative orientation. Two or more crystal forms may be present in the same body, so mixed together that only the X-ray methods can make any attempt to disentangle them. Sometimes one greater lattice overrides in a more or less regular fashion a smaller lattice, as a pattern of ploughed fields may override a pattern of furrows. Also a lattice may be distorted by strain. In a substance in the liquid state there may be associations and partial arrangements sufficient to show X-ray diffraction.

---

* From the presidential address to the Royal Society, delivered on vember 30.

Moreover, arrangements and dimensions may vary with time, both in solids and liquids; some forms or extents of arrangement may even disappear, new forms may appear at the expense of the old. Perfection of crystalline arrangement is a goal which is never achieved. In fact the processes of the world are based upon such deviations from perfection, and their continuous modification. If all arrangements of atoms were complete, there would be nothing left but stagnation and the peace of death.

It will be seen, therefore, that a new field of research of extraordinary interest is being opened up. It is in this field that the physicist and chemist, and indeed scientists of every persuasion, must look for explanation of many of the properties of their materials, such as their relations to magnetism and electricity, thermal conductivity, tensile strength, various surface effects and so on; and also the time changes in these properties, such as the creep to which the engineer has to give so much attention. Properties such as these have been called by Orowan and others the 'sensitive' properties, since they depend on the particular state of a body, which state in turn depends largely on the conditions of the new field of which I am speaking. The biologist finds interest in it, because the life processes seem to involve the relations between large aggregates, molecules or assemblages of molecules, with one another or with media in which they are imbedded. Somewhere in this field life and matter are first found in association.

It may seem unreasonable to expect help in the resolution of such complications from the X-ray diffraction effects. It is to be remembered, however, that the X-ray photographs are very rich in information. The gratings are three-dimensional and may be examined from a variety of aspects; each photograph or spectrometer record is a two-dimensional diagram of positions and intensities of diffracted spots. A light spectrum of the ordinary kind is uni-dimensional only. The photographs vary in definition, being less easy to read as they deal with more complicated cases; but the technique is rapidly improving.

MOSAIC EFFECT

The earliest of these phenomena of the larger field was the so-called mosaic effect. A crystal of rocksalt, for example, is a mass of small cryste each of which approaches to regularity far m completely than the whole. The separate cryst lites are not in perfect alignment with each oth Hence arose one of the perplexities of the ea days. It was extraordinary to find that the l perfect crystal reflected the X-rays in grea intensity than the more perfect, and that t reflections from the face of a crystal—quartz, example—might be increased if the surface w roughened. The puzzle is solved if we remem that, as Darwin and others pointed out, o crystallite may screen another. If the orientati of the two are exactly the same, and they are at the proper angle for reflecting the incide X-rays, the first crystallite will partly absorb t rays in producing its own reflection and the low will not have its full opportunity. But if, as usual, the crystal is moved through small ang about the above setting so as to give every cryst lite its chance—provided that the X-rays c penetrate the crystal so far as to reach it—and the second is in the right orientation for refle tion when the first is not, then the incident ra get through the first and are reflected by t second; the integration of all effects theref gives a larger total when the crystallites are r parallel.

This mosaic character is very common, even crystals of the purest material. There are indi tions, as remarked by Goetz and others, that some cases at least it is the state of grea equilibrium. Thus W. A. Wood shows th crystals of copper and other metals of extre purity are reduced by cold working to crystalli in more or less complete disarray. The substan do not then return to their former state, thou they can be taken some way towards it by moder heating. To restore them to their original state would be necessary to begin over again from t melt. A similar effect was shown by Ewald occur in the case of rocksalt. It may also significant that of the two forms of diamo examined by Robertson and Fox, that which the more transparent to infra-red and ultra-viol and may therefore be taken to be in grea internal equilibrium, is also the one in whi there is some mosaic character.

If this form of disintegration of a larger crys into crystallites is really due to the release energy, it might be expected to proceed until t process was complete and the substance beca amorphous. Wood shows that it does not proce indefinitely and that the copper crystallites ha an average linear dimension of about 700 A.; silver the figure is 800, for nickel 1200, and so c The disintegration ceases at a certain point. T metals were of extreme purity. Unless it appe at the mere trace of impurity governs the effect, must be supposed that the disposition to form ggregates of definite magnitude is present in the pper atoms themselves.

The presence of crystallites of a definite pattern, eir dimensions, their preference for any particular ientation in relation to the body which contains em and their proportional amounts are all etermined by the X-ray photographs. It is to e remembered that the diffraction spectra of a mpound of different crystallites do not modify disturb each other's evidence. The data on hich calculations are based are the forms and tensities of the spots and lines in the X-ray otographs. The calculations are often difficult d lengthy because so many factors have to be ken into consideration ; in fact there is plenty evidence, and the most troublesome part of the siness is its interpretation.

APPLICATIONS TO METALS AND TO LARGE MOLECULES

It will be readily understood that such measure- ents as these can be of great assistance in the udy of metals. It is possible to examine in a new d most effective way the phase diagrams of the etallurgist, and the various effects of composition, mperature and time, and this not only for binary loys but also for ternary and still more compli- ted mixtures. With these powers in hand, and ith the remarkable accuracy of the modern -ray spectrometer, which can show minute anges of form due to temperature or an admix- re of foreign atoms, and can show also any varia- ons in the extent of order and disorder in the omic arrangements, it is not surprising that eoretical metallurgy has acquired a new life d that practical metallurgy begins to gain ereby.

Since the X-ray methods can do so much to scover the composition of molecules, even very rge molecules such as the phthalocyanines obertson) or the sterols (Bernal, Crowfoot and hers), and also to determine the arrangement of e molecules in crystalline aggregates, and yet rther to find any preferred orientations that ere may be, the methods can be fitly used for e examination of fibrous materials. In cotton, lk, rubber and many other substances there are ng-chain molecules which are linked together into ystallites having preferred orientations along the ngth of the fibre. So also nerve, muscle, horn d such-like contain proteins and keratins in rous forms. It is even possible, as Bernal has own, to find some details of the composition, ructure and arrangement of immense molecules ch as those of a virus. Very interesting papers on these subjects have been communicated to the Royal Society, some of them during the present year.

It is to be observed that the extension of the X-ray methods to these larger scale problems is greatly facilitated by extrapolation from simpler observations. In the case of organic substances, the modes of assemblage into characteristic combinations of atoms, such as the association of carbon atoms in the benzene ring, are governed by rules which are so closely followed in the simpler cases that they can be assumed to hold in the more complicated. These rules relate to the distance from atom to atom in various cases, and the mutual orientations of atoms. In this way very important suggestions have been made in respect to the construction of the more difficult assemblages.

It is to be remembered, of course, that there are other physical methods of observation which contribute to the understanding of the complex substances of Nature, which are all the more efficient now that the X-ray methods are able to make their characteristic contribution. First of all comes chemical science, the power of which is so obvious and well known that I need not do more than refer to it. Optical properties have been found to be extremely useful. So also the magnetic properties are found to be closely related to structure. Thus, for example, the disposition of a molecule containing benzene rings can often be predicted from diamagnetic measurements.

The sum total of these powers, some new, some old, all reinforcing each other in a common advance, is so great that, as I have already said, a new field of inquiry of first-rate importance has been well entered. That which the eye can see is one thing : that which the microscope reveals is another. Far beyond any vision is the individual atom and the atomic nucleus, of which so much has been discovered in recent years. But a vast range of magnitudes lying approximately between 10 and 10,000 A. has never been accessible to the direct attack which the ranges on either side of it have experienced. Within this range lie all the processes which are concerned in the building of living substances, animal and plant, and in the changes of growth and decay. In this range lie also elements that are the origin of the properties of our materials, alloys, glasses, fibrous substances of all kinds, and here take place transformations which change these properties, some of them especially rapidly when urged by heat, some so slowly that centuries must pass before they become visible or effective. The recent advance into this new field is only the preliminary to what is sure to follow. We have before us an inquiry of supreme interest.

CAMBRIDGE UNIVERSITY EXPEDITION TO JAMAICA

BY DR. V. J. CHAPMAN,
UNIVERSITY OF CAMBRIDGE

THE Expedition left England in two parts, on June 15 and 22, and was scheduled to return on September 19. Owing to the outbreak of war, the main party left Kingston a few days earlier than was anticipated, but in spite of this change of plan the principal items in the programme were carried to a successful conclusion. The personnel consisted of Dr. V. J. Chapman, the leader, Dr. H. Hamshaw Thomas, who took charge of the forest party, Mr. J. A. Steers, who took charge of the schooner party on her voyage around the island, Mr. J. S. Colman in charge of the zoology, Mr. W. R. Philipson, Mr. J. Lofthouse the surveyor, Mr. K. R. Sporne, and Mr. D. J. Crisp. We were fortunate in being able to co-opt three persons in Jamaica, and it is a pleasure to record how much their inclusion helped the expedition. The local members were Mr. C. E. Hamshere who assisted the geographers, and Miss O. Baxter and Miss L. Scudamore who aided the forest party. The Expedition was largely financed by the Royal Society, and our thanks are due to that body and other institutions which provided money, and also to the Government departments of Jamaica and private residents in the island whose ready co-operation greatly facilitated our work.

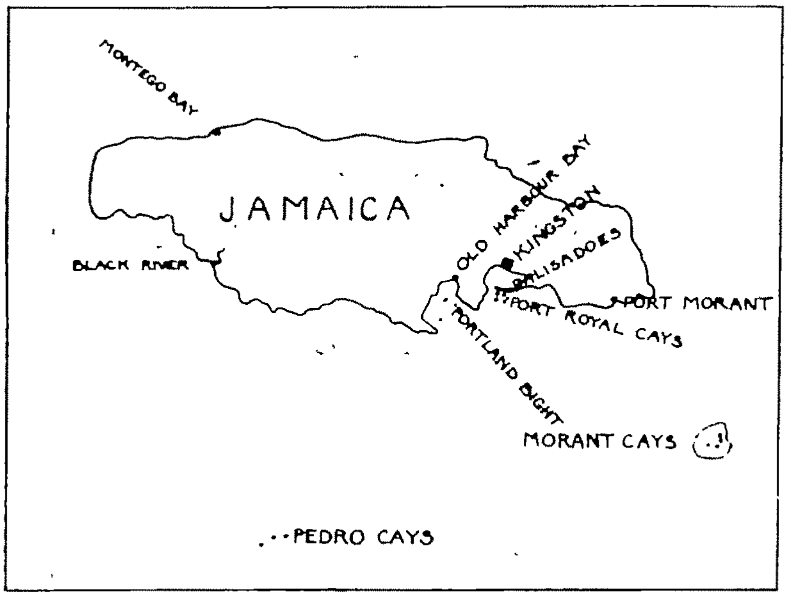

Fig. 1.

The primary object of the expedition was study the development of the cays and of t shore line, especially in the neighbourhood Kingston, and also the role of the plants a animals concerned in the process. A visit w first paid to the Morant cays which lie on a sho about 60 miles south-east of Kingston (see acco panying map, Fig. 1). Whe later on, the cays near Kingst were examined, it became appa ent that the Morant cays for an independent group the stru ture of which is quite unlike th of the Kingston cays. The Mo ant cays, four in number, a simple sand cays composed *Halimeda* and shell sand togeth with coral fragments (Fig. These cays were unique amo those investigated in that th beach rock forms promenad comparable to those of the lo wooded islands of the Gre Barrier Reef. These structur always occur on the windwa sides of the cays and are heavi eroded. In some of the depre sions crystalline salt and alg appeared to be combining to pr duce a hard crust similar to th formed on the surface of the promenade, and it hoped that an analysis of the crust and the alg salt mixture may throw some light on its form tion. Whilst the height of the promenades on th Queensland islands suggested that a slight fall sea-level had occurred, we came to the conclusi that this was not the solution on the Morant cay but that storm waves and spray would probab account for their height.

Of the cays in Portland Bight, all but two a built up largely of *Halimeda* sand, whilst those Port Royal (outside Kingston Harbour) form graded series extending from the outer cays, wi coarse coral on the exposed south-east and sou sides, to the inner sandy cays, with only a fe boulders on their weather sides. The similari of the environment of these two groups of ca makes it very difficult to explain why one set so different from the other. Many of the ca

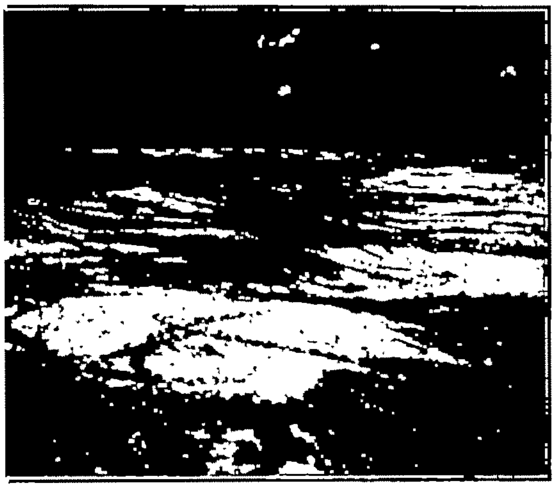

Fig. 2.
Ipomœa and low sand-dunes, South East Cay, Morant Cays.

sees one or more lines of beach rock lying at rying distances off-shore, and it would seem at these represent former outlines of the cays d they might therefore be used to indicate anges of shape. A study of the physiography the Palisadoes, together with what is known of past history, suggests very strongly that this d and shingle spit rests on a rocky ledge, and at it has united several former shoals or cays ich are now represented by the stable salients amb Point, Little Plumb Point, and Rocky int. There are three factors which have con- lled the development of this spit in the past and ich will determine any future change.

(1) Hurricanes. These are capable of opening breaches in the spit and re-isolating the lividual cays.

(2) Earthquakes. These may have the same ect.

(3) Sand and shingle movement from east to st due mainly to wave action. Normally the lutionary work of this last factor predominates, t it has been upset time and again in the past the single or combined effect of the first two.

In other parts of the world where coral reefs are be found, the calcareous red algæ play no incon- erable part in their formation, and hence it was prising to note how insignificant this group of e are in Jamaican waters. It may be said t the cays and reefs of Jamaica are conspicuous the comparative paucity of living coral and careous red algæ, although conditions would pear to be favourable for both. *Halimeda*, in ing rise to a sand, is the only alga which plays real part in shore-line development, but even s genus is not as abundant as might be expected l it seems that its maximum abundance must e been reached in the past. The observation that many of the cays do not appear to occupy greater areas than they have in the past, as revealed by lines of former beach rock, strongly supports the thesis that fresh supplies of *Halimeda* sand are not being produced at a great rate.

The mangroves, of which there are three principal species, *Rhizophora mangle*, *Avicennia nitida* and *Laguncularia racemosa*, form the principal vegetation which is concerned with shore line development in this part of the world. They are completely absent from the Morant cays, and this can probably be explained by the fact that the dominant winds blow from the south-east and so any seeds would have to travel over a considerable distance in order to reach the cays. With a persistent wind in this quarter, colonization from Jamaica is out of the question even though it is so near. By way of contrast, the cays in Portland Bight and off Port Royal bear all three species. The mangrove vegetation can be divided into three groups: (*a*) reef mangroves with roots in the holes and crevices of the boulders; (*b*) mud mangroves occurring at the mouths of estuaries; and (*c*) sand mangroves growing on the sand cays and sand spits. Those in group (*a*) play no part in the

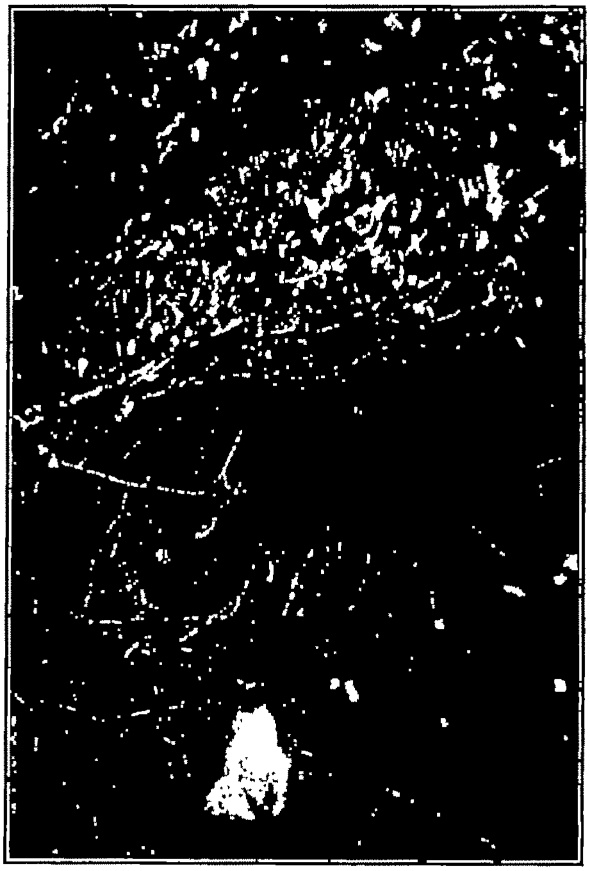

Fig. 3.
Pneumatophores of *Avicennia nitida*.

formation of new land, but those in group (*c*) may spread and unite several small sand cays or ridges and so produce one large swamp. This has undoubtedly occurred along the inner edge of the Palisadoes and is taking place to-day in the Bogue islands near Montego Bay.

As the tidal range in Jamaica is very small, any zonation of the different mangroves is not easy to distinguish. In protected bays, on the leeward side of cays, and along rivers, *Rhizophora* forms a narrow outer fringe with *Avicennia* behind, whilst *Laguncularia* tends to mix in with the *Avicennia* when the ground becomes slightly higher and drier. In exposed sand-spit areas, however, *Laguncularia* forms the outer fringe with *Avicennia* behind, whilst *Rhizophora* is confined to the damper pools and depressions. Ultimately the mangrove vegetation yields to dune, salina, or freshwater swamp, depending on the local conditions. The most active production of new land by mangroves is taking place at the mouths of rivers, but even in some of these localities exposure to wave action has occasionally brought about an onset of erosion. In such places old mangroves lie uprooted in front of the protecting ridge, whilst seedlings never have an opportunity to establish themselves. In other places where there is very little mud or sand deposition the mangroves produce a marine peat, but it is evident that the formation of new land by this method must take an extremely long time; in the end it results in a much more solid substrate than is normally associated with mangroves.

Particular attention was paid to the ecology of *Avicennia nitida* and the functions of its pneumatophores (Fig. 3). The tides around Jamaica permit of one major (nine inches to one foot) and one minor (three to five inches) tide a day, and observations showed that only the major tide covered the soil in much of the swamps. In addition to this diurnal fluctuation there were the spring tidal cycles, and it was evident that in some of the swamps quite a number of days could elapse between two floodings. It was also established that *Avicennia* grew on three distinct types of soil: (*a*) sandy soil; (*b*) muddy soil; (*c*) peat. The oxygen content of the soil water was very low, ranging from 0 to 0·26 per cent, and although bubbles of gas could be obtained from most positions within a swamp, upon analysis such gas always yielded a low oxygen value, the average being about 7 to 8 per cent. This is very different from the concentration in the atmosphere, and it is probably insufficient for the respiratory metabolism of the lateral roots. Analyses of the gas contained in the pneumatophores and lateral roots showed that it was not very different from that of the atmosphere so far as the oxygen
carbon dioxide content were concerned. T
means that the pneumatophores must form
channel for gaseous interchange. Whenever pa
of the pneumatophores were below the soil s
face they bore slender horizontal rootlets at
depth of about 1 cm. If, however, the whole
the pneumatophore was exposed, as, for examp
when the lateral roots crept among the bould
or were exposed upon the beach, the horizon
rootlets would be absent or else growing
directly from the lateral roots. These are eviden
the absorbing organs, and normally they deve
from the pneumatophores. Some evidence
also obtained to show that, whilst not prima
organs of respiration, nevertheless the pneuma
phores do exhibit some respiratory activity.

The zoologists, Mr. Colman and Mr. Crisp, sp
most of their time collecting for the British Museu
one of the more interesting finds being *Littor*
minima, of which only three specimens h
previously been known. Three level-traver
were made across well-vegetated beach-rock a
from one of these, which exhibited excellent al
zonation, samples of the flora were also taken.
tide gauge was established at Port Royal and fr
the records obtained it is hoped to secure so
data about the relative positions of the differ
animals and plants in relation to tide-lev
T. A. Stephenson and his school have shown th
on the South African coast, where the tidal ra
is comparable to that at Plymouth, systematica
related animals tend to occupy the same e
logical positions as at Plymouth. It theref
seemed worth while to compare with these t
places the corresponding distribution in the Car
bean where the range of tide is very small.
soon became evident that there is, on the wh
a remarkable paucity of living coral around
cays, especially the Morant cays, and this
striking because in similar places off the Quee
land coast masses of coral would be encounter
At present there seems to be no adequate ex
nation of this feature, but it is clear that the c
and reefs are not coral in any full sense of
term. The general conclusion is that the Jamai
marine fauna, though varied, is, neverthele
somewhat scanty.

Very little can be recorded about the activit
of the forest party because the collections, wh
have been left in Jamaica for safety, have yet
be examined. Dr. Thomas collected much mate
of the monotypic genus *Rhipidopteris peltata* a
also of the genus *Elaphoglossum*, both of wh
are imperfectly known. Messrs. Philipson a
Sporne, apart from collecting for their own p
poses, secured a collection of wood specimens
the Imperial Bureau of Forestry at Oxford.

TREE RINGS AND CULTURES IN THE SOUTH-WESTERN UNITED STATES

ENDROLOGICAL evidence, in other words the tree-ring method of dating as applied the archæological investigation of early cultural mains in the south-western United States, not ly confirms, and is itself confirmed by, strati- phical evidence, but also serves to afford a clue at least one among the causes which may have ntributed to bringing about fundamental changes mode of life of south-western peoples, and even e decay of a flourishing civilization. It has, for ample, long been an open question among nerican archæologists why a people living in all scattered villages should develop a tendency concentrate in urban communities, which er become the great communal houses of the eblo period; and further, why this Pueblo ilization, on attaining a remarkable peak-point development, should suffer a serious decline, d many settlements be abandoned. At neither int does there appear to be any significant ctuation in numbers of the population, nor y serious increase in raiding activity of hostile bes.

It is pointed out by Dr. F. H. H. Roberts, jun.[1], a survey of current archæological knowledge of e south-west, that both these crises coincide th periods of drought indicated by the tree-ring quence, while the period of greatest expansion Pueblo civilization is also a twenty-year period favourable conditions.

In introducing this report on his archæological vestigations in eastern Arizona, Dr. Roberts vances arguments for a new classification and menclature in south-western archæology, to persede that adopted at a conference held at cos in 1927. It was then decided to accept a crimination in the Basket Maker culture, at that ne the earliest differentiated in the south-west, to three stages, and of the Pueblo cultures into e, of which the latest stages were post-Columbian d extended to modern times. Yet, as Dr. oberts points out, Basket Maker I, the primary age of a simple nomadic hunting people, leading to the semi-hunting, semi-agricultural phase the later Basket Maker culture, is entirely pothetical, and no relics which can be assigned it have been discovered. Hence he suggests its imination, and the substitution of 'Basket Maker' nply for the second stage, the earliest known present, and 'Developed Basket Maker' for age III. Pueblo I and II become 'Developmental eblo', while Pueblo III–V are covered by Great Pueblo, the period of greatest expansion, 'Regressive Pueblo', the period of decline, 'Renaissance Pueblo' and 'Historic Pueblo', as more truly in consonance with the history of the development of the culture.

Further, in considering the character of the earliest period, Dr. Roberts distinguishes three types of culture—two major provinces, to which he now adds a third. Of these the first centres in the plateau country of the area comprised in the States of New Mexico, Arizona, south-west Colorado, Utah, eastern Nevada, western Texas, and northern Mexico. For this the name 'Anasazi' is proposed. The second is the culture of the desert precincts and lowlands, to which the name 'Hohokam' is applied, while a third province, hitherto considered a variant of Anasazi, is the 'Mogollon', which centres in San Francisco and the Mimbres River valley in south-west New Mexico.

The main differences between the Anasazi and Hohokam cultures summarily stated are as follows: While the Hohokam practised cremation, the Anasazi buried their dead. The Hohokam built rectangular, single-unit houses of pole, brush, and plaster construction, while the Anasazi progressed from circular, or rectangular, single-unit dwellings of poles, brush, and plaster to multi-storied communal houses of stone. The Hohokam progressed from flood-water irrigation to an extensive canal system for watering their crops; but the Anasazi depended mainly on flood-water, though in some sections they employed small ditches. Both used coiled pottery, but their finishing processes differed, as did the decoration, the Anasazi developing from black to polychrome, while the Hohokam used red on buff.

The Mogollon cultural pattern is that of a sedentary agricultural-hunting complex, in which the hunting aspect is more pronounced than in either Anasazi or Hohokam. As a rule, the dead were buried, but there was some cremation. Houses were rounded and semi-subterranean, followed by rectangular semi-subterranean, and then by the Pueblo type.

While dendrological evidence is available for dating the Anasazi culture, the varieties of timber used in house construction in the Hohokam culture is not adaptable to tree-ring studies; and the determination of period in Hohokam must depend upon pottery types and reference to trade objects of the Anasazi penetration until A.D. 1000, when

Anasazi settlement took place in the Hohokam province. Timbers from the Mogollon houses have been dated, making correlation with Anasazi possible. It is suggested that basic Mogollon, not yet clearly defined, was contemporary with Modified Basket Maker, and its later stages of development with Developmental Pueblo, Great Pueblo, and Renaissance.

Investigation of the relations of the Mogollon culture to various phases of Anasazi, both Bas Maker and Pueblo, have been in progress throu out the summer of 1939: at Glenwood, New Mex (Field Museum of Natural History, Chicag a second expedition working also near Glenwc (Logan Museum); and on a village site occup A.D. 700–800, south of Showlow, Arizona (Ariz State Museum).

OBITUARIES

Prof. H. H. Meyer

THE death of Hans Horst Meyer on October 6 severs perhaps the last direct link with the beginnings of experimental pharmacology as a separate science.

Meyer was born on March 17, 1853, in Insterburg in East Prussia, and studied medicine at Konigsberg, Leipzig and Berlin. A story goes that he passed his qualifying examination in all subjects except pharmacology and that it was to rectify this defect that he undertook an investigation under Jaffe, which gave him an introduction to the technique and literature of experimental physiology. Later he went to Strassburg to work under Schmiedeberg, as did nearly all the prospective pharmacologists of the time, and had just been appointed assistant to Schmiedeberg when he was called to Dorpat in 1881. Here he succeeded Boehm, the immediate successor of Buchheim, who had established in Dorpat the first laboratory for experimental pharmacology. In 1884 he became professor at Marburg where he worked for twenty years, after which, in 1904, he became director of the Pharmacological Institute in Vienna. He held this appointment for another twenty years, retiring in 1924. Still active, he was put in charge of a department for standardization of drugs, an appointment to which there was no age-limit and accommodation for which was given in his old laboratory. Up to a year or two ago, he still held every month in his own house a discussion on some pharmacological problem, which all the workers in the Pharmacological Institute, including his successor Pick, attended, and I am informed by one of the staff that up to the end Meyer took a leading part in these discussions, with little impairment of his enthusiasm or of the constructive and critical acuity of his mind.

Like most of the pharmacologists of his time, Meyer was no narrow specialist. His investigations ranged over a wide field, and behind it all was the desire to link up pharmacology with general biology and pathology on one hand and the treatment of disease on the other, towards the establishment of a more rational therapy. His influence is to be measured not only by his achievement but also by the vision which prompted it and by his guiding example of the lines upon which pharmacological investigation could be profitably pursued. Among the phar acological problems he investigated were the acti of the alkaloids of jaborandi and corydalis, ac poisoning with phosphorus and with metals, especia iron and bismuth, and the action of purgatives a astringents. He also did some pioneer work on t reaction of the blood, on heat-regulation and on t action of diuretics and, resulting perhaps from early work on jaborandi, he was especially interest in the development of the knowledge of the autonom nervous system.

Meyer's claim to a permanent place in the histo of pharmacology will, however, probably rest up his contributions to two problems which lay outsi the range of routine descriptive pharmacology. T first of these was his theory of the action of narcotic he sought to explain their action by their relative greater solubility in lipoids than in water, which l to their accumulation in the cells of the central nervo system with a consequent suspension of nervo activity.

This theory, which was independently and alm simultaneously suggested by Overton, has requir subsequent modification, but its importance lies its being a pioneer attempt, based upon experiment evidence, to solve one of the fundamental proble of pharmacology—the chemical or physical basis f the site and quality of pharmacological action. T other problem to which he introduced new co ceptions was the action of bacterial toxins. Especial will be remembered his suggestion that tetanus tox travels to the central nervous system by way of th motor nerves rather than by the blood stream. I also showed that antitoxins were the more effecti the earlier they were given, and were relative inefficaceous once the toxin had combined with t tissues.

Apart from his own work, Meyer profound influenced, by his wide knowledge and imaginati power, those who went to work with him fro different parts of the world. His scientific eminen was recognized by many universities and learne societies outside his own country. He was the seni surviving honorary fellow of the British Physiologic Society and, with J. J. Abel, was the first honora member of the British Pharmacological Society.

J. A. GUNN.

Dr. E. P. Poulton

EDWARD PALMER POULTON, who died on October , was the eldest son of Sir Edward Poulton. He s born at Oxford in 1883, and educated at the agon School, Oxford, and at Rugby; in 1902 he tained the Brackenbury Scholarship in natural ence at Balliol College, Oxford. After taking the st M.B. he read Chemistry Finals.

Poulton went to Guy's Hospital for his clinical rk in 1907 and qualified B.M. (Oxon.) in 1910. ter appointment as house physician, he won the dcliffe Travelling Fellowship and worked in rmany. His early scientific work (1912–14) was stly on the metabolism of uric acid and of creatin d creatinin.

In 1914 Poulton was appointed assistant physician Guy's Hospital, and he became interested in the mical side of diabetes, working on the value of eolar air determinations as a measure of the dosis and also writing on the value of starvation the treatment of diabetes. The introduction of ulin in 1922 intensified his interest in diabetes, and main clinical work continued to be with diabetic tients.

In 1920 he was elected to a Beit Memorial Research lowship. At an early stage he had worked with ldane on the effects of want of oxygen on respiran, and this influenced the direction of much of his er work. From 1918 until 1925, with a series of pils, Debenham, Joffe, Campbell, Parsons, and er Spurrell and Warner, he was working conually on the problem of dyspnœa in connexion h the oxygen and carbon dioxide carriers in the od, and with its hydrogen ion concentration and h the oxyhæmoglobin curve. For a time at Guy's spital an oxygen chamber was installed where ients could live in an atmosphere of, say, 40 per t oxygen, and the influence of this on their ease and on their physiological processes could be served. He was satisfied that many patients with onic bronchitis and heart disease obtained benefit m this treatment, and this was the foundation of belief in oxygen therapy which became the main erest of his later years.

nother early interest to which Poulton returned ain was the problems of pain in gastric ulcer l of pain and of normal sensation in the œsophagus. carried out investigations on himself and others introducing into the œsophagus a balloon which ld be distended while the subject was under ray examination. In 1928 he gave the Oliver-arpey Lectures, dealing with the experimental dy of certain visceral sensations, and the next r published a paper in the *Guy's Hospital Reports* the physiological considerations underlying abninal pain.

The mechanical side of any investigation always de a great appeal to Poulton, and much of his er work was concerned with the development of aratus, for example, positive pressure machines l oxygen tents. Although often rather complicated appearance, his oxygen tent in its final form was neat and beautiful piece of apparatus. His enthusiasm for oxygen therapy has no doubt been one of the factors leading to the increased use of this treatment; latterly his enthusiasm led him to start experimental observations on patients with such diverse conditions as rheumatic carditis and cerebral hæmorrhage.

Apart from the many published papers on the subjects mentioned, Poulton published two books, "Oxygen and Carbon Dioxide Therapy" with Argyll Campbell, and "Diets and Recipes and Treatment of Diabetes and Obesity". He also acted as editor of the 12th to 14th editions of "Taylor's Practice of Medicine", the first of these in 1922. This was perhaps his greatest contribution to medical teaching; he devoted much time and trouble to the preparation of each edition, so that this old text-book was made a good practical guide and kept remarkably up to date.

Poulton was chairman of the International Society of Medical Hydrology, and in 1937 was president of Section I (Physiology) of the British Association—an unusual distinction for a practising physician. He was also greatly interested in the work of the League of Nations Union and spent much time on this.

There were many qualities, including his whole-hearted enthusiasm and his charm and kindliness, which endeared him to his many friends. Although he knew his heart was affected, his regular hospital duties and teaching, his research work and writing, and his many societies and meetings, show how little he let this stand in the way, and in their multifarious activities he never spared himself.

In 1911 Poulton had married Elfrida, youngest daughter of Mr. Charles Maclean of Glenearn, Perthshire, and had three sons and two daughters. His eldest son has recently qualified and is now a medical officer at Pembury, the second is in the Army, and the third a medical student. M. CAMPBELL.

Major A. E. Levin

WE regret to announce the death of Major Arthur Everard Levin, which took place on November 8 after a short illness. Levin was born on February 17, 1872, and was educated privately. He took up electrical engineering as a profession and enlisted in the Royal Engineers on the outbreak of the South African War. For some time after the conclusion of that war he held a Government appointment and later was associated with the firm of Mordey and Dawbarn, consulting electrical engineers, retiring from his profession in 1928. He remained with the old 'Volunteers' when they became 'Territorials' and was called up for service on August 5, 1914. Later he was placed in command of the first Electrical and Mechanical Company to be sent to France, and was mentioned in dispatches in April 1918. He saw service in Italy in the same year.

After demobilization, Levin's interests turned to astronomy. In 1919 he was elected a member of the British Astronomical Association and in 1921 a fellow of the Royal Astronomical Society. His work in astronomy was mainly connected with computations.

He was the second director of the Computing Section of the British Astronomical Association, formed in the 1920–21 session, a position which he held with only one or two minor interruptions until 1938. The annual production of the "Handbook" required much time and patience, especially with computers who had to be initiated into the subtleties of the calculations essential for the work. Levin displayed a wonderful amount of tact and judgment in teaching new computers, and his unfailing courtesy and kindness will never be forgotten by those who could always turn to him for advice and guidance.

The "Handbook" is used at many of the great observatories for the information that it supplies on various branches, not least that dealing with the ephemerides of comets, for which the perturbations by the major planets have been computed. In this connexion reference may be made to the last great computational work that Levin undertook, in collaboration with Mr. J. G. Porter, his successor as director of the Computing Section. This was the computation of the perturbations of the planets on Comet Pons-Winnecke for two revolutions, Cowell's method being used for the greater portion of the work. The comet was found almost exactly in its predicted position by van Biesbroeck, an indication of the accuracy of the calculations. Levin made a speciality of the mutual eclipses and occultations of Jupiter's satellites, and a full description of his method of prediction appeared in the *Memoirs of the British Astronomical Association*, 30, 3, December 1934. He was elected president of the Association for the sessions 1930–32 and proved himself a very popular and efficient officer.

It is characteristic of Levin's love for astronomy that he presented his 4-inch refractor to the Association this year, and he has also left all his astronomical books and his 6-inch telescope and observatory, now at Selsey, to the Association. He leaves a widow and one son, the latter serving in the Navy.

Dr. G. D. Lander

GEORGE DRUCE LANDER, who died on October 25, aged sixty-five, was a man with a strong personality and a chemist whose work was characterized by breadth of outlook and soundness of judgment.

Lander studied chemistry at the Royal College of Science and Birkbeck Institution, London. After working with Japp in Aberdeen on the synthesis of pentacarbon rings, he proceeded to St. Andrews, where he assisted Purdie in his researches in stereochemistry. Purdie and Lander observed that the product obtained by the action of ethyl iodide on the silver salt of optically active lactic acid possessed a higher rotation than ethyl lactate prepared by the usual esterification process, and they suspected that the higher value was due to the presence of a small amount of the ethoxy derivative. This and similar observations led Purdie and his associates to devise the silver oxide – alkyl iodide method of alkylation, a reaction which afterwards proved to be the most serviceable tool in the hands of organic chemists
the St. Andrews and Birmingham Schools for t
controlled degradation of carbohydrates. At Univ
sity College, Nottingham, Lander made a study
the chemistry of imino-ethers, and in 1903 he v
appointed to the chair of chemistry and toxicolc
at the Royal Veterinary College, London.

In order to deal satisfactorily with the increasi
number of cases of suspected poisoning amo
animals on which he was consulted, Lander found
necessary to make a comprehensive experimen
survey of the methods for the detection of mine
and other poisons. Some results of this work w
published in communications to the *Analyst*. C
cumstances also arose which led him to investig
the separation and identification of very mini
amounts of alkaloidal drugs, and a short pa
entitled "Microanalysis of Alkaloids" was aft
wards published in the *Analyst*. His skill in manipu
tion contributed to his success in this field, in wh
he was actively interested for the remainder of
life.

Lander retired from the Royal Veterinary Coll
in 1920. The well-known "Systematic Inorga
Chemistry" by Caven and Lander was published
1906, and Lander's "Veterinary Toxicology" in 19
Lander was a member of the Court of Governors
Birkbeck College for some years, and an exami
in chemistry and toxicology for the Royal College
Veterinary Surgeons from 1923 until 1939. After
retirement from teaching he resided at Tenterd
Kent, and devoted much time to the municipal aff
of that ancient borough. He leaves a widow, w
gave him much assistance in his analytical work

G. W. CLOUGH

WE regret to announce the following deaths:

Dr. William H. Brown, lecturer in botany in
Johns Hopkins University, formerly director of
Bureau of Science at Manila, on November 9, a
fifty-five years.

Dr. Livingston Farrand, emeritus president
Cornell University, formerly professor of anthropol
in Columbia University, on November 8, a
seventy-two years.

Prof. E. A. Gardner, emeritus professor of classi
archæology in the University of London, on Novem
27, aged seventy-seven years.

Prof. Waldemar Lindgren, formerly professor
geology in the Massachusetts Institute of Technolo
on November 3, aged seventy-nine years.

Prof. F. K. Richtmyer, professor of physics
Cornell University, on November 7, aged fifty-ei
years.

Mr. A. A. Simpson, C.M.G., C.B.E., president
the Royal Geographical Society of Australasia,
known for his explorations in Australia, on Novem
27, aged sixty-four years.

Prof. Charles Vaillant, formerly director of
X-Ray Departments in the Baudeloque Clinic
the Lariboisière Hospital, one of the most emin
X-ray pioneers, on December 4, aged seventy-se
years.

NEWS AND VIEWS

ience and Censorship

THE so-called magnetic mine and the device ently used by Germany for laying mines at sea means of aircraft are reminders—if such reminders e necessary—of the increasing use which is being ade in warfare of recent research and invention. is must not be placed either to the credit or debit le of the balance sheet of science. Very few indeed the scientific developments now being widely used the present war are the outcome of research rected towards their present purposes; rather they e adaptations of results obtained by men of science their inquiries into natural phenomena, and many them have a history of much useful service to ankind before their powers for destruction were ilized. Scientific curiosity, the urge to know how d why things work, must never be stifled; and time of war, this is especially true. It is all the ore regrettable, therefore, that the powers that be glect to release information which would satisfy e curiosity of scientific workers. Speculative ticles in the lay press carry little conviction; it ould not be unduly difficult to keep men of science formed of the general principles of so-called new eapons without giving information to the enemy; is would do much towards allaying the doubts oused by official silence. As was pointed out in e leading article in NATURE of October 14: "In e fighting services themselves the methods of fence and offence are largely scientific. Some of ese methods are highly secret; others are well own to the enemy. There could be no conceivable rm, and there might be great good, in informing e public freely of the latter. . . . The present nger is that everything scientific may be censored, en laws of Nature." Publication of scientific facts ready well known to the enemy—for example, the ructure of various of his own instruments captured action or otherwise recovered—would prove not erely of interest to men of science but also probably the utmost value in forming the topic of scientific scussion.

ıvasion of Finland

EARLY this year, Czechoslovakia was lost to mocracy by the action of Germany; last September, Poland was invaded and very shortly afterards divided between Germany and the U.S.S.R. ow Finland has been attacked by the U.S.S.R. he methods adopted by the aggressors, German and ussian, have been similar in each case. These two ictatorships are making a determined onslaught on naller and independent States, and all who value eedom of thought and other democratic institutions ill regard their actions with abhorrence. Finland, as separate State, is young in years, but her people ave already established for themselves a reputation r enterprise and industry. A considerable export ade in timber, wood-pulp and butter has been built up, and the country also possesses valuable nickel deposits which were being developed. Helsinki, the capital, has an ancient university and a technical institution. Readers of NATURE will recall several communications in these columns from Prof. A. I. Virtanen and colleagues, of the Biochemical Institute, Helsinki, describing work on chemical aspects of the biological fixation of nitrogen, while Dr. P. Suomalainen has recorded work on changes in the blood which occur in hibernating animals. It is also of interest to note that M. Pekkala, finance minister in the new Government formed immediately after the invasion of Finland, is director of the State Forest Institute.

Science and Political Theory under the Soviets

A LITTLE while ago archæologists and students of the prehistory of the Eurasiatic continental tract received with profound regret and no little dismay the news that no further numbers of *Eurasia Septentrionalis Antiqua* would be published. This much-valued archæological periodical has been issued under the auspices of the Finnish Archæological Society and edited by A. M. Tallgren, professor of archæology in the University of Helsinki. Founded by Prof. Tallgren himself, it has contained in the twelve volumes of its issue many notable contributions to archæological science in its special field, the prehistory of European and Asiatic Russia and adjacent regions, by archæologists of world-wide reputation; but its mainstay has been the work of its editor, Prof. Tallgren himself, who has devoted more than thirty years to this subject. It was his constant aim, however, to advance knowledge in this field by synthetic study of the broader problems, rather than by specialized research; and for this purpose it has been necessary for him to seek international co-operation both by way of comparative study and for constant reference to, and verification from, original material in museums and collections. This assistance has been given freely. Prof. Tallgren modestly attributes the success of *Eurasia* to the collaboration of more than a hundred archæologists in Europe and the United States. He personally, for his own special studies, has relied to no little degree upon the help of his Russian colleagues; but for some time past he has received no periodicals from Russia, and his letters and inquiries addressed to Russian archæologists have remained unanswered. The failure of this essential source of information and the absence of collaboration from this field of investigation leave so many gaps and uncertainties in Prof. Tallgren's studies that with profound reluctance he has come to the conclusion that his work, and with it the publication of *Eurasia*, must come to an end.

IN making this announcement, Prof. Tallgren does no more than glance at underlying causes when he refers to the possibility of harming an individual in his own country even by commendation. Under the Soviets, the imposition of Marxist doctrine on archæological theory has constrained research workers, members of the staffs of archæological museums, and teachers in universities and higher schools to subscribe to a particular theory of cultural development, in which emphasis is laid on economics to the exclusion of all other influences bearing on the development of peoples. The enforcement of this political doctrine on scientific teaching and research has fixed a gulf between the Russian archæologist and his Western colleagues, and the Soviet political dictatorship is evidently determined that it shall be completely effective against Western archæological thought, which in taking a broader view is accused of interest only in the study of the exploiters of the proletariat. Hence the Russian archæologist must be guarded against the views of those who, for example, attach weight to the influence of migration. Those who do not conform implicitly to this frustration and perversion of the spirit of science and the aim of research, or such variation of it as may occur to Soviet rulers from time to time, have been removed from the performance of their duties, while some have vanished, leaving no trace.

Prof. D. H. Campbell

ON December 16, Prof. Douglas H. Campbell, emeritus professor of botany in Stanford University, California, will attain his eightieth birthday. His repeated presence as a foreign guest at meetings of the British Association has passed him almost as one of ourselves. His many friends among British botanists will wish to congratulate him on carrying as a light burden his tale of years. The nature and extent of his researches brought him early into prominence. Having learned Continental methods of research in the laboratory of Kny, his own fine memoir on the Ostrich fern (1887) opened that long series of researches, the results of which he compressed into the well-known volume on "Mosses and Ferns" (1895). This book ran into its third edition in 1918. In point of detailed observation of archegoniate plants, and particularly of their development, Campbell thus proved himself a most prolific observer.

BUT the scientific stature of an investigator is not so truly measured by the volume of his output as by the acceptance of his conclusions, and their passage into the web of his subject. In January 1890, in a short memoir on "The Affinities of the Filicineæ", Campbell introduced a new aspect into the problem with which it dealt. In opposition to the views then current, he held that the relatively massive eusporangiate ferns were primitive types, while the more delicate Leptosporangiatæ were derivative. By thus inverting the current evolutionary sequence, he provided a more probable key than this to the origin of a vascular flora of the land. Others at once saw the cogency of Campbell's reasoning, while palæontology rapidly supplied its own essential substage of fact. His view was confirmed later by his own treatise on the Eusporangiatæ (1911). When consider the early date of Campbell's first statemer his generalization takes a high place in the history comparative morphology.

PROF. CAMPBELL has been a great traveller in que of material for research. Latterly he has assembl his impressions and conclusions into "An Outline Plant Geography" (1926). With modesty he offe his volume, though he confesses in the preface th he can scarcely claim rank as a plant geographe We may gratefully receive these collected impressio of a first-class observer. As a water-colour artist has also been able to record pictorially much that has seen. His sketches form a counterpoise to t vast number of his detailed drawings of plan structure and development, so many of which ha been borrowed for use in current texts.

Rights and Duties of Science

IN an article "Rights and Duties of Science" in t *Manchester School* of October 1939, Prof. M. Polan examines the Marxist claims, and particularly tho of Prof. J. D. Bernal in "The Social Function Science", for a radical reconsideration and readjus ment of the duties of science, and of the assuranc accompanying these claims that they will not impa the vital rights of science. The main points at issu are comprised in the relation of pure and applie science. A distinction between these is not admitte in Marxism, which attributes such a distinction i capitalist countries to the inner conflict of a type society which deprives men of science of the cor sciousness of their social functions. Stating th liberal view of the distinction between pure an applied science, and concerning the relation of scienc and society, Prof. Polanyi points out that, to th liberal, science represents in the first place a bod of valid ideas. Science consists of autonomou branches, ruled by their several systems of ideas, an these systems have proved permanent while wave of civilization have come and gone. In a shiftin world the mind clings persistently to the rare struc tures of sound and consistent ideas, and in thes structures all scientific interest resides.

THE direct appeal of a subject does not in itse signify scientific interest. Prof. Polanyi emphasize the mutual reactions between science and practic knowledge, and urges that attempts to direct researc towards results of possible practical applicabilit cannot lead to a growth of science that is of muc value. A consistent policy on these lines woul stop the development of science altogether, turr ing in effect the efforts now directed to scientifi research into attempts to discover empirical solution for practical problems. Prof. Polanyi condemns, fc example, cancer research, and urges that all progres depends on the freedom of the systematic branche of science to pursue their own specific scientific aim Universal adoption of a policy of endowing researc for practical aims would bring science to a standsti and gradually exhaust its practical applications.

SOCIETY, in the liberal view, cultivates science as organism of ideas which powerfully attracts the nds of intelligent people, and also to increase the re of knowledge available for practical application. is position of science in society is a significant ample of the principles of liberty, being indeed rely a special feature of the position of thought in iety. Freedom is not only possible but also a social essity when we admit that the realm of thought sesses its own life. Prof. Polanyi dissents from of. Bernal's desire to put science into the consciously ganized service of human welfare, arguing that the r attitude leads to the approval of oppression of ellectual liberty, if it is perpetrated only in pursuit approved political aims. Prof. Polanyi is on firm und in criticizing a somewhat propagandist atti-le in regard to Soviet Russia, but his sincere plea the re-establishment of man's right to pursue th regardless of social interests would have more lity if he would recognize the present lopsidedness scientific development. The reorientation of entific effort for which so many scientific workers calling involves no threat to fundamental research, ich, indeed, it is desired to instigate in fields at sent neglected.

ather Reports in the United States

CCORDING to a report which has been issued by ence Service, the United States Weather Bureau making the experiment of having both aviation ecasts and general forecasts not specially suited the requirements of aviation made by a gle staff, in the case of the new district ce of the Weather Bureau at Kansas City ort. Up to now, aviation forecasts have been de by special staffs at airports, while the other casts were made independently at Weather reau offices located in the different towns. If this eriment, which began on October 1, proves cessful, it is intended to extend it to other stations the Weather Bureau. The Kansas City district ce programme includes also a new feature that recently been introduced at Washington and timore and which has proved very popular, mely, a 'breakfast time' broadcast forecast. It is ected that this will be extended to many other erican cities in the near future. It is not stated at time is taken as 'breakfast time' for the purpose hese broadcasts, but presumably it is too late to ke the forecasts meet the requirements of farmers, must arrange what work shall be done during day at an early hour and could only take account orrespondingly early forecasts. There was before War a demand by British farmers for such 'pre-akfast' forecasts; but an obstacle in the way their realization is that an hour or two must se between the taking of the observations on ch the forecasts must be based and the time at ch they are made, to allow the information be collected, decoded, charted and critically mined, and a very large number of observers ld have to begin their day's work at about m.

Penetration of the Skin by Heat

IN a paper entitled "The Penetration of Rays through the Skin, and Radiant Energy for the Treatment of Wounds", read before the Royal Society of Arts on November 22, Sir Leonard Hill gave a useful review of our knowledge of the extent to which luminous, thermal and other radiations can penetrate the skin. He also referred to some of his own recent work on the differences in the penetrating power of heat radiation according to the nature of its source. Experiments on the production of artificial fever by means of short-wave oscillators show that the body temperature can be raised to 105°–106° F. in an hour or so.

WITH what some of his listeners may have thought a curious irrelevance to the subject, Sir Leonard delivered himself of a judgment about radium treatment, to wit "The world would, I think, be little the worse off if all the radium in the country now buried for security from bombing in deep holes, remained therein. Very big monetary influences will cry out against this". The question may well be asked whether Sir Leonard really believes that these monetary influences determine the practice of radium therapy in Great Britain. About 15,000 patients received such treatment in 1938. Are the results of so little value to cancer and other patients that Sir Leonard's advice should be taken on this subject? The Cancer Act is the country's reply to such a question.

Quantitative Estimates of Sensory Events

THE final report of the committee appointed to consider and report upon the possibility of quantitative estimates of sensory events has appeared (Sections A and J, British Association, Dundee, 1939). This committee was appointed in 1932 after Sections A and J of the British Association had held a joint session dealing with the problem. It has been reappointed each year since. In 1938 a long interim report was presented containing: (*a*) a historical statement; a summary of recent experimental work; (*b*) a statement arguing that sensation intensities are not measurable; (*c*) various notes on this statement; (*d*) a statement arguing that sensation intensities are measurable. A subcommittee was appointed to consider whether the views put forward were really irreconcilable. This subcommittee presented a draft report to the British Association this year. It now seems that agreement is impossible. This is scarcely surprising when there is disagreement as to the meaning of 'measurement'. If it is postulated that this term must be limited to its applicability in physics, then this would rule out the use of the word in relation to much psychological work. Two extreme views hold the field, and a close examination of these views by a member who holds an intermediate view leads to the conclusion that they cannot be reconciled. The report therefore consists of the views of individual members. The discussion is of value, even apart from the data here presented, as illustrating some of the difficulties inherent in such problems.

Royal Gardens of Queen Anne

A NUMBER of interesting manuscripts belonging to Lieut.-Colonel H. E. Disbrowe-Wise have lately been abstracted by Mr. F. J. Chittenden (*J. Roy. Hort. Soc.*, **64**, Pt. 10; October 1939). They relate to the part played by Henry Wise in the upkeep and rearrangement of the Royal Gardens in the reign of Queen Anne. Wise and his partner, George London, were the proprietors of the great Brompton Nursery, and directed the establishment of most of the large gardens of England at the beginning of the eighteenth century. They were responsible for the introduction of French influence in garden design, but they evidently eliminated some of the frivolities of Versailles horticulture, and used only the stateliest elements in the spacious parks, terraces and avenues of Hampton Court and other Royal demesnes. Details and costs of the upkeep are revealed by the manuscripts. Henry Wise received £1,600 a year from 1702, for the upkeep of Hampton Court, the gardens at Windsor and the plantations at Kensington. A catalogue of the varieties of wall fruit reveals some affinity with modern names, and an important side of garden activity is shown by a description of five new pears which bore fruit in the year 1715. Each of the new varieties appears to have been "very rich and melting", and doubtless played its part in the general improvement the results of which we enjoy to-day.

National Central Library

WINTER is the reading man's season. Then, as the Student says in Goethe's "Faust":

> "the pleasures of the mind
> Bear us from book to book, from page to page.
> With them the winter nights grow kind and bright,
> And every limb is warmed with happy life."

But if we want unusual books, such as, say, Bolingbroke's idea of a "Patriot King", can we get them? The answer is given by the great National Central Library in Malet Place, London. It lends books through the local libraries and regional bureaux and has access to 21 million volumes in other institutions. It can do work of national importance in helping research in science and medicine. Some irreplaceable matter has been removed to Hemel Hempstead, but the non-bibliographical books remain at the London headquarters. The latest report of the Library shows that it lent during 1938–39 more than 21,000 books to urban libraries, and more than 12,000 to country ones. The 'outlier' libraries, from which readers can borrow through the National Central Agency, now include, we notice, the British Postgraduate Medical School and the Library of Radiological Periodicals (Dr. Bernard Leggett).

Health in British India during 1937

THE state of the public health in British India and some of the Indian States during 1937 is dealt with in the recently issued "Annual Report of the Public Health Commissioner with the Government of India for 1937" (Government of India Press, New De 1939. Price Rs. 3 or 5s.). The mid-year estima population for British India was 272,406,436, an crease of more than three and a quarter millions co pared with the previous year. The birth-rate 34·5, and the death-rate 22·4 per mille, each a sli decrease over the previous year, and the infan death-rate per 1,000 live births was 161·7. Pla mortality, with 28,169 deaths, was appreciably hig than in 1936, but deaths due to cholera and smallp 99,054 and 54,810 respectively, showed large creases, so that there was a total reduction of m than 90,000 deaths from these epidemic diseases. W regard to plague, it is remarked that within rec years the fatality-rate has considerably decrea and that the disease is often so mild that patie remain at work during the attack. Malaria respiratory diseases cause the largest mortali roughly about 1,000 people die from malaria ev day throughout the year. Dysentery and diarrh caused 267,479 deaths, or more than two and a times the number of cholera deaths. With regard vaccination and its protective power against sm pox, figures show that the greater the number vaccination 'marks' the smaller is the case mortal rate, and that mortality is much the highest am those having 'no marks', which may be presumed mean absence of vaccination. The volume also c tains much information on maternity and ch welfare and on the research work of various colle and institutes.

Animal Welfare

SINCE 1931 the Universities Federation for Ani Welfare (formerly the University of London Ani Welfare Society) has published annually the Ani Year Book, a journal which has contained m useful hints on the care of animals and given evide of strenuous propaganda on behalf of the well-be of wild and domesticated animals. The Year B has now been replaced by *U F A W Quart Journal*, which continues the policy of its predece but affords means of closer contact between members of the Federation and others interested its benevolent activities. Articles of general inte in the first number discuss the ideal pet-shop an population study of rabbits. A strong and justifia plea is made for the better regulation of the impo tion and trade in Mediterranean tortoises, of wh some 150,000 are said to be imported into Gr Britain annually, often under the most objectiona conditions. It may be added, for the information readers in whose family circle a tortoise makes appearance, that pamphlets on the care of these have been issued by both the English and Scot Societies for the Prevention of Cruelty to Anima

Cave Animals

WITH the appearance of "Pars 14" (published 1938 but only recently received by NATURE) great "Animalium Cavernarum Catalogus", compi by Dr. Benno Wolf and published by Dr. W. Ju reaches completion. Anyone who has followed velopment of this work must have been astounded the number of inhabited caves which it revealed, the extent and variety of cave faunas (the index the animals itself occupies 96 pages), and at the st number of papers which have been written about em. The completed work is in three volumes, the st including introduction and bibliography (pp. 8); the second containing a list of the caves, with erature references to each and the names of the imals recorded from each (pp. 616); and the last ntaining a systematic list of the animals, with ferences to the caves in which they have been found d to the recorders (pp. 918). The three volumes e thoroughly indexed, one index of 46 pages ferring to the caves, the other (96 pp.) to the imals. The bibliography is itself alphabetically ranged so that it serves as a guide to authors. The pplement carries the information about cave unas up to the end of 1935.

ork of the Central Midwives Board

The Central Midwives Board, which controls and gulates the work of practising midwives, has issued annual report for the year ended March 31, 1939 M. Stationery Office. 4*d*. net). The number of men practising as midwives in England and ales in 1938 was 16,761, some 700 less than in the evious year. During the year covered by the report, w training and examination rules of the Board me into operation. The training rules require actising midwives to attend courses of instruction m time to time. A report on the examinations ld during the year is included, together with notes various decisions by the Board on midwives' ining, etiquette and practice. The report also fers to preparatory arrangements made by the ard for an efficient midwifery service during a tional emergency.

ospital Schools in the United States

Special educational facilities should obviously be ovided for children who must spend weeks, months even years in a hospital or sanatorium. Some tempt to meet this need has been made in the ited States, and information concerning this rvice has been collected (U.S. Department of the terior. *Bulletin*, No. 17; 1938). It is estimated at fifty or sixty thousand children in American spitals need educational facilities, but less than ght thousand appear to be receiving tuition. It is inted out that the hospital school has three values: erapeutic, vocational and general educational. It ds physical recovery by keeping the child's mind cupied and away from his misfortune.

bliography of Seismology

We have just received vol. 13, No. 1, items 4260–78 of the Bibliography of Seismology, published by e Dominion Observatory at Ottawa. In this number ere are fifteen collaborators from Europe, North merica and New Zealand, notable absences being uth America and U.S.S.R., where it is known that ismological work is being done. In addition to the particular studies of individual earthquakes, mathematical seismology and general earth structure, a considerable number of the listed papers deal with microseisms and geophysical prospecting. The latter becomes increasingly important as details are worked out and apparatus becomes more applicable to the particular problems involved, needing to be robust, sensitive, and yet transportable. It is noteworthy that item 4342 is of six patents concerned with seismic prospecting, four being U.S. patents, one Canadian and one U.S.S.R.

Seismology in the Antarctic

We learn from Capt. N. H. Heck that it is proposed to instal a seismograph, if possible on a rock foundation, at a base of the forthcoming United States Expedition to the Antarctic. This, along with the stations in South Africa, South America, Australia and New Zealand will be extremely useful in determining epicentres in the southern hemisphere where seismographic stations are all too few, and on the continent of Antarctica in particular, the seismic history of which is little known. Miss Bellamy's catalogue of 1913–1930 shows seven epicentres actually located on the continent, and the Milne seismograph of the British Antarctic Expedition from March 1902 until November 1903 (lat. 77° 51′ S., long. 166° 45′ E.) recorded 135 earthquakes, of which approximately 75 were local though none was strong enough to be felt by the explorers.

Earthquake in the New Hebrides

On instrumental reports from the seismographic stations of Georgetown, Tucson, St. Louis, Honolulu, Pittsburg, Manila, Weston, Fordham, Pasadena, Hong Kong, Phu Lien, Apia, Huancayo and Lincoln, the United States Coast and Geodetic Survey in cooperation with Science Service and the Jesuit Seismological Association has determined the epicentre of the earthquake of October 17, 1939, as having been provisionally in islands of the New Hebrides group in the Pacific Ocean. More precisely, the epicentre was situated in the sea between the islands of Malekula, Ambrim and Pentecost. This is a seismic area particularly liable to deep focus earthquakes, and this shock was no exception, being situated at a depth probably near 100 km.

Royal Academy of the Lincei

The Secretary of the Royal Academy of Italy announces that the Royal Academy of the Lincei has been amalgamated with the Royal Academy of Italy, which has taken over all the activities of the Lincei. As from July 1, 1939, the publications of the Academy of the Lincei will form part of the combined *Atti della Reale Academia d'Italia*, which will be divided into *Rendiconti* and *Memorie* of the class of moral and historical sciences and of the class of physical, mathematical and natural sciences. The publication of the *Notizie degli Scavi* will be continued without interruption by the Italian Academy. The Royal Academy of Italy will be pleased to send its publications to those institutions which received the publications of the Royal Academy of the Lincei under a system of exchange.

Chemical Club

The Chemical Club, 2 Whitehall Court, London, S.W.1, has arranged a series of 'talks' similar to those held at the Club last winter. They will, however, be briefer, and will be held after luncheon in view of the War. The first talk of the season will be given by Mr. James Kewley, chief chemist of the Royal Dutch Shell Group, on Monday, December 11, at 2 o'clock at the Club. The title will be "The Intrusions of Petroleum", and it is expected to deal with the increased range of products being manufactured by the petroleum industry which 'intrude' upon the organic chemical market. At the annual general meeting of the Club on November 14, a resolution was adopted that the facilities of the Club should be thrown open during hostilities, at a nominal subscription, to those temporarily engaged in London on Government work.

Chadwick Public Lectures

In September last it was decided, in consequence of the War, to postpone the Chadwick Public Lectures which were to have been delivered this autumn. The Trustees have now resolved to resume the lectures, and the first lecture is to be delivered on Tuesday, December 12, at 2.30 p.m., at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, W.1, when Sir William Savage is to speak on "The Health Aspects of Canned Foods". The lectures for the spring programme, 1940, will deal generally with public health matters and the War, and will be announced in due course.

National Institute of Sciences of India

At a meeting of the Council of the National Institute of Sciences of India, held on October 6 in the rooms of the Royal Asiatic Society of Bengal, Calcutta, the following were elected fellows of the Institute: *Ordinary Fellows:* Dr. K. Banerjee, reader in physics, University of Dacca; Prof. F. R. Bharucha, professor of botany and head of the Department, Royal Institute of Science, Bombay; Dr. R. N. Ghosh, reader in physics, University of Allahabad; Prof. H. K. Mookerjee, University professor of zoology and head of the Department, University of Calcutta; Prof. V. V. Narlikar, professor of mathematics and head of the Department, Benares Hindu University; Dr. C. G. Pandit, officiating director of the King Institute of Preventive Medicine, Guindy, Madras; Major C. L. Pasricha, professor of pathology and bacteriology, School of Tropical Medicine, Calcutta; Prof. L. Rama Rao, professor of geology, University of Mysore; Dr. M. Sharif, entomologist, Haffkine Institute, Bombay; Dr. K. Venkataraman, director of the University of Bombay Laboratories of Chemical Technology and Textile Chemistry. *Honorary Fellows:* Dr. E. V. Appleton, secretary of the Department of Scientific and Industrial Research of Great Britain; Prof. Charles W. Edmunds, p fessor of pharmacology and therapeutics, Univers of Michigan Medical School; Prof. R. A. Fish Galton professor of eugenics in University Colle London; Prof. Waldemar Lindgren, emeritus p fessor of geology, Massachusetts Institute of Tec nology, whose death on November 3 is announc on p. 970.

Royal Society Officers and Council

The following is a list of those elected as offic and council of the Royal Society at the anniversa meeting held on November 30: *President*, Sir Willi Bragg; *Treasurer*, Prof. T. R. Merton; *Secretari* Prof. A. V. Hill, Prof. A. C. G. Egerton; *Forei Secretary*, Sir Albert Seward; *Other Members Council*, Prof. F. C. Bartlett, Prof. P. G. H. Bosw Prof. F. T. Brooks, Dr. C. G. Darwin, Prof. H. Fox, Dr. H. J. Gough, Dr. A. D. Imms, Prof. C. Ingold, Prof. G. B. Jeffery, Prof. R. T. Leiper, Pr H. S. Raper, Sir Owen Richardson, Prof. E. Rideal, Dr. F. J. W. Roughton, Prof. W. W. Topley, Prof. R. Whiddington.

Announcements

Dr. J. B. Mennell, president of the Section Physical Medicine of the Royal Society of Medici has been awarded a gold key by the American Co gress of Physical Therapy for distinguished resear on physical therapy during the last year.

Dr. Alfred Froehlich, formerly professor pharmacology in the University of Vienna, has be appointed pharmacologist to the May Institute Medical Research of the Jewish Hospital, Cincinna

The name of the National Baby Week Council, body which came into existence during the War 1914–18, is now changed to "National Baby Welfa Council", this name being more commensurate wi the increased scope of work falling to the Counc lot under war conditions. The address of the Nation Baby Welfare Council is 29 Gordon Square, Londo W.C.1.

The Women's Medical Association of New Yo offers a Mary Putnam Jacobi fellowship to a woman doctor, American or foreign, to carry or complete some special problems in medical researc Application should be made by March 1, 1940, the secretary, Dr. Phebe L. Dubois, 150 East 73 Street, New York City.

In his latest quarterly report the Registrar-Gener states that the number of live births in England a Wales during the thirteen weeks ended June 30 w 222 more than in the corresponding quarter of 193 and amounted to an annual birth-rate of 16 p thousand of the population. The number of deat corresponded to an annual rate of 11·7, and t mortality of infants under one year of age to a annual rate of 48, which was 8 below the average the preceding ten second quarters.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 982. CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

alysis of Protein by Means of Deuterium-containing Amino-Acids

As is well known, the analysis of amino-acids giving colour reactions is very difficult as most of the thods known lead to inevitable losses. This ficulty can, however, be overcome in the following y.

To the hydrolysed protein, of which the leucine ntent for example is to be determined, is added a own amount of leucine labelled by introduction deuterium in the (C—H) position. After mixing, me leucine is isolated from the mixture by the ual methods.

The next step is the determination of the deuterium ntent of the leucine mixture isolated. Where the otein does not contain leucine, the leucine sample covered should be pure 'heavy' leucine; while m the protein containing normal leucine a mixture 'heavy' and normal leucine is recovered.

From the deuterium content of the leucine mixture lated we can calculate the proportion in which e 'heavy' leucine added is diluted by the leucine iginating from the protein.

The mixture of amino-acids which is the result of e usual acid hydrolysis consists (with the exception glycine) of optically active forms, whereas the ual methods for synthesis of amino-acids containing uterium leads to racemic mixtures. It is necessary erefore, either to perform a resolution of the synetic product into the *d*- and *l*-forms, or to racemize e amino-acid to be estimated in the hydrolysate. e last path, being by far the least expensive, is llowed here.

Deuterium-containing *dl*-leucine was prepared by ating *l*-leucine with 33 per cent sulphuric acid ntaining, say, 7–10 per cent D_2O in a sealed pyrex be to 170° for twenty-four hours[1].

After removal of SO_4^{--} and repeated evaporation the water and re-dissolving in pure water, all uterium in combination with oxygen and nitrogen removed, and a portion of deuterium is left which nnot be removed by boiling water. As the leucine now optically inactive, as was determined in two ses, the stable linked deuterium has obviously tered the molecule during the racemization and linked to the α-carbon. Under the treatment entioned, the destruction of leucine did not exceed o per cent. The determination of the deuterium ntent of combustion water from the leucine is rformed by the gradient-tube method of Linderrõm-Lang[2].

3·0 gm. dry hæmoglobin was hydrolysed and cemized by treatment with 33 per cent sulphuric id in a sealed ampoule at 170°. The hydrolysate s mixed with 0·392 gm. 'heavy' leucine. Sulphuric id was removed, the amino-acid mixture dried and powdered. The powder was extracted with dry propionic acid (method of Przylecki and Kasprzyk) which extracts the hexon bases, proline and part of the leucine. Propionic acid was removed and the leucine isolated as copper salt and purified by recrystallization from water. The excess density of the water formed by combustion of the 'heavy' leucine was 518 parts in a million, that of the leucine mixture isolated 225 parts in a million. The amount of 'heavy' plus normal leucine was:

$$0{\cdot}392 \times \frac{518}{225} = 1{\cdot}262 \text{ gm.}$$

The amount of leucine originally present in the protein was

$$1{\cdot}262 - 0{\cdot}392 = 0{\cdot}870 \text{ gm.},$$

which corresponds to 29 per cent of the hæmoglobin.

A second estimation gave 30 per cent. An estimation of the leucine content of gelatine gave 8·5 per cent.

These results should, of course, be regarded as examples only. It should be possible to adopt the method for a series of amino-acids, for example, alanine, valine, isoleucine and aspartic acid, for which to my knowledge no quite reliable estimation methods are known.

A Mucolytic Enzyme in Testis Extracts

WE have recently described a polypeptide, isolated from peptic protein hydrolysates, which is chemotactic to leucocytes and increases the permeability of capillaries[1]. It is probably closely related to Menkin's 'leukotaxine'[2]. As a result of this work we became interested in another permeability-increasing substance, known as the 'spreading factor'[3]. This substance, which is present in large amounts in testis extracts and certain bacterial filtrates, is a protein and is active in dilutions so low as 10^{-8}. It acts by increasing the permeability of the dermal layer of the skin, as demonstrated by the flattening of the wheal and the rapid spread of intradermally injected solutions of dyes, bacterial toxins and particulate matter in suspension.

So far, nothing has been known about the mechanism of the action of the spreading factor. From its properties, it seemed to us likely that it was an enzyme acting on some substrate in the skin, causing the removal of a barrier to the rapid diffusion of intradermally injected fluids. We have therefore examined extracts of testis, purified by the method of Morgan and McClean[4] for the presence of different hydrolytic enzymes. Our purified testis extracts contained 0·3 per cent of dry material which produced marked spreading in dilutions of 10^{-4}.

Though the testicular extracts were found to contain a proteolytic enzyme of cathepsin character, it seemed improbable that the action of spreading factor was proteolytic, since active preparations of crystalline trypsin (kindly supplied to us by Dr. H. Holter and Prof. Linderstrøm-Lang) did not give any reaction characteristic of spreading factor.

Histological evidence of the existence in the skin of a mucin-like inter-fibrillar substance[5] led us to examine the possibility of the enzymatic action of spreading factor solutions on mucins of different origin. We found that the extracts had a remarkable action on synovial fluid, the viscosity of the latter, measured in an Ostwald viscometer, falling to 1/300 of its original value (being then approximately that of water) when 5 c.c. of the fluid was incubated at 37° for 30 minutes with 0·5 c.c. of testicular extract. This effect was found to be due to the action of an enzyme on a polysaccharide in the synovial fluid, with the liberation of reducing substance (see accompanying table). No liberation of reducing substance was found in a control experiment in which synovial fluid was incubated for 18 hours at 37° with heat inactivated spreading factor solution.

AMOUNTS OF REDUCING SUBSTANCE IN γ, EXPRESSED IN GLUCOSE EQUIVALENTS (METHOD OF MILLER AND VAN SLYKE[6]), IN SAMPLES OF 1 C.C., TAKEN AT DIFFERENT TIME INTERVALS FROM 20 C.C. SYNOVIAL FLUID INCUBATED AT 37° WITH 2 C.C. OF TESTICULAR EXTRACT

0 hours	34
½ ,, ...	32
1 ,, ...	65
2 ,, ...	105
4 ,, ...	158
6 ,, ...	192
18 ,, ...	274

With Elson and Morgan's[7] test the reducing substance gave the colour reaction for *N*-acetylglucosamin. Quantitative determinations on 10 c.c. synovial fluid incubated for 18 hours at 37° with 1 c.c. of testicular extract demonstrated the appearance of 245 γ/c.c. of *N*-acetylglucosamin. The control experiment set up under identical conditions with heat inactivated testicular extract gave entirely negative results. The split products obtained by dialysis gave a Bial reaction for glucuronic acid. Furthermore, while synovial mucin is precipitated by dilute acetic acid, forming characteristic strings, synovial fluid after incubation for 30 minutes at 37° with 1/10 of its volume of testicular extract yields very much less precipitate with acetic acid, while after 60 minutes the solution remains clear. Since the enzyme brings about the disappearance of the most characteristic property of synovial mucin, it can be called a mucinase.

Testicular mucinase was found to act also on a polysaccharide present in vitreous humor, the liberation of reducing substance (expressed in glucose equivalents) from 15 c.c. of dialysed vitreous humor incubated for 18 hours with 1·5 c.c. of testicular extract being 71·5 γ/c.c.

Further work is in progress on the properties of the enzyme and its substrates, especially on the relationship of the latter to the polysaccharides from umbilical cord, vitreous humor and synovial flu isolated by Meyer and Palmer[8] and Meyer, Sm and Dawson[8].

Since the properties of the mucinase are identi with those of spreading factor, and since the occurre of spreading factor in bacterial filtrates has so been found to go parallel with their mucinase conte we think it probable that mucinase and spread factor are identical. We are undertaking furt experiments in the hope of being able to prove t point conclusively.

Vitamin A Content of the Livers of a Hundred Healt Dogs

ALTHOUGH under natural conditions largely car vorous in its dietary requirements, the domesticat dog will accept with apparent relish a diet m fitted for an omnivorous or even vegetarian anim Flesh, milk, cereals and vegetables make up the bu of the ration, the proportions of these varying acco ing to the fancy or perhaps the financial circumstan of the owner. Thus the amount of vitamin A ava able to the dog will vary greatly.

Holmes *et al.*[1] found that under the conditic obtaining on a fur farm from which they obtain their material, the vitamin A content of the liver the mink and the racoon was less than that of w specimens of these species. However, they a showed that two wild opossums, captured and fed captivity for six months on a diet of high vitamin value, were able to store the vitamin to a mu higher extent than three wild opossums which h been captured at the same time as the above tv and were destroyed.

Bradfield and Smith[2] found considerable variatio in the vitamin A content of the liver in dogs whi were being fed, under controlled conditions, on equ amounts of vitamin A. Chevalier and Choron[3] show that in 100 guinea pigs fed on the same diet, var tions occurred in the vitamin A content of the li of from 5–10 blue units per gram to 300 blue un per gram. Simmonet *et al.*[4] found considerable var tions in the vitamin A reserve of the liver of clinically normal dogs.

That the liver of newborn puppies contains lit vitamin A reserve was shown by Busson and Si monet[5], who found their liver to be inactive ev when that of the dam contained an ample store.

The dogs used for the present work were unwant dogs, which had been destroyed by coal gas poisoni They were not bled. The histories of these anim were not obtained. They were probably all city do and were presumed to be healthy.

Technique. A piece of liver was removed within a w hours after death, placed in cold storage over- ght, and on the following day 5 gm. was weighed it in duplicate, minced with scissors, 15 c.c. of per cent caustic potash added, and kept in cold ore if not being dealt with immediately.

The vitamin was extracted according to the method Davies[6]. The unsaponifiable portion was dissolved 10 c.c. of chloroform, and the blue units determined the use of a Lovibond tintometer. In the large ajority of cases, an amount of the chloroform lution was taken such as would give a reading of ue units between 3 and 6, but readings slightly yond this range were used as the basis for cal- lating the results in a minority of cases.

Results. Great variation in the liver reserve of gs has been found to occur. Whether this is sociated with the amount of vitamin available in e food, or with the ability to absorb and store it the liver, is not here indicated. The average of ese reserves was found to be 678 B.U./gm., but, as inted out by Moore[7], the average figure may be isleading owing to the wide variations, and the edial figure is a more reliable one to take as an dication of a standard. The medial figure in our ries (taking an average of the six central figures) 153·5 B.U./gm.

The exact age of these dogs was not known. Six nich were only a few months old gave values 9, 10, , 47, 62 and 70 respectively. At the other extreme life, greater variation in the vitamin store appeared occur. In seven old dogs the values were 26, 36, 3, 171, 206, 340, 1125.

In twenty-three lean or poor-conditioned dogs, the erage vitamin A content was 415·8 B.U./gm., with range of from 11 to 2800, and in three very fat gs the figures were 8, 171, 447. From these limited ta there does not appear to be an association tween the vitamin A reserve and the body condition the dog.

Moore[7] showed that in the rat a condition of treme emaciation did not necessarily lead to a minution of the vitamin A reserves of the liver, d one of us (R. G. L.) found large reserves in the ers of hens and geese that had been starved to ath by their owner.

R. G. LINTON.

Monogenic Broods in *Armadillidium vulgare* Latr.

VANDEL[1] has found that in the woodlouse, *Tri- oniscus provisorius*, there occur both amphogenic oods (broods containing approximately equal mbers of both sexes) and monogenic broods oods consisting of one sex only or very nearly so). e accounts for the occurrence of arrhenogenic oods (broods consisting of males only) and thely- nic broods (broods containing only females) by suggesting that in woodlice the female is the heterozygous sex (chromosomes XY) and that the segregation of the sex chromosomes in monogenic females is controlled by the cytoplasm. Thus in arrhenogenic females every egg receives an X chromosome and the Y chromosome always passes into the first polar body. Such a female, therefore, produces broods containing only males.

One of the main arguments for accounting for monogenic broods in this way is that the male has no effect on the type of brood produced. Vandel's evidence for the male having no effect on the type of brood produced is that in several cases all the females of any one brood mated with either 'ordinary' males (from amphogenic broods) or with 'exclusive' males (from arrhenogenic broods) produced either all arrhenogenic or all thelygenic broods. Sister females thus resembled each other in producing the same type of monogenic brood no matter what type of male they were mated with.

Amphogenic and monogenic broods have also been found in the woodlouse *Armadillidium vulgare* Latr. by Howard[2] and Vandel[3]. By mating males of *Armadillidium* to two or more females I have also been able to show that the male has probably no effect on the type of brood produced. The same male mated to two different females may produce both arrhenogenic and thelygenic broods or both amphogenic and monogenic broods. The data are given in the table.

Parents of brood		Constitution of brood	
Male	Female	Males	Females
B	*A*	1	36
B	*AB*	22	9
AM	*AB*	34	8
AM	*AJ*	6	50
AL	*CB*	1	37
AL	*CC*	0	25
AL	*CD*	64	0
AN	*BK*	45	0
AN	*U*	0	56
SB	*DA*	0	30
SB	*EA*	46	47

It seems, therefore, very probable that it is the female which determines the type of brood produced. It has also been possible by using different genetical types to show that neither arrhenogenic nor thelygenic broods are due to parthenogenesis.

The above data also have another interest. The three females, *CB*, *CC*, and *CD*, are all from the same brood. One brood may, therefore, contain both arrhenogenic and thelygenic daughters. Also female *BK*, parent of an arrhenogenic brood, was a daughter of a thelygenic female (female *A* in the table). Such facts will have to be considered in suggesting schemes for the inheritance of arrhenogeny and thelygeny. It seems possible that while the male has no effect on the sex ratio in a brood, he does have an effect in determining the types of females produced.

Hypertensin: the Substance Causing Renal Hypertension

AN increase in blood pressure is produced by compression of the renal artery[1] or by injection of the venous blood of the kidneys[2]. The filtrate obtained after adding 3 vol. of acetone to the serum of this blood contains a pressor substance which is insoluble in ether and amyl alcohol, soluble in glacial acetic acid and is destroyed only after three hours boiling in normal hydrochloric acid. The same substance is formed on incubating for fifteen minutes at 37° the kidney protein renin[3] with blood serum or its pseudo-globulin fraction. This substance, which we name hypertensin, is different from adrenalin, tyramin, pitressin and urohypertensin. Renin appears to be a proteolitic enzyme of the papain type, which liberates hypertensin from a blood protein belonging to the pseudo-globulin fraction.

Relation of the Nucleolus to Secondary Constrictions

IN discussing the relation of the nucleolus with the *SAT* chromosomes, investigators do not appear to notice that the 'constriction' is probably *due* to the nucleolus, rather than an active producer of that body[1]. I imagine the chromosome in a close spiral. The nucleolus develops at a definite point in the chromosome and pushes the spirals apart until that part of the chromosome becomes a straight thread and apparently much thinner than the remainder of the chromosome. When the *SAT* chromosome in Navashin's Crepis[2] was not able to develop a nucleolus because the nucleolar material had already been removed by another chromosome, it had no satellite either. The darkly staining portions just below the thin stalk in McClintock's Zea chromosomes[3] could also be explained by the spirals beyond the nucleolus being pushed more closely together.

That a nucleolus can interfere mechanically with a chromosome is seen clearly in the salivary glands of Chironomus, the chromosomes in which often have enormous nucleoli. Here the usually fused homologues are seen to be separated in the region of the fused nucleoli and the chromatin of each homologue also is often much dispersed[4,5].

[5] Melland, A. M., unpublished.

IT is true, as Miss Melland states, that the nucleo
as it grows can interfere mechanically with t
structure of a chromosome. It can, for examp
stretch the filament which connects the satellite w
the body of the chromosome. This is done by
spiralizing the filament. Nevertheless the filame
appears to be a spiral of a lower order than the spi
chromonemata which make up the body of t
chromosome. It is already present in anaphe
chromosomes before the nucleolus begins to appe
The same is true of secondary constrictions whi
give rise to nucleoli. These features of chromoso
structure are for this and other reasons not produc
by the growing nucleolus merely pushing the gy
of the spiral chromonema apart.

It is not possible to discuss the subject more
detail here. A series of papers are now in the pr
dealing with nucleolar production in a number
plant genera. The conditions vary in some respe
from genus to genus, but there is evidence of vari
kinds that the nucleolar secondary constrictions
well as the nucleolar body in a *SAT* chromosome
definite loci of the chromosome, and that the secon
ary constrictions are already determined before t
nucleolus begins to appear in telophase.

Calcium in Ciliary and Muscular Movement

IT is interesting to note that the *unbalance* obtain
by reducing the calcium content of physiologi
solutions can to some extent be offset by the additi
of small quantities of lipoids to the solution. Th
frog heart rendered hypodynamic, or even arreste
by Ringer solution less varying amounts of calciu
chloride, can be made to beat normally again
adding small quantities of sodium oleate, of sodiu
palmitate, of impure lecithin, or of ox blood thromb
to the Ringer, the *p*H being maintained unaltere
The effect was not observed with very pure lecith
or very pure kephalin, but a similar effect w
obtained with lyso-lecithin, which first reduces t
beat and also contracts the heart. Similarly, Cla
and others[1] have shown that frog heart render
hypodynamic by prolonged beating in Ringer soluti
shows increased activity when given extra calciu
sodium oleate, impure but not pure lecithin, impu
but not pure kephalin, or serum. Ox blood thromb
serum, and all but the purest samples of phospholip
contain traces of soaps which may well account
the activity of these substances in offsetting calciu
deficiency. Mytilus cilia will beat for some time
artificial sea water at *p*H 6·5, but are quickly arrest
if they are put in a similar medium at the same
without calcium (removed as chloride)[2]. The cilia
beat is restored in such a calcium-free solution
the same *p*H if traces of one of the following su
stances are added: sodium dodecyl sulphate (t
magnesium present rendered the oleate and palmite
of sodium insoluble and therefore ineffective), hex
decyl-trimethyl-ammonium bromide, lyso-lecithin, i
pure lecithin, or ox blood thrombin. Triolein, sodiu
butyrate and sodium glycerophosphate showed
restorative effect. In considering these facts, it shou
be noted that calcium is found to be more acti
under lipoid than under protein monolayers.

Heilbrunn[3] maintains that at least in some typ cells stimulation causes a liquefaction of the gel- e cell cortex with release of calcium, some of which transferred to the cell interior, which ultimately ates or clots by a process similar to the clotting blood. Fat-solvent anæsthetics favour release of cium from the cortical plasmagel but prevent ernal clotting. Plasmagel is formed by a clotting- e reaction from plasmasol, and Heilbrunn calls this cess the 'surface precipitation reaction'. Mitosis l fertilization are processes fundamentally akin to itation, according to Heilbrunn, who says that y involve liquefaction of the plasmagel and a sequent clotting of the plasmasol which only omes fluid again at the first appearance of the ndle. Needles dipped in serum are more active producing parthenogenesis than those undipped[2]. rombin accelerates mitosis in tissue culture[3], and arin inhibits it[3]. Heparin at 1 : 100,000 also ibits the formation of fertilization membranes in hinus eggs[4]. The similarity of the effects of ion- ance on muscular, ciliary, and amœboid move- nt are well known[5]; calcium is released during scular activity[3] and at the tip of an advancing œboid pseudopod[6]; and most modern authors ee that gelation and solation are primarily re- nsible for amœboid movement.

t is submitted that the observations recorded ve are essentially in agreement with the hypo- sis of Heilbrunn that has just been discussed, and gest that it can be extended to ciliary movement. ther studies of ion balance in the cases of living ues and of inanimate lipo-protein systems are essary if these suggestions are to be followed up.

eilbrunn[3] also points out that many partheno- etic agents cytolyse Echinus eggs by destroying iquefying the plasmogel cortex of the egg, and also ate the cell interior when used at higher con- trations than those required for normal partheno- esis. Thus an agent that stimulates at low con- trations cytolyses at higher concentrations. A allel to this is the action of stronger solutions of ium dodecyl sulphate, of hexadecyl-trimethyl- monium bromide, or of lysolecithin on Mytilus cilia, e the arrested cilia first start to beat and continue beat in calcium-free solutions for some time after olysis has all but destroyed the form of the in- idual cilia.

he cytolysis by sodium dodecyl sulphate and by xadecyl- methyl- monium mide sug- s that the ry surface rgely lipoid ature[7]. It also been nd that pro- monolayer orbents or persants, h as sub- uted 4-4′-dihydroxy diphenyl or stilbene com- nds which affect protein films at 1 : 2,000,000[7] tannic acids, do not affect the beat of Mytilus at low concentrations. The cilia are relat- y insensitive to cytolysis by saponin or by ra venom; the former penetrates films of ain sterols[8] and the latter releases lyso-lecithin n lecithin by lecithinase action, and lyso-lecithin lf has been found to cytolyse the cilia. Similarly Paramecia are affected by both lipoid and protein film adsorbants[7].

These facts suggest that all cells which show movement have some lipoid constituents in their surfaces, that the movement normally requires calcium, and that calcium lack can be offset by external supplies of certain lipoids. If Heilbrunn's suggestions are correct, cytolysis and stimulation liquefy the cell membrane and liberate calcium, which coagulates the cell interior by a process related to the clotting of blood. A study of ion balance in lipo-protein systems and of the role of lipoids in muscular action should help elucidate the problem.

Spectrum of the Torch Discharge

THE so-called 'torch discharge'[1] (*Flammenbogen*[2]) in air, which can be created at a single electrode in the ultra high-frequency undamped oscillation circuit ($10^7 \sim 10^8$ Hz.), has been the subject of some investigations, but the main interest has been directed towards its chemical aspect; no attempts seem to have been made to study its spectrum. With the view of gaining an insight into the mechanism of the discharge, we have carried out an extensive examination of the spectrum.

In the flame part of the discharge, the spectrum consists chiefly of the O_2 (Runge), NO(γ) and OH bands, while in the neighbourhood of the electrode the N_2 and N_2^+ bands, as well as some easily excitable lines of the electrode material, come out with strong intensity. From all portions of the flame a continuous band extending from about 6000 A. up to the red end is emitted; its origin is unknown, but one may be able to infer fresh interpretation as to the mechanism of the chemical reactions going on in the discharge. With increasing current density NH (*Q* branch of the 3360 band) also makes its appearance, and the metallic lines of low excitation potentials

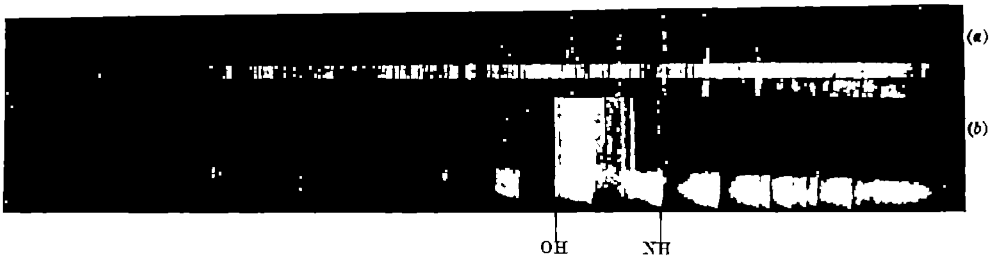

Fig. 1.

extend into the flame (Fig. 1*a*). The spectrogram of the pure oxygen band, which is obtained in the torch flame in oxygen at atmospheric pressure, is reproduced in Fig. 1*b*.

If the torch is struck in a closed vessel containing air, the absorption bands due to NO_2 appear in the visible and near ultra-violet region, and the NO (0,0), (1,0) bands become 'self-reversed'.

It is to be noted that the torch spectrum is found to be essentially the same as that of the high-tension D.C. arc[3] (*stromstarke Glimmentladung*[4]), so that, so far as the nature of the spectrum is concerned, no features distinctively characteristic of the ultra high-frequency oscillations can be detected.

A complete analysis of the Runge band will be published elsewhere.

Comparing Resistances of Four-Terminal Resistors

Two communications regarding the comparison of four-terminal resistances, the first by Mr. Arvon Glynne and a further one by Prof. John Dowling, have recently appeared[1] in NATURE.

I would like to point out that the method describ by Mr. Glynne is already well known and will found in Law's "Electrical Measurements", publish by the McGraw-Hill Book Company, first editic 1917, on p. 190, where the identical formula is giv

There is considerable practical difficulty in app ing this method, first owing to the presence of therm electric effects at the terminals, which are usua different for each position of the galvanometer, a secondly, owing to the dependence on the constan of the connexion between the two resistances unc test. In order to obtain accurate comparisons, would be necessary to compensate for the therm electric effects and to make the change-over fr position one to position two with great rapidity. T cannot easily be done when the resistance *B* has be altered for the two balances.

To overcome these difficulties, I modified t method[2], and the complete instrument was exhibit at the Physical Society in January 1938. This meth has been in continual use for precision comparis since then, with the addition of a circuit for co pensation for thermal E.M.F.'s at the terminals. T compensating circuit avoids the use of two zeros the galvanometer—one for each balance.

Points from Foregoing Letters

HANS H. USSING describes a method of analysing protein by means of amino-acids containing deuterium. The author claims that the method overcomes the difficulty met with in most types of amino-acid analysis, which usually lead to inevitable losses and are therefore only approximate. He also suggests that his method can be used for such an amino-acid series as alanine, valine, isoleucine and aspartic acid, for which no very reliable methods of estimation are at present known.

E. Chain and E. S. Duthie report on an enzyme occurring in purified 'spreading factor' extracts from testis hydrolysing rapidly a polysaccharide in synovial mucin with liberation of reducing sugars. A large and rapid decrease in viscosity occurs during the early stages of hydrolysis and the mucin becomes non-precipitable by dilute acetic acid. The possible identity of this enzyme with 'spreading factor' is discussed.

The vitamin A content of the liver of a hundred presumably healthy dogs was found by R. G. Linton and A. Brownlee to average 678 'blue units' per gram of liver tissue, with a medial figure of 153·5 and a range of 4·5 to 19,625.

In *Armadillidium vulgare* Latr. there are found broods consisting of one sex only. H. W. Howard finds that the male parent probably has no effect in determining the type of brood produced. This supports Vandel's theory that the segregation of sex chromosomes is determined by the cytoplasm of the female.

J. M. Muñoz, E. Braun-Menéndez, J. C. Fasciolo and L. F. Leloir report that renal hypertension is caused by the formation of 'hypertensin', a substai which is different from other known pressor su stances. It has been found in venous blood ischæmic kidneys and can be prepared *in vitro* by t interaction of renin and pseudo-globulins of norm serum.

A. M. Melland stresses the probability of t nucleolus *producing* the secondary constriction in chromosome, rather than the nucleolus *arising* fr that constriction. R. Ruggles Gates, commenting this letter, points out that while the growi nucleolus can separate the gyres of a chromoso spiral, yet the nucleolus takes its origin at a p determined locus of the chromosome whether t latter has a satellite or a secondary constriction.

The unbalance obtained by reducing the calci content of physiological solutions can to some exte be offset by the addition of small quantities of lipo to the solution in the case of the beating of fi heart and of Mytilus cilia. According to G. S. Car *et al.*, the use of adsorbants and dispersants of prot film and of lipoid film suggests that ciliary a muscular cell membranes have some lipoid c stituents on their outer sides. It seems that the r of lipoids in questions both of ion balance and muscular activity needs investigation. The data not inconsistent with the hypotheses of Heilbru concerning mitosis and excitability.

D. C. Gall gives an earlier reference and comme upon a method of comparing four-terminal resistanc recently described. Attention is also directed to improved method.

RESEARCH ITEMS

gan Colour-Vision

ATA of colour-vision among Polynesian Tongans re collected by Ernest and Pearl Beaglehole in the urse of a field trip to Tonga, employing the Ishihara s (seventh edition). Results are recorded in *Man* November 1939. 135 Tongans were examined ale, 67; female, 68). Five males appeared to be l-green blind; but no case of female red-green ndness was detected. No cases of blue-yellow ndness, or of complete colour-blindness, were ected in either sex. A comparison of the per- tage of red-green blindness in Tongan males (7·46) h comparable results in Whites (8·03), American groes (3·7), American Indians (1·7), taken in con- ction with the weight of evidence from all test ults available, suggests a possible racial difference he incidence in males of red-green colour-blindness. the five Tongan males with defective colour vision, were completely green-blind. The proportion of en-blindness to red-blindness among Whites, groes, and American Indians as reported is also the approximate ratio of three to one. Another uliarity in Tongan subjects is the response of tain of them in the test to plates which can scarcely read by normal subjects. These Tongans (10 male, female) were otherwise normal. In regard to eral colour discrimination a number of colour- mes were collected—cream-white, skin-white, low or gold, yellow, red, black. There is no cific colour-name for blue, nor possibly for green her. Many descriptive colour-names are in use, as example, colour-sea = blue; obscure, indistinct = wn; *kupesi*, stencil for marking bark cloth = dark wn; *loufusi*, banana leaf = deep green. Degree saturation is expressed by such qualifying words *mama*, light, *fakapo' opouli*, dark. The absence of tain terms, for example, for blue, does not imply oor colour discrimination, but is due to a difficulty finding words to describe them, and arises from a tural origin.

nee Archæology

N planning the work of the Nebraska Archæological rvey established in 1929, Dr. W. D. Strong sug- sted a line of attack which would establish a time uence from known historic to unknown prehistoric. e Pawnee for various reasons offered the most suit- le material for the first systematic attempt at lating a historic archæological complex in Nebraska. ring the nineteenth century, with two or three parent exceptions, Pawnee villages centred about confluence of the Loup with the Platte River, nding on terraces or second bottoms well out of ch of the floods. Beyond the tree-fringed water- urses are the dry, formerly grass-covered uplands table only for hunting; but it was the fertile er-bottoms, with abundance of wood, water, arable und and shelter, which determined the location their villages. The extreme limits of Pawnee tlement were on a 120-mile stretch of river valley, ng which they shifted continually, but leaving it y for seasonal hunting. The sites show a somewhat adent aboriginal culture, yielding also iron, copper, ss and glassware. Within this area but with more ited distribution are found sites with a more abundant, superior culture and smaller quantities of white contact material. Generally the sites are large (50–100 acres or more), compact and selected with an eye to defence, some having earth-walls and ditches for protection. Excavation on these proto-historic sites has produced evidence which has been assigned to a 'Lower Loup focus', while another culture, possibly contemporary, has been revealed at Leary in south-west Nebraska, to which the name Oneota culture has been given. The relations of Lower Loup, Oneota and historic Pawnee have been discussed by Waldo R. Wedel (*Smithsonian Misc. Collect.*, 97, 7; 1938) in the light of analysis of material culture and examination of the documentary evidence of early travellers. By some it is maintained that Lower Loup is more closely related to Oneota than to historic Pawnee, but analysis of cultural traits points to the closer relation of Lower Loup and historic Pawnee, the probability that the former is ancestral to the latter, after a period of decadence, being rendered stronger by the absence of any evidence that settlements, of the size and importance indicated by the sites, were made here by a sedentary, horticultural people other than the Pawnee since the arrival of Europeans.

The House-Sparrow in Canada

THE house-sparrow (*Passer domesticus*) has been long established in Canada, and a recent investigation by Richard Lee Weaver suggests that it reached its peak of abundance several decades ago, and since then has in some parts declined in numbers (*Canadian Field-Nat.*, 53, 95; October 1939). In general, the northern limit appears to be determined by the limit of systematic cultivation, although occasional colonies persist beyond that boundary in the neighbourhood of settlements. Occasionally, too, specially favourable conditions induce a northward movement, such as established the birds at Churchill, on Hudson Bay, but in such cases the severe winters cause many deaths, and at Churchill the danger of extermination is circumvented only because the sparrows inhabit in winter the railroad roundhouse, where they get shelter and food from man. The change in locomotion from the horse-traffic of early days to the motor-car has made extraordinary differences in the sparrow population in towns, for the hordes of sparrows which once, according to a note by the Ornithological Editor, made sidewalks unusable and in another way interfered with church services, have disappeared with the disappearance of horses and the droppings which formed a main food supply in winter.

Reproduction of the Spotted Hyæna

SOME unestablished peculiarity about the sexual anatomy and physiology of the spotted hyæna (*Crocuta crocuta*) led writers of antiquity to assert that it was hermaphrodite. Scientific study of the subject has been meagre, but this statement no longer holds good in view of the investigation of L. Harrison Matthews, who travelled to East Africa to study the animal and records the results of the examination of 103 individuals (*Phil. Trans. Roy. Soc. Lond.*, Ser. B, No. 565, 230, July 1939). This random sample had a sex ratio of 61·1 per cent of males. The anatomical puzzle arose from the peculiarity of the female genitalia, which possess a clitoris, perforated by the urinogenital canal, so similar to the penis of the male that male and non-parous females are indistinguishable externally. There is no annual breeding season for the female in Tanganyika Territory, all stages of sexual activity being found at the same time. In the absence of fertilization, a dicestrous cycle of about a fortnight occurs. Following fertilization, gestation lasts about 110 days, the lactation period extends over six months, and the complete sexual cycle lasts nearly a year. The author suggests that the peculiar male facies of the female may be produced by an excess of androgenic substances, accompanied probably by a deficiency of œstrogenic ones, derived from the ovary. The limit of life of the spotted hyæna appears to be about ten years.

Choice of Water by the Honey Bee

C. G. BUTLER of the Rothamsted Experimental Station has described the habit of bees collecting water from many undesirable sources that are often choked with decaying organic matter (*Bee World*, November 1939). It seemed, therefore, of interest and importance to discover what attracts bees to such sources of water. In his experiments most of the salts essential to animal life were tested in various concentrations against distilled water. Only in the case of very dilute sodium chloride and ammonium chloride were the bees attracted more than to distilled water. The optimum concentration was between 0·15 per cent and 0·07 per cent; with progressively stronger solutions the bees showed increasing preference for distilled water. Rain water, from a leaf-choked gutter, was next taken and tested against distilled water and the salt solutions. More than 90 per cent of the bees chose the rain water. Further experiments showed that bees were being attracted to this source of water by smell alone, and that their liking for very dilute salt solutions has little or nothing to do with their finding a source of drinking water. It is suggested that it is best to fill apiary drinking fountains with rain water to which is added sufficient sodium chloride to make it into a 0·1 per cent solution.

Water Movement and Radial Growth in Trees

W. R. C. HANDLEY has recently published some observations on the effect of prolonged chilling on these processes (*Ann. Bot.*, N.S., 3, No. 12, 803; 1939). By subjecting woody shoots of young saplings of ash and sycamore to continuous cooling to 2° C. during the season of growth, radial growth was almost completely inhibited, though not extension growth (which was, however, later in starting and proceeded more slowly). When cooling was extended to 0° C., leaf-wilt occurred owing to still further reduction in water conduction. Turgidity recovered on raising the temperature again to 2° C.

Wound Hormones in Plants

J. English, J. Bonner and A. J. Haagen-Smit (*Proc. Nat. Acad. Sci.*, 25, 323–329; 1939) have isolated a crystalline substance of composition $C_{12}H_{20}O_4$ which is capable of inducing renewed cell division and cell extension in parenchymatous cells. This substance was isolated from fresh bean pods. The activity of the substance is about a hundred times that of the original material, but this varies considerably. This variation is probably due to the fluctuation in the amount of co-factors in the t material. Such co-factors have been identified dur the chemical preparation, while sucrose and glutar acid were found to increase greatly the activity the di-basic acid $C_{12}H_{20}O_4$.

Aphid Vectors of Sugar-cane Mosaic

THE aphid *Aphis maidis* has been recognized fo considerable time as a transmitting agent the sugar-cane mosaic virus. H. D. Tate a S. R. Vandenberg have shown, however (*J. Ag Res.*, 59, No. 1, 73–80, July 1939), that two ot aphids, *Carolinaia cyperi* and *Hysteroneura setar* which may occur on the crop in Porto Rico, are a vectors of this particular disease. These inse inhabit the weeds *Cyperus rotundifolia* and *Eleus indica* (goosegrass), which are common in sugar-ca plantations, and doubtless play a considerable p in the spread of mosaic under field conditions. fourth kind of aphid, *Sipha flava*, was unable transmit the virus. The results supply yet anot instance of the close relation between a virus and insect vector.

Indirect Damage by Narcissus Leaf Diseases

RESULTS of several recent investigations into damage caused by fungi the general attack of whi upon their host plants appears to be slight ha often revealed more extensive indirect damage. Su a state of affairs has now been demonstrated P. H. Gregory for several leaf diseases of the narcis ("R.H.S. Daffodil Year Book", pp. 49–53, 193 Leaf scorch, caused by the fungus *Stagonosp Curtisii*, white mould, which results from the paras *Ramularia vallisumbrosæ*, grey mould (*Botrytis n cissicola*) and fire (*Sclerotinia polyblastis*) are wi spread in the commercial bulb districts of the sou west of England; but it is not certain whether th invariably cause substantial loss of the crop. Gregory has shown that their indirect effects, at a rate, are quite substantial. The leaf spotting fu spread upon the foliage after the time of floweri and often curtail photosynthesis, so that subsequ flower crops are affected. Spraying the foliage w Bordeaux mixture resulted in increased bulb weig enhanced flower quality, and, most important of considerably greater flower crop. Gains in flo production as high as 70 per cent over unspra foliage have, in fact, been recorded. Further measu of plant hygiene, such as the removal of infec foliage and flowers, are recommended, whilst rout lifting and replanting of the bulbs usually era cates the diseases if fresh foliar infection does occur.

Structure of Complex Fluorides

AMONG compounds of the type R_2MX_6 (R = NH_4; M = Si, Ge, Sn, Ti, Zr, Mn) only the fl silicates have been prepared in crystalline modifi tions possessing the fluorite-like arrangement of and MF_6^{--} ions known as the ammonium chlo platinate type. J. L. Hoard and W. B. Vinc (*J. Amer. Chem. Soc.*, 61, 2849; 1939) have examin by the X-rays the atomic arrangement in crystals ammonium and potassium fluogermanates. T crystals possess one-molecule hexagonal units structure, and the crystal structure is an aggreg of univalent cations (K^+, NH_4^+) and nearly regu octahedral anions (GeF_6^{-2}) with Ge – F = 1·77 Each cation is surrounded by nine nearly equidist rine atoms and three others at somewhat greater tances. The structure is of the same general type that of the hexagonal modification of ammonium silicate; it is found only in the case of complex rides, for which at ordinary temperature it is ally preferred to the cubic ammonium chloro- tinate structural type.

ucture of Water in Ionic Solutions

HE effect of the presence of ions on the structure water molecules has long been the subject of estigation and discussion. In a recent article *Chem. Phys.*, 10, 869; 1939), G. W. Stewart orts data on the variation of the X-ray diffraction tern of water with concentration of dissolved ctrolytes (NH_4Cl, LiCl, NaCl, KCl, and $MgCl_2$), and ws the following direct conclusions from a con- ration of the displacements of the major and or diffraction peaks: (i) the increase in con- tration of ions causes the amount of 4-co-ordinated ter structure to decrease and produces a more sely-packed arrangement, with a consequent rease in density; (ii) the effect of the ion on the ter structure is not confined to that shell imme- tely adjacent to the ion; and (iii) the alteration structure is apparently similar to that produced by reasing the temperature of water. Further, from asurements on the alteration of the minor dif- ction peak by fifteen strong electrolytes, selected ause of their wide variation in type and in arent molal ionic volume, he shows that the liquid ucture of water varies with ionic concentration at ate comparable with the rate of variation of the arent molal ionic volume. It seems, in fact, that alteration in liquid structure has an effect on the arent molal ionic volume much more important n has the electrostatic effect based on the Debye- ckel theory. On the basis of these interesting data author draws a picture of the solvent and its ration in density by the ion solute which agrees h the conception of Bernal and Fowler (*ibid.*, 1, ; 1933). Water at temperatures just above the lting point has a co-ordination number greater than t in ice, and the packing is correspondingly closer the liquid. This difference explains the latent heat fusion, and the increase in density of water on lting. The structure of liquid water is not rigid, in a crystal, and the relation of any molecule to neighbours is constantly changing. Co-ordination ds are broken and re-made. The water is homo- eous only if a representative group of molecules is sidered. The effect of ions is not to contract the ucture but to increase the co-ordination number, l thus change the closeness of packing.

llar Structure and Stellar Energy

N interesting paper with the above title has been blished by W. H. McCrea (*Occas. Notes, Roy. Astro.* ., No. 6; October 1939). He gives a short summary the present position on attempts to utilize known ysical laws to explain the mechanism of energy- eration responsible for the maintenance of stellar inosity. The problem is to discover a mechanism energy-generation that will be consistent with the ysical conditions prevailing in the star. The blem of stellar structure can be stated in its erality as follows: given in some region of space quantity of matter of known chemical composition l given its initial physical state, what will be its sequent history? The problem would be soluble in principle if the physicist knew how the material components can interact with each other and with radiation, including the various ways in which the interaction could generate energy. The following points seem to be fairly well established. In the brighter stars of the main sequence, the energy-generation is provided by the formation of helium from hydrogen, and these stars have a large hydrogen content, their central temperatures being about 20 million degrees. While there is no evidence that the synthesis of heavier nuclei in stars occurs, it is certain that some of these nuclei have an essential role as catalysts in the synthesis of helium. Stars of the main sequence, the masses of which are not too great, ultimately contract and become white dwarfs. The giant stars present a difficulty if, as is predicted by the theory of stellar structure, they have relatively low central densities and temperatures. Gamow's suggestion of processes in which there is resonance between an energy level of a nucleus and the energy of a penetrating particle has not been substantiated, and it seems certain that there is an essential distinction between the structure or mode of energy-generation or both in the giants and main-sequence stars. Among the problems awaiting solution are the ultimate fate of massive stars, the mechanism of energy-production in giants, and the origin of heavier nuclei in stellar material.

Sunspots and Magnetic Disturbances

H. G. ARCHENHOLD has recently published a paper on the influence of the variability of the mean latitude of sunspots on the recurrence tendency of magnetic disturbances (*Mon. Not. Roy. Astro. Soc.*, 99, 9; October 1939). As is well known, the rotation of the sun varies with the latitude; also, the mean latitude of sunspots changes systematically during a sunspot cycle. In the first years, that is, after a sunspot minimum, the mean equator distance of the spots is about 20°, and at the end a little more than 5°. The synodic period of rotation corresponding to these latitudes is 27·5 and 26·9 days, respectively, and if terrestrial magnetic phenomena are connected with the areas of sunspots, there should be a sensible difference between the recurrence intervals in years of low and high sunspot latitudes. Chree and Stagg used the magnetic character figures of the years 1906–1925 and could not detect any effect in the case of terrestrial magnetism, but Archenhold has utilized data going back to 1847 and arrives at a different conclusion. As the data are not uniform, he found it necessary to employ different methods of analysis for different periods, and very full details are given of the procedure adopted. For all the groups dealt with he finds a recurrence interval of 27·02 days for the years before sunspot minima and of 27·52 days after the minima. The mean error of the first value is ±0·13 day, and that of the second is ±0·05 day. The difference of 0·5 day between the recurrence intervals in years before and after sunspot minima is thus 3·6 times the mean error, ±0·14 day. From the beginning of the cycle to the end, the recurrence interval shortens continually, and this is what would be expected because of the decrease in the mean equator distance of the sunspots. When sunspot zones occur near the equator and also in higher latitudes, the shorter recurrence interval of the equator belt prevails, because of the greater effectiveness of disturbed areas near to the equator on the earth's magnetism.

MEDAL AWARDS OF THE ROYAL SOCIETY*

Copley Medal

The Copley Medal has been awarded to Prof. Thomas Hunt Morgan.

The establishment of definite laws of heredity, and the discovery of the mechanism, the gene, by which hereditary qualities are carried on from generation to generation, has revolutionized our outlook on the function of the nucleus of the cell and of the chromosomes it contains; it has enabled us to understand the significance of the maturation of the germ cells and of fertilization as they occur in higher animals and plants, and thus led to a very rapid development of nuclear cytology. The theory of the gene has given us a new outlook on the determination of the development of an animal or plant. But nowhere has genetics produced greater changes than in our attitude to evolution. The observations that mutations arise *de novo* at a definite rate, that the number of different mutations occurring in a single species may be very large and that the mutations in allied species are essentially identical, have shown us for the first time the materials which are available as a basis for evolutionary change. The quantitative nature of genetics has made it possible to examine the effects which result after many generations from the establishment of a community by a few individuals of different hereditary composition, and to estimate the effect of a definite advantage attaching to one particular quality on the ultimate composition of a population. It has thus put the theory of natural selection on a sound theoretical basis. Furthermore, it has enabled us to observe indirectly the effects of natural selection in wild populations, and to plan experiments to determine its effects.

The practical applications of genetics are as important as its influence on theory. The whole of the breeding of many cultivated plants including maize is now firmly based, and the process of improvement immensely hastened by cytological examination. Genetics is already influencing animal breeding, and in its modern developments is throwing much light on the possibility of controlling hereditary diseases in man.

In the development of genetics, the work of the Morgan school has been paramount. It is to Morgan that we owe that exploitation of *Drosophila melanogaster*, which is the basis of most modern developments. To him we owe the theory of the gene, which is fundamental, and the explanation of 'crossing-over', which forms the basis of the conception of the linear arrangement of the genes and the chromosomes. From these starting points all other work springs, and much of this work comes from Morgan himself, his associates and his students. Morgan has done more than any other man to establish genetics and thus to revolutionize our ideas in many different fields of work, in practical affairs as in pure theory.

Royal Medals

A Royal Medal has been awarded to Prof. Paul Adrien Maurice Dirac.

Dirac's chief work has centred around the fundamental principles of modern theoretical physics. The
new quantum mechanics was discovered by Heis
berg in 1925. Dirac at once realized the great i
portance of this discovery, started to work out
fuller implications and by a remarkable combinati
of originality, mathematical skill and uncan
instinct, rapidly established himself as a great lea
in this field. His earliest efforts were directed
wards tidying up the intermediate field between tl
of the new quantum mechanics and the Newtoni
An early and very important paper was on
fundamental equations of quantum mechanics. T
was a generalization for which he introduced a n
algebra, that of non-commutative numbers.

Probably Dirac's greatest achievement was that
ending the conflict between quantum mechanics a
relativity mechanics by showing how to make
fundamental equations of quantum mechanics
variant under a Lorenz transformation, at any r
to a first approximation which has not yet be
improved on. This led to a revision of the theory
the hydrogen atom which confirmed Sommerfel
formula for the fine structures of spectrum lines a
X-ray levels. This formula had been derived hithe
from a mixture of empirical results and theoreti
guidance, but had not been deduced from gene
fundamental principles. The idea of a quanti
electron spin also fitted naturally into the n
theory. The harmonization of the quantum a
relativity mechanics also required the introducti
of the strange conception of negative energy sta
(holes) and this is generally regarded as a predict
of the existence of the positive electron (positr
since discovered by Anderson.

A Royal Medal has been awarded to Pr
David Keilin.

Prof. Keilin's contributions to entomology exte
over nearly thirty years. In the main they conce
the higher Diptera: with critical ability and a gr
capacity for detailed observation he has demonstrat
the very close correlation that exists between lar
structure and habits in these insects.

Prof. Keilin's main contributions to biochemis
have been his studies on the respiratory pigme
cytochrome, published in a series of papers fr
1925 onwards. He has shown that cytochrome
composed of at least four components related
hæmatin. One of these is in all probability
enzyme previously known as indophenoloxidase. T
catalytic activity of this enzyme depends entirely
co-operation with the other three components
cytochrome. The complete cytochrome system for
within the cell a highly active catalytic mechani
which by utilising molecular oxygen can easily oxid
hydrogen atoms of certain substrate molecules wh
have been activated by dehydrogenase syste
This shows that the enzyme component of cy
chrome may be identified with the previously und
covered oxygen-transporting enzyme of Warburg a
his co-workers.

Other work of Prof. Keilin in this field has includ
the characterization of certain oxidizing enzy
which make use of molecular oxygen, and the p
paration in a pure condition of the polyphe
oxidase of mushrooms. The latter has been sho
to be a copper protein compound. Recently he

o isolated in a pure state copper protein com- unds from blood corpuscles and liver (hæmo- prein and hepatocuprein), which may be of bio- ical importance though they are not apparently ncerned in oxidase reactions. Keilin has thus pro- led us with an integrated picture of cellular piration which is an enormous advance on the ich less systematized knowledge that we had fore his work was published.

DAVY MEDAL

The DAVY MEDAL has been awarded to Prof. MES WILLIAM MCBAIN.

McBain's claim to special recognition rests essen- lly on the circumstance that he created, and has the development of, a new and important chapter physical chemistry—the study of colloidal electro- es. It was as the result of a long series of precision asurements on the electrical and thermodynamic operties of soap solutions that McBain originally fined this new class of materials, which combine a special way the properties of colloids and ctrolytes. The definition and constitutional theory oved to be the key to the orderly exploration, ich thenceforth proceeded with continually grow- impetus, of a large and fruitful field—incidentally e of considerable technical importance. The terials include soaps, nearly all modern synthetic tergents, a number of inorganic substances such silicates and tellurates, as well as many dyes, oteins and bio-colloids.

In the continued investigation, in which numerous rkers have contributed to the general develop- nt of the subject, McBain has been a leader, and work has thrown much light not only on the cial properties of the ionic micelle, but also on the ysical properties of colloidal particles as a whole. the course of this work a great variety of experi- ntal methods has been developed—chemical, ctrical, optical and mechanical methods—which novel in their application and are in some cases vel in themselves. Reference may be made to the antitative study of 'solubilization' and the elabora- n of the air-borne ultracentrifuge in illustration of Bain's versatility of technique.

In addition to the composition and organization a colloidal particle, its interface with the con- uum has a decisive influence on its properties, and s gives special importance to the section of McBain's work which deals with the structure, composition and depth of macroscopic interfaces, especially of the surfaces of colloidal electrolyte solutions. Here also he has devised many methods of study, one of the most striking being the 'microtome' method whereby the outermost layer of a solution can be peeled off with a rapidly moving knife blade so that the surface concentration of solute can be directly determined.

HUGHES MEDAL

The HUGHES MEDAL has been awarded to Prof. GEORGE PAGET THOMSON.

Thomson's researches have been spread over a wide range of experimental and theoretical physics. Most of his earlier experiments were connected in some way or another with positive rays, and in this field he obtained a number of valuable results. Probably the most important of these is his discovery that the small-angle scattering of protons in hydrogen could not be accounted for by treating the protons and electrons as point charges obeying the inverse square law of force.

The scope of his work in pure physics is indicated by the titles of three books he has written or, in one case, helped to write. These are: "The Atom", "Wave Mechanics of the Free Electron" and the third edition of "Conduction of Electricity through Gases". The last is a joint effort with his father, and is the most important work there is on the subject. Within this range his work is both experimental and theoretical, but the experimental part predominates both in quantity and in importance.

Thomson has also made notable contributions to aeronautics. They include research work for the fighting air services during the War of 1914–18, a book entitled "Applied Aeronautics" (1919), and various contributions to Government publications.

Thomson's most distinguished work is based on Davisson's discovery—finally established in 1927—that electrons were reflected by single crystals as if they were possessed of the characteristics of waves. By brilliant experiments and able reasonings thereon, Thomson has opened out a new field of research which has been singularly fruitful and is still full of promise. He has been able to prove by direct experiment the correctness of Louis de Broglie's ideas of wave mechanics, not merely qualitatively but also quantitatively.

THE GREAT RED SPOT ON JUPITER

HE presidential address of the British Astron- omical Association was delivered on October 25 Mr. B. M. Peek, who took for his subject the ysical conditions of the planet Jupiter, and in rticular the red spot. It is certain that Schwabe's awings in 1831 showed this spot, and there is evidence at it was known from 1664, the date of Hooke's nous observation, until 1713, from which date a p of more than a century exists in the records. It is difficult to believe that a purely atmospheric enomenon could have continued so long without owing signs of dissipation, but the anomalies of its tion in longitude militate against the view that it arises from a centre of activity more deeply rooted than the atmosphere. It rotates nearly in accordance with system ii, that is, the system which represents approximately the period of features commonly seen outside the equatorial zone, 9h. 55m. 40·632s. An attempt was made by Peek to determine what system of uniform rotation most nearly represents the rotation of the spot from 1891 until 1931, but it is admitted that a simple mathematical expression to represent the motion is difficult to find, and the investigator is obliged to ask the question whether, in spite of its long persistence, the red spot is not a purely atmospheric phenomenon. At this stage of the inquiry it is necessary to define the term 'atmosphere'.

Both Wildt and Peek have shown that beyond a depth of 100 km. the atmosphere of Jupiter must be compressed to the density of the liquid or solid state of the substances composing it. It is possible to conceive of this atmosphere as composed of highly condensed permanent gases, and at greater depths these gases may be solidified. The temperature of the surface of such an atmosphere would probably be in the neighbourhood of 150° K. (– 123° C.), and from the dry adiabatic lapse-rate at the surface of Jupiter it is certain that the temperature must increase rapidly with the depth for the first few kilometres. When, however, the gas laws break down, it is probable that practically isothermal conditions prevail and the isotherm may be about 300° K. Jeffreys' investigations suggest that a thick layer composed of one of Bridgman's high-pressure modification of ice, probably ice vii, lies underneath, and Peek considers the case of an enormous berg, towering above the general level of the layer. Would the viscosity of the ice allow it to drift in longitude like the red spot?

Mr. Peek then develops a suggestion made by Wildt[1] that the spot may be a solid body floating in an 'ocean of permanent gases', and proposes following tentative hypothesis: A solid body which is provisionally called ice, floats in a perman gas *B*, provisionally called nitrogen. If the forn is ice vii, it may be supposed that a small port near the top would gradually change its phase fr ice vii to ice vi, and, owing to the absorption heat, the atmosphere above it would be cooled. T red spot is, it is thought, "a manifestation at visible surface of the thermal effects accompany the change of phase".

Assuming further that the level at which the floats is subject to small variations, the radius gyration about the axis of the planet will vary, a a simple calculation shows that a total range of 10 k would account for all the changes in velocity t the red spot has undergone during the period investigation. While ice and nitrogen illustrate v readily the hypothesis, it is pointed out that phase diagrams of other substances, such as hydro and helium, also suggest suitable conditions, and is unnecessary to assume that ice and nitrogen actually responsible for the phenomenon. It is ho that the matter will be investigated more fully the near future.

---

[1] *Proc. Amer. Phil. Soc.*, 81, 1 (1939).

POSSIBILITIES OF ALTERNATING CURRENTS FOR LONG-DISTANCE TRANSMISSION

IN the *Electrical Review* of October 20, H. Rissik shows that some of our early notions about the transmission of electric power must be modified. In the past no difficulty was at first experienced in utilizing the line conductors to the full extent of their carrying capacity. Transmission distances were short and the power to be transmitted amounted to only a few thousand kilowatts. As time went on and transmission voltages and distances gradually increased, the view became common that any technical limitation to the amount of power that could be transmitted was to be looked for in the nature of the generating plant and transformers, rather than in those of the transmission line itself. It was seen that there was no longer a definite line voltage for a given power and distance giving the lowest transmission costs, which diminished as the voltage that could be used increased. Other characteristics of the electric plant had to be taken into account.

The special problems created by the linking up of immense power networks operating at 132 and 154 kv. and in many cases at 220 kv., involving power interchange over long distances, first became acute in the United States, and they have also arisen in France, Germany and the U.S.S.R. To the pioneer work of American engineers we are indebted for our present knowledge of the essential factors which contribute to system instability. They have also developed methods of improving the stable operation of power systems. It is very creditable that individual electricity undertakings, operating on a very large scale, should have deliberately subjected their power systems to major electrical disturbances in order to verify calculations based upon a new theory. This form of large-scale experimentation was on several occasions undertaken in the United Sta notably in 1928 on the 220 kv. system of the South California Edison Co. and again in 1930 on 132 kv. system of the West Penn Electric Co.

As a result of the experience accumulated dur the last ten years, it has become possible to investig technically methods whereby the stability of sup power trunk lines may be raised to levels wh economics once more becomes the decisive fact It has been for a long time common practice employ a synchronous condenser at the load end a transmission line in order to maintain the termi voltage common at all loads. In 1921 Baum show that this principle could be extended to a long l divided into several sections and having synchron condenser stations located at the points of secti Taken as a whole this transmission line acquires electrical characteristics of its individual sectio As the result of the reactive power compensat effected by the intermediate condenser stations, voltage at each point of section is maintained c stant and equal to the transmission pressure.

Another system is the self-tuned line. To ev frequency of alternating current there correspond wave-length, such that their product equals velocity of propagation of the train of electric wa just as in radio, television and carrier communicat For overhead lines, the velocity of propagation approximately equal to the velocity of light, that about 180,000 miles per second, so that the wa length of a 50-cycle transmission line would be ab 3,700 miles. Skilling showed in 1927 that if transmission distance is just half the wave-lengt the applied frequency, the line inductance and cap ity cancel each other out and the line beha tually as if it possessed resistance only. Such a constitutes a tuned circuit which resonates at frequency of the applied voltage. It would be icult to realize this in practice as at the normal quency of 50 the transmission distance would have be 1,850 miles. This limitation of great length ld be got over by the 'compensated line' system, ere a series excitation scheme is artificially loaded h series capacitance. One successful application of method was from a substation of the New York Power and Light Corporation at 33 kv. installed in 1928. The chief disadvantages of using large static condensers is their expense and their liability to damage by over-voltage.

Another possible method would be to load the line at intervals with shunt reactors, after the manner of the Pupin loading coils used in telephony, over underground cables. Such a dual compensated line would behave as if it possessed resistance only.

OPERATION AND DESIGN OF TROLLEYBUSES

PAPER by G. F. Sinclair, of the London Passenger Transport Board, on the trolley- system was published by the Institution of ctrical Engineers on November 9. The trolleybus been adjudged by the Ministry of Transport an ctric vehicle, and its construction and operation governed by the Ministry's regulations. These w the vehicles to be built one ton heavier than er forms of road passenger vehicle. They can be igned with large seating capacities with accommo- ion up to seventy passengers.

The cost of maintaining a 70-seater trolleybus is greater than that of the much smaller unit, the sel bus. On a mileage basis the capital charges the vehicles, taken over a period of twelve years, uming similar seating capacities, show little ference when the two types are compared. The rage energy consumption for trolleybuses operating an intensive service is approximately 2·75 units car mile, measured at the substation. The price direct-current energy varies from 0·5*d*. to 0·8*d*. unit. At the higher figure the cost per ton-mile high compared with the Diesel bus, but at 0·5*d*. unit the comparison is favourable to the trolley- s. For passenger services in densely populated as, the vehicle with comparable costs, which can form the cycle of starting and stopping to pick and set down the greatest number of fare-paying sengers in the least time, will produce economies. e high acceleration of the trolleybus due to the erload capacity of its motor gives the facility for erating high schedule speeds. The ability to mar- l vehicles in different areas is also a great con- nience. In the everyday movement of the people the road to and from their work, the use of non- p vehicles plays little part. The travelling public ve shown their appreciation of the comfort in vel, the fine riding qualities and quiet operation these vehicles. The residential population and siness people on the routes served by trolleybuses ve greatly benefited from their smooth and quiet ning.

Among the many points interesting to all elec- cians touched on by Mr. Sinclair is the production electric charges on trolleybuses, and the methods suppressing the interference with radio trans- sion signals, whether of sound or vision broad- ts. In service, the electric charges may be duced by the friction of the tyres on the road face, by the rise of potential due to the inductive k from the contactor coils, possibly by the mutual luction from the currents in the transmission mains, lastly when a leakage occurs from the power cir- its to the body of the car. It has to be remembered t it is only in very special circumstances that these conditions can arise. In any event they present little inconvenience to the travelling public. Consider a rubber-tyred vehicle with a metal or composite body; the generation of a charge depends largely on the road surface. With dry clean granite sets, voltages up to 900 can be measured by an electrostatic voltmeter immediately after the vehicle comes to rest. If the roads are asphalt or tar-macadam, only zero readings will be obtained. When the circuits of the electrical equipment are broken, the inductive charges may give voltages up to 300. Neither of these types of charges necessitates special precautions, as the frequency of loading or unloading passengers prevents high static charges from being built up. The use of 'low resistance' tyres, of about 2,000 ohms measured from the tread to the wheel rim, provides satisfactorily for earthing these charges.

It is the possibility of electrical leakage from the 600-volt circuits which has to be guarded against—the vehicle being in reality unearthed. The Ministry of Transport regulations require a daily test of the insulation of each trolleybus. The test is carried out after the vehicle has completed each day's service. Testing apparatus is located at the entrance of the depots. This enables the test to be carried out with the trolleybus in the condition in which it has been operating, an especially important point in wet or snowy weather, as the insulation resistance varies largely with the climatic conditions. For convenience in testing, the frames of the individual 600-volt units are connected by means of cables to a common testing receptacle, which is mounted at the back of the trolleybus underneath the platform. The nightly test is between the conductors and the body or chassis, the secondary insulation being short-circuited. Every fourteen days, each high-voltage circuit is tested individually, including all insulation whether primary or secondary. The insulation of the platform consists of a rubber mat secured to the floor boarding by an adhesive. The handrails have an insulated covering and are provided with secondary insulation, the combined arrangement giving insulation readings of 'infinity'.

The British Standards Institution has recently published a specification setting out the three methods used for reducing the electrical interference with radio broadcasting, etc., generated by the trolleybus equipment. The results of large-scale experiments carried out in London for preventing interference by trolleybuses are described.

On a fleet of more than 1,600 trolleybuses in London, the use of carbon 'shoes' to collect the current from the overhead wires is general. The success of the carbon collectors is due largely to the lubrication of the conductors.

SCIENCE NEWS A CENTURY AGO

Travels in Eastern Turkey

AT a meeting of the Geographical Society on December 9, 1839, a communication was read from Mr. John Brant, H.M. Consul at Erzurum, describing a tour of about 900 miles in the country lying to the south of Mount Ararat and the north of the River Tigris. Brant was accompanied by Dr. E. D. Dickson and A. G. Glascott, R.N., who had mapped the route followed and had also prepared a chart of a section of the high land of Armenia, between Trebizon on the Black Sea, and Mosul on the Tigris, a direct distance of 360 miles, showing the remarkable features of the elevated plateau, which for the greater part preserves a level of 6,000 ft. above the sea. Astronomical positions were determined of the principal places visited, resulting in the correction of many errors. Among the towns visited was that of Van on the east side of the lake of that name. The town had a population of about 35,000, half of whom were Armenians. The lake covers about 900 square miles and is 5,470 ft. above the level of the sea. By a special order of the Pasha, the party were able to visit the castle and caves and they also inspected the cuneiform inscriptions near Van, the Pasha expressing great anxiety to know if the party could translate them. An expedition was also made to the top of the mountain of Supan Tagla, 4,000 ft. above the lake and 9,500 ft. above sea-level, the theodolite being placed on the summit. From this spot could be seen to the north-east the beautiful peaks of the Great and Lesser Ararat, at a distance of 80 miles, rising into the regions of eternal snow.

Electro-deposition of Copper

"CONSIDERABLE interest has been excited in the scientific world," said the *Athenæum* of December 14, 1839, "by Mr. Spencer's new process of copying medals and other works of art, in copper, by the agency of voltaic electricity. It is with great pleasure we hear that this process is already beginning to be employed in certain of our manufactures, and that thus electricity will soon be numbered among the agents employed for practical and useful purposes. . . . In the manufacture of plated articles and ornaments it is often desirable to copy ornamental work, such as leaves, flowers and arabesque mouldings; this is both difficult and expensive, and from these causes often impossible. Mr. Spencer's invention, however, affords a cheap and easy method of performing what is required, and thus, ornaments on rich ancient plate are copied with the greatest perfection and ease, and without injury to the original. The great advantage consisting in the means of obtaining at very small expense, a facsimile in copper of the ornaments required to be copied, which may then be silvered or gilt. . . . The casts of medals, transmitted to us by Mr. Spencer, and also those made by Mr. E. Solly and Mr. J. Newman, and exhibited lately at the meeting of the Society of Arts, were very pure and compact copper, and the surface was as brilliant and perfect as could be desired. The process, indeed, is simple, and so far from its requiring, as is generally supposed, either expensive and complicated apparatus, or deep scientific knowledge, nothing can be more easy, as the observance of a few rules renders the success of the process quite certain, and, as regards the expense of the apparatus, the whole of it may be acquired for a few pence."

UNIVERSITY EVENTS

CAMBRIDGE.—During the vacancy in the profes ship of chemistry, Dr. H. McCombie will be tempo director of the laboratory of general and org chemistry—that is to say, all those parts of chemical laboratory not at present assigned for use of the professors of colloid science, theoret chemistry, metallurgy, and physical chemistry.

In accordance with its usual practice, Tri College, Cambridge, announces the offer of a search studentship open to graduates of other versities who propose to go to Cambridge in Octo next as candidates for the degree of Ph.D. The va of the studentship may be as much as £300 a yea the pecuniary circumstances of the successful c didate require so large a sum. Candidates must have reached the age of twenty-six before May 1. certain circumstances an election may be made an additional studentship. The same College off as usual, Dominion and Colonial exhibitions students of Dominion and Colonial universities wish to go to Cambridge next October as candid for the degree of B.A., M.Litt., M.Sc., or Ph These exhibitions are of the titular value of £ but their actual value is fixed by the College Cou in accordance with the exhibitioner's financial cumstances. A candidate for a studentship or e bition should apply through the principal autho of his university, and his application should re the Senior Tutor of Trinity College (from wh further particulars may be obtained) by May 1, 19

OXFORD.—H. G. Champion, New College, has b appointed to the professorship of forestry, vaca by the death of Prof. R. S. Troup, as from Tri Term, 1940.

Miss A. Pellew, St. Hugh's College, has b awarded the Edgell Sheppee Scholarship in engin ing science.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments o before the dates mentioned:

UNIVERSITY GRADUATES as Teachers of English for Colom British Council, 3 Hanover Street, W.1. (December 15, qu 'Colombia').

SENIOR EXPERIMENTAL OFFICERS (Male), EXPERIMENTAL OFFI (Male), and EXPERIMENTAL ASSISTANTS (Male and Female) by Ministry of Supply—The Ministry of Supply (S.B.3), The Ade W.C.2 (December 20, quoting Appts 015/S.B.3).

WOMAN PROFESSOR IN CHEMISTRY at the Huguenot Unive College, Wellington, Cape—The Secretary, Office of the High (missioner for the Union of South Africa, South Africa Ho Trafalgar Square, W.C.2 (December 31).

THE PRESSURE OF POPULATION

HE word 'science' normally connotes physical and chemical science to the public mind and lay press, to whom biological science is part nedicine, and it is not realized that there is also ience of world affairs and economic problems. if the problems of peace, already beginning to gitated, are not this time solved largely in a ntific manner instead of being left to politi- s and international financiers, the result will no better than the unsuccessful attempt at a world which came into being after the ill- d Treaty of Versailles.

ost of the immediate problems arise as the lt of pressure of population, a phrase which fficiently elastic to extend to many problems, of them capable of scientific analysis. One mn of the daily newspaper informs us of number of unemployed in Great Britain in the United States, whilst in another e are statements in regard to the inevitable sequences of the fall in the birth-rate. The rage citizen cannot make up his mind whether e are too many or too few people in England. is at least aware of the economic conditions ch make him unable to afford a larger family self if he has to feed and clothe and educate m ; he also knows that the absence of domestic is another factor against the larger family. cannot understand either, why there should be ample work and a livelihood for a larger ulation in Canada, where there has been so ch unemployment. In the end, he asks the stion, whether there are too many people or fficient capital ?

his is a question which merits the attention of man of science. There are many methods of roach to its study, one of which is the historical. Something may be learned by a comparison of the state of development in England at the end of the eighteenth century and that existing to-day in the Balkan countries.

There was then a population surplus in England ; indeed it was in 1798 that Malthus published his famous essay and predicted a sorry fate for mankind, which he pictured as growing faster than the food supply. Sir William Crookes was equally concerned about the food situation in his now famous address to the British Association at Bristol, only a year or two before the chemists learned how to make nitrates from the air and so put an end to any fear of food shortage. To-day the world can produce such an excess of the staple foods that their value, as the result of competition, shows no profit to the grower over the cost of production.

Statistics indicate a population of about 60 inhabitants per square kilometre for England and Wales in 1800, whereas, according to Prof. Ernst Wagemann, who has recently published (in German) a most exhaustive study of this question, that of the Balkan Peninsula to-day is about 62 ("Der Neue Balkan", Hamburg, 1939).

In 1800 conditions were very bad in England. Bad harvests, the ill effects of war, financial and trade disturbances brought the country near to famine and the brink of ruin. Large land holdings and pasturing were spreading and exerting pressure on the peasantry. There existed an ever-increasing agricultural population surplus which had to be cared for by somebody. In the Balkans this surplus exists to-day. The relative figures are significant. Only 63 per cent of the actual labour supply is being used ; in Bulgaria at least 750,000 men could be withdrawn from agriculture without injuring production. Some 114 persons are employed per 100 hectares of cultivated land against 50 in France and Germany, 17 in the United States. Life is said to be quite comfortable for the peasants who own their own farms.

The population density figure of 60 is small compared with highly industrialized countries; in Belgium it is more than 200, and it is clear that the Balkans are over-populated only in relation to their economic and technical development. As Wagemann puts it, they are "under-technicalized" rather than "under-capitalized".

It is desirable to stress the implication to Britain and British industry of this conception of countries with "too many people". It has long been the policy of Great Britain to expect the world, and her Dominions and colonies in particular, to produce foodstuffs and raw or quasi-manufactured materials, and to leave to Britain the elaboration of these in her technical industries. There are to-day "too many people" in several parts of the world and the belief is gaining ground that only by "technicalization", that is, by becoming industrial, can a balance be effected. In the British Empire we have perhaps opposed the trend too long; the Dominions at least are resolute in their intention to establish industries. It is true that their products cannot compete for cost and even for quality with those produced at home on a large scale and with long experience, but the Australian is prepared to put up with this and to tax English products to make them competitive in order to have work for his people.

The industrial apparatus of the world is already over-developed, and the older countries were, before the war, meeting with difficulties in selling their goods. Indeed it is clear that the solution of the over-population problem is to be sought least of all in the establishment of highly technical 'machine industries'.

The greatest possibilities in the Balkan countries lie in the introduction of crops which require intensive labour for their cultivation, such as tobacco, flax, hemp, rape seed, soya beans, etc., vegetables and fruit which are either easy to export or can serve as raw materials for domestic industries. Further, stable-feeding of stock can be substituted for pasture feeding. Humidity and fertility would permit much to be done in the above directions as the climate is favourable: irrigation and rational farming are claimed to make it possible to double the employment on the land and the yield per hectare in south-east Europe.

Such a change would take many years to fect, but it would largely solve the Balkan po lation problem and at the same time cause a gr increase in the purchasing power of the farm which in turn would react on the industries of countries.

The low intellectual level of the population n be measured by the small consumption of pap less than 10 per cent of that in Germany, wh in turn was much less than it is in the Uni States. The peasants hoard their money, custom which still more restricts the amount capital available for development.

It is not always realized how employment adversely affected even in England by the v great difficulty experienced in getting money new enterprises and new factories, especially o modest scale. The complexity and cost of mod machinery and the regulations of the Factory make it almost impossible to start from sm beginnings as in the past. Sooner or later a meth of solving these financial problems of the sm manufacturer will have to be discovered.

Here also there has been a tendency both on part of banks and individuals to sterilize cre by placing money on deposit. The Governm has been forced to finance much of the cap work of rearmament, and we are undoubtedly consequence advancing towards the nationalizat of capital. The pressure of population can o be met by the existence of enough credit provide new enterprises.

There is much talk of freedom but very littl responsibility, of which we are only just becom conscious. Democracy has "a responsibility guide, to understand, to upbuild and to mak world of the twenty-first century" in the wo recently used by Dr. Nicholas Murray But Each one of us has a part to play, a responsibili the one to invent new processes, a second carry them out, a third to do the manual worl fourth to find the capital moneys for their ins lation, a fifth to bring the products to the pul The chain is a continuous one, the links are equal strength; if anyone fails to do his sh there will be failure of the whole, and his is responsibility. There need not be "too m people" if the responsibility is accepted: all c cerned will have to work together much m than they have in the past. This must be d willingly and not under compulsion.

GROWTH OF THE KINETIC THEORY

e Mathematical Theory of Non-Uniform
ses
Account of the Kinetic Theory of Viscosity,
ermal Conduction, and Diffusion in Gases. By
of. Sydney Chapman and Dr. T. G. Cowling.
. xxiii + 404. (Cambridge: At the University
ess, 1939.) 30s. net.

INCE the days when the kinetic theory of gases was founded by Clausius, Maxwell and ltzmann, great changes have taken place in the pe and bearing of the descendent theory. king a wide view of its present field, the quali- ation "of gases" has become a misnomer. One n see that the ultimate scope of the descendent the kinetic theory of gases must be the whole ld of the properties of matter in bulk, derived m the atomic constitution of matter and from properties of atoms and their interactions. e present scope of the theory falls short of such lusiveness, but not so far short as to leave any ubts for the future.

The old kinetic theory of gases has thus de- loped into the 'atomic theory of the properties matter in bulk'. In so doing it has bifurcated arply into (1) the theory of the properties of atter in equilibrium, and (2) the theory of nsport phenomena and other rates of change, h as chemical kinetics. The first branch is mmonly called, perhaps rather unfortunately, atistical Mechanics. It has grown out of elaborate d repeated rediscussions of Maxwell's two early orems (1859), his distribution law for the lecular velocities of a gas in equilibrium, and law of equipartition of energy among two sets molecules in a gas mixture (the latter a redis- very of a result of Waterston (1845)). The imary result of these rediscussions has been to w that the results do not depend on any cial molecular properties, and so that the uilibrium state in question is independent of the chanisms by which it is set up and preserved. us the field of statistical mechanics is coterm- us with that of thermodynamics, and has entially the same generality. For the same son, statistical mechanics has proved far the ier branch in which to make rapid progress. In t, progress has been so rapid that one may rly say that the complete outline of statistical chanics (the atomic theory of the properties matter in equilibrium), including a rational rivation therefrom of thermodynamics, was tched by Gibbs in 1901 in his "Elementary Principles in Statistical Mechanics". Advances since then have, quite literally, only been concerned with rewriting Gibbs's theory in terms of the quantum theory, and with filling in the details by special applications.

The second branch from the old stem, the theory of transport phenomena, has proved far more difficult to climb. In the nature of things, one must expect that it will be easier to determine a limit than the rate of approach to that limit. The rate, moreover, will necessarily depend on details of the mechanisms of interaction among the many systems concerned. Transport phenomena and other rates of change have been studied profoundly for all states of matter, but a great part of these studies cannot properly be classed as part of an atomic theory of the properties of matter in bulk. Phenomenological theories, of heat conduction, for example, in which a successful description is given in terms of an assumed coefficient (the conductivity), do not qualify for inclusion, since the essential feature of an atomic theory is the *a priori* evaluation of this coefficient in terms of atomic properties. Much progress in the genuine atomic theory of transport phenomena has nevertheless been made, since Maxwell's paper "On the Dynamical Theory of Gases" (1866) first formulated rigorously the discussion of a non-uniform gas. Such genuine progress has not been confined to the gaseous state or to classical transport phenomena (diffusion, viscosity, heat conduction). It is only necessary to recall the subject of chemical kinetics, which has made much progress in the gaseous, liquid and even the solid state. The mathematical difficulties, however, are very great; it is only in the atomic theory of transport phenomena in almost perfect gases (which includes, as it happens, the electronic theory of metallic conduction) that progress has been sufficiently outstanding for the theory to have achieved any appreciable perfection of mathematical form. Along this one spray of the branch, however, complete success has been reached. It is the definitive mathematical theory of atomic transport phenomena in almost perfect gases that is recorded in the book under review, in a perfection of form which is unlikely to be seriously bettered for a long time.

The stages by which this success has been achieved are recorded by Chapman and Cowling in a most interesting historical note at the end of the book. In 1866 Maxwell was able to obtain the first accurate results for the coefficients of heat conductivity and viscosity of a gas by confining himself to molecules which interact like point centres of force repelling according to the inverse fifth power of the distance (Maxwellian molecules). For this particular model it so happens that all the integrations over the circumstances of a molecular encounter can be carried out without a knowledge of the manner in which the molecular distribution law $f(u, v, w)$ deviates from place to place in the non-uniform gas from its Maxwellian value for a uniform gas. In all other cases, a knowledge of the distorted $f(u, v, w)$ is required, and this must be provided by solving the famous integro-differential equation of Boltzmann, first formulated in 1872, or by some equivalent procedure. There matters rested until 1905, when Lorentz solved Boltzmann's equation in the special simple case required for the discussion of the thermal and electrical conductivities of a metal, treated classically. The successful treatment of this special case gave no indication, however, of how to proceed in even the simplest case applicable to an ordinary (non-Maxwellian) gas. It was not until the independent investigations of Enskog and Chapman, 1911–17, that Boltzmann's integro-differential equation for a gas was solved, and the coefficients of diffusion, viscosity and heat conduction for a gas calculated from a proper atomic model conforming to other atomic requirements. The interesting new feature of thermal diffusion (for non-Maxwellian gases) was discovered theoretically by Enskog in 1911, re-derived by Chapman in 1916, and then confirmed experimentally by Dootson. Since then a probably final polish has been given to the theory in 1935 by Burnett, who has found that the correct form of expansion to use in solving Boltzmann's equation is one in terms of Sonine polynomials.

In the body of the book this final form of the mathematical theory is presented at length and applied to actual gases. It is presented in a rather unusual vector and tensor notation described in Chapter i. This makes the following exposition somewhat severe reading, unless the reader first thoroughly masters and familiarizes himself with the notation. A powerful and compact notation is, however, essential to an elegant presentation of the many vital complicated formulæ, and the authors' novel notation appears to be most successful and completely justified.

After a preliminary description of the properties of a gas, the equations of transfer of Maxwell and the integro-differential equation of Boltzmann are derived in a general form on the assumption of molecular chaos, followed by a deduction therefrom of the equilibrium properties of a gas. Further comments on the assumption of molecular chaos will be made at the close of this review. In two short chapters transport phenomena are th
discussed on the basis of the idea of a mean f
path, and the weakness of this method poin
out. The main body of the book (Chapters vii
inclusive) then follows, giving the complete mat
matical deduction of the coefficients for diffusi
thermal diffusion, viscosity and heat conductiv
for simple gases and gaseous mixtures at su
densities that the mean free paths are long co
pared with the molecular dimensions, and negle
ing any quantal effects. An exposition of t
classical theory has long been required;
exposition of such elegance and authority w
worth an even longer wait, and this section, wh
is the kernel of the book, forms a notable additi
to the literature of theoretical atomic physics.

The remaining sections of the book conta
moreover, important additions to the cent
theme. Chapter xvii gives an excellent accou
of the modifications introduced into the theory
transport phenomena by the quantum theo
including a sketch of the electron theory of meta
so far as the transport phenomena involved c
be described in terms of a mean free path (So
merfeld's approximation). Chapter xviii gives t
necessary extension of the theory to the case o
gas of ions subject to electric and magnetic fiel
This is followed by two valuable mathemati
appendixes. There remains to be mentioned or
one further section, Chapter xvi on dense gas
which is to my mind the one section of dubio
value, and certainly not of the classical standa
of permanence achieved in all other sections
the book. The idea of the discussion is to inclu
the effect of collisions in transferring energy a
momentum instantaneously through a distance
one molecular diameter, an effect which is ad
tional to molecular transport over the mean fr
path. The effect naturally exists, but I cann
believe that it plays an important part in modifyi
the viscosity of ordinary gases to that of den
gases and liquids, though it may of course ha
a sensible effect in the first changes as the densi
increases. As presented here, I feel that t
quality of Chapter xvi and its lack of generali
make it rather out of place among the classic
perfection of the rest of the book.

The contemplation of the theory here expound
invites some further not very profound reflectio
on cognate matters of theoretical atomic physi
In the first place, one notices at once that t
atomic theory of transport here given, which is
first sight theoretically complete, excludes in fa
all such interesting forms of transport as turbulen
in boundary layers, heat convection, and ed
viscosity and conductivity on the larger sca
found in the atmosphere and in tidal currents.
is easy to see that they are in effect excluded fro

e theory by the assumption of molecular chaos which the whole atomic theory of transport is nstructed. The next step for a wider atomic eory in which turbulent effects in general can ve their proper place must be to discard, or ther to modify, this assumption—a theoretical vance which, if it could be made successfully, ould lead to results of outstanding importance.

A conclusion of general interest can be drawn m a study of this atomic transport theory and rticularly from a comparison of its exact results th those of the approximate version using mean e paths, a version which effectively also ignores y change in the form of the distribution function , v, w). Having here the exact solution, one ows that an approximate discussion, using , v, w) without modification, is liable to make ors in the numerical coefficients by factors of out 2, although it gives results of the correct neral form. One may safely conclude from this at errors of similar magnitude are liable to cur when a similar use is made of unmodified uilibrium theory in the study of other rates of ange such as chemical kinetics. One can thus tain a reliable warning against too complete a st in approximations of this type, which are herwise impossible to check in the absence of an act theory.

My final reflection concerns the bearing of the atomic transport theory on the possibility of a very general type of extension of statistical mechanics—a possibility in which it is very tempting to indulge unduly optimistic hopes. Contemplating the general results of equilibrium theory, which may be expressed so simply by saying that the equilibrium state of a system is the state of the system of maximum probability subject to certain boundary conditions, such as given volume and given energy, one argues, why should not a non-equilibrium state be derivable almost as simply as a state of maximum probability subject to somewhat different boundary conditions, including, for example, in a conduction problem a condition of given flow of heat. The effective answer seems to me to be provided by the results of the atomic transport theory. Here we know the correct answer to the conduction problem; its dependence on atomic properties is so complex that one can scarcely believe that it can be derivable by any process much less profound than Chapman's or Enskog's analysis. The answer this analysis gives may be in fact a condition of maximum probability for certain given boundary conditions, but that by starting from this condition one can arrive at the correct result in any simple way appears to me most unlikely. To attempt to do so would be to pursue a will o' the wisp.

R. H. FOWLER.

STUDIES OF OLD AGE

oblems of Ageing
ological and Medical Aspects. Edited by E. V. wdry. (A publication of the Josiah Macy, Jr., undation.) Pp. xxx + 758. (London: Baillière, ndall and Cox, 1939.) 45s.

THIS volume on the process of ageing has been sponsored by the Josiah Macy Founda- n in continuance of its interest in degenerative seases and in the hope of focussing attention on a problem which has far-reaching scientific d social implications for a society with a rapidly creasing proportion of older men and women." runs the introduction to a volume of a new aracter.

In our generation we have not yet thoroughly preciated all the problems involved in the crease in the gerontocrasy, due to improved alth and other factors. Is old age a blessing? is volume is written by a group of experts and tempts to deal with the whole range of problems ecting old age. The contributors are E. Allen, L. B. Barker, W. B. Cannon, A. J. Carlson. A. E. Cohn, E. V. Cowdry, M. Critchley, W. Crocker, J. Dewey, L. I. Dublin, E. T. Engle, J. S. Friedenwald, S. R. Guild, G. V. Hamilton, L. O. Howard, A. C. Ivy, H. S. Jennings, E. B. Krumbhaer, K. Landsteiner, C. M. McCay, W. MacNider, W. R. Miles, J. Oliver, T. W. Todd, F. D. Wiedman, and C. Wissler.

Starting with chapters dealing with the ageing of plants, in which we learn that trees may live as long as 7,000 years, the book works through Protozoa and insects to vertebrates and man, dealing not only with longevity records but also with more psychological questions such as human cultural levels.

Some chapters follow upon various tissues of the body in detail, such as skin, the endocrines and the reproductive systems. Last come discussions of a more general nature, among which we may mention change in personality with age, and seniority from a clinician's point of view.

As may be expected, there is some unevenness in treatment, but the editor has been successful in keeping this to a minimum, and producing a readable continuum. It is invidious to select from such a work, but mention may be made especially of the section upon chemical aspects of growth, in which among other chemical points, a reference is made to the startling experiments which have shown that the life-span of rats may be altered by diet. In a generation when all eyes are turned towards the attempt to impr rapidity of growth, it is revolutionary to ha observations which hint that such speed may be good for longevity.

The level of writing is high and there is mu information presented, so that the book necessar forms a standard work of reference. The print must be congratulated upon an excellent standa of production.

CHEMISTRY OF CHEMICAL WARFARE

The War Gases

Chemistry and Analysis. By Dr. Mario Sartori. Translated from the second enlarged Italian edition by L. W. Marrison. Pp. xii + 360. (London: J. and A. Churchill, Ltd., 1939.) 21*s*.

THE first Italian edition of this work was published in 1933, and in 1935 there appeared a German translation by Dr. Klumb which was reviewed in NATURE of April 11, 1936, p. 598. A considerable number of books on gas warfare have been written in the last twenty years, but they mostly deal with its military and medical aspects and give comparatively little information about the chemistry of war gases. Dr. Sartori, on the contrary, confines his attention mostly to the chemistry of these substances, but also deals briefly with some of their other properties.

In this second edition, the author has introduced a few pages on the physiopathological properties, and then has dealt in a general way with the physical properties, especially the vapour tension and the related properties: volatility, boiling point and persistence. The volatility is defined as the weight of the substance contained in a cubic metre of saturated vapour at a certain temperature. Consequently, it must be proportional to the product of the vapour tension and the molecular weight. On pp. 6 and 7, however, there are tables of the vapour tension and volatility respectively, and it is evident that the figures are not proportional, even when allowance is made for the differences in molecular weight. At the end of the book there is a more extensive table in which these two properties are given in adjacent columns, and the same discrepancy appears again. Apparently, some of these volatilities were calculated from values for the vapour pressure very different from those given both in the tables and in other parts of the book. It is remarkable that this fairly obvious error has been repeated from the first to the second Italian edition, and has not been noticed by either the German or the English translator. There is a similar discrepancy in t persistences of dichloroethyl sulphide (must gas) and bromobenzyl cyanide (*CA*) as given the table on p. 11.

In the last line of the last table on the last pa of the text the molecular weight of phenarsazi cyanide, $NH(C_6H_4)_2AsCN$, is given as 27 whereas the German edition gave it as 27 The correct figure is 268.

Numerous additions have been made in t second edition; the substances dealt with ha increased from forty-nine to sixty-four, but t additional fifteen war gases do not appear to of much practical value and have evidently be introduced to make the work more complete. is not to be expected that important new develo ments will be published at present. After t War of 1914–18 much of the accumulated inform tion was released, but the international tensi during recent years has led to a return to secre It is also improbable that much advance, if it can called advance, has been made by the vario chemical 'defence' research institutions, as th is no satisfactory method of testing these poiso They cannot be tried on human beings except mild doses, and the results with animals may quite different. The Germans published the resu of tests with cats, and more recently the America have released some results with dogs and mice. might be expected, the results do not run parall

There is a good deal of additional informati in this edition, and there must now be about thousand references to original papers. The bo is evidently the result of years of work and v be found an indispensable guide through t scattered literature of the subject in spite of so inaccuracies in the numerical data. For ea substance the available information is given the properties, laboratory preparation, man facture and analysis. The translation has be well carried out and the get-up is good, as it to be expected from the firm of Churchill.

ARTHUR MARSHALL.

RESPIRATORY ENZYMES

espiratory Enzymes
y University of Wisconsin Biochemists, under
e direction of C. A. Elvehjem and P. W. Wilson.
p. v + 236. (Minneapolis: Burgess Publishing
o., 1939.) 3.25 dollars.

THE rapid developments during recent years in our knowledge of respiratory enzyme ystems have created a demand for a book which, hilst giving an accurate and coherent account of ese developments, indicates the nature of the exerimental work leading up to them and shows the anner in which they are interrelated. Much of he relevant information which has been summarized so far, is to be found in authoritative but omewhat scattered review articles. It would bviously be a convenience to the student and o the experimental worker to have at hand a easonably accurate account of the present state f the subject, in which sufficient of the older ork is discussed to provide a proper perspective r the appreciation of the value of recent contributions.

The volume under review presents such a summary. It consists of a series of articles, reproduced from typescript, bearing on various aspects of respiratory enzyme systems, each article being written by a member, or by a number of members, of a group of workers engaged in enzyme research at the University of Wisconsin. A historical introduction to the subject by Prof. Elvehjem is followed by chapters on dehydrogenases and oxidases. Then come articles on coenzymes, cytochrome, flavoproteins, etc., an article on the specific and non-specific poisons of respiratory processes and one on hydrogen transport systems. Finally, there are useful chapters on oxidation-reduction potentials, and on the physical-chemical theory of enzyme reactions.

The chapters vary considerably in style and in the thoroughness with which their subject-matter has been treated. Some overlapping has been inevitable. The volume has obviously been compiled with great care, and the reviewer has noticed no misrepresentations of fact or of interpretation. The book should be very helpful to the student and to the worker about to commence research on respiratory enzyme systems. J. H. Q.

THE FAUNA OF THE SEASIDE

The Littoral Fauna of Great Britain
A Handbook for Collectors. By Dr. N. B. Eales.
p. xvii + 302 + 25 plates. (Cambridge: At the
University Press, 1939.) 12*s*. 6*d*. net.

A COUPLE of generations ago, the science of zoology ran a serious risk of being embedded in paraffin. This calamity was happily averted, and the young naturalist hies again to the seahore; but the first line of Dr. N. B. Eales's preface suggests that the poisonous breath of the examiner follows him even there. It may be so; but the fresh air, and the spirit of Edward Forbes and Sir John Graham Dalyell cleanse and sanctify the place, and keep it as sweet as ever. In Edward Forbes's day and for years afterwards, we led the way in the literature of natural history. Forbes and Hanley, Yarrell's "Birds" and Gould's, the early British Museum catalogues, the Ray Society volumes and the Challenger Reports had no rivals. Alas, it is not so now. We might have undertaken the new "Systema Naturæ", but Berlin took the "Tierreich" in hand. There is a "Fauna of the North Sea", but it is written in German; there is an excellent "Faune de France", but none of the British seas.

Dr. Eales has not attempted the task, too big for one pair of hands, of writing a British Fauna, but she has compiled a careful and copious account of the fauna of the sandy beach and the rock-pools; and the shore-fauna is liberally interpreted, for while the sea-mouse must stay outside, the feather-star and the purple heart-urchin, and pinna and the oyster itself are allowed to enter in. Philip Henry Gosse did the same thing more than eighty years ago, and the two little green volumes of his "Manual of the Marine Zoology for the British Isles" were used and loved by many. His plan was different from Dr. Eales's; for he included all the species as best he could but only defined the genera, while Dr. Eales defines the species, but only a selection of these. Gosse's illustrations were the best part of his book; they were only thumb-nail sketches, but they were drawn from life, and every one is unmistakable. The "littoral fauna" defines itself; and yet it took Edward Forbes to show its peculiar character. How in doing so he made good use of Örsted's "De regionibus marinis" and Audouin and Milne-Edwards' "Recherches pour servir à l'histoire naturelle du littoral de la France"; and how very beautifully he himself wrote about it all, and especially about his own so-called "Celtic province", is an old story and a fine chapter in the history of science.

To write like Edward Forbes or to draw like Gosse is no longer given to mortal man. But after the fashion of our own day Dr. Eales has done her work well and handsomely, and many a stude will find precisely what he wants in her book. would cavil over one thing only—the extren correctness, or modernity, of Dr. Eales's nome clature. When Dr. Marion Newbigin wrote h "Life by the Seashore" she apologized for keepi to many old-fashioned and familiar names, witho which such a book as Gosse's "Sea-anemone could no longer be understood. But Dr. Eales w have no half-measures; we must call the on familiar Trochus millegranus *Cantharides clelana* and Saxicava rugosa *Hiatella gallicana*, and so o whether we like it or no.

D. W. T.

MORE ABOUT MICROBES

Microbes by the Million

By Hugh Nicol. (Pelican Special, S28.) Pp. 248 + 8 plates. (Harmondsworth, Middx.: Penguin Books, Ltd., 1939.) 6*d*.

THIS is a wonderful six-pennyworth, and a very interesting and instructive little book. It is written in simple language understandable by ordinary folk, with a considerable sense of humour, and conveys much accurate information on microbes, what they are and what they do.

Commencing with an introduction dealing with the nature of microbes and describing their several kinds—fungi, protozoa, bacteria and algæ—successive chapters deal with the phenomena of their life and the processes associated with their growth and development. In the last hundred pages, chapters are devoted to microbes in the home, in the soil and in the garden, the mechanism of formation of fairy rings, the discharge of its spores by the fungus Sphærobolus, the miracle of the bleeding host, and to a microbe foray on the Norfolk Broads.

Chapters at the middle of the book deal with laboratory technique, and a number of simple experiments are described for the study of microbes in the soil and their influence upon plant and crop life and development, and on the microbiology of disinfectants. All this is set out in interesting fashion, and the reader who has mastered the contents of this little book should have a good idea of the essentials of microbiology and of the importance of microbes for the growth of plants, in the firing of hay-stacks and in the production of silage, and as sources of certain perfumes, drugs, dyes, foods and drinks. A brief but useful chapter is also devoted to stereochemistry—'looking-glass chemistry' as the auth terms it—and Pasteur's work on the tartaric aci is related. No errors of moment have been detecte and the book is adequately illustrated with number of line drawings and six excellent plate

On the pasteurization of milk (pp. 138–140 the author tells but a part of the story, and giv an unfair and inaccurate idea of the objec of the process. Professors do not seem to me with his approval (p. 52), nor do doctors an the medical profession, who are arrogant an ignorant, and—most unkindest cut of all—co cerning milk pasteurization, have "become alli of the merely commercially-minded wholesaler which may seem strange unless one understand medical mentality (p. 139)". A more kindl outlook might have been expected, for so microbiologists owe much to the work of medic bacteriologists.

We gather that the author in writing this boo intended not only to instruct his readers in so and general microbiology, but also desired t extend the 'philosophy' of microbiology to scienc in general, and to impart ideas on the impacts o science upon the social order. In an epilogue, h discusses experimentation and the various meanings given to the term 'experiment', and the valu of statistical analysis of experimental work, bu we think that in his illustrative examples he i less happy than in other parts of the book. Hi remarks on company finance and on the 5½ pe cent *C* stock of the London Passenger Transpor Board, introduced in discussing ratios, also seen out of place and ill-conceived.

With these few criticisms, we leave the book i the hope that it will be widely read and appreciated

R. T. HEWLETT.

PRELIMINARY RESULTS OF THE MARKING OF WHALES BY THE DISCOVERY COMMITTEE

By George W. Rayner

FROM the outset of its investigations, the Discovery Committee has considered whale marking to be a method of considerable importance in approaching many of the problems to be olved in a study of the life-history of whales. It was, however, found difficult to design an efficient mark, and it was not until 1932 that a suitable orm was produced. The mark then adopted consists of a stainless steel tube fired at the whale by means of a 12-bore gun ; it is designed to penetrate the blubber and to remain embedded until the whale is captured and dismembered by the whalers. This form of mark was given a trial during the whaling season of 1932–33 and the results forthcoming during the ensuing year were so encouragng that an extensive programme of whale marking was planned and carried out during 1934–35 and the three following seasons.

In 1934 the Committee's ship, the R.R.S. *William Scoresby*, was commissioned solely for whale marking purposes and spent the whole of the 1934–35 season on the Antarctic whaling rounds lying eastwards of the Greenwich meridian nd extending almost as far as the longitude of Western Australia. At the same time a hired whale atcher operated for about six weeks in the middle f the season from South Georgia, where the area covered was much more restricted. This programme, with the *William Scoresby* working for the whole season on the pelagic grounds to the east and the whale catcher covering a small area round South Georgia in an intensive manner, was repeated during the following two seasons, 1935–36 nd 1936–37. In 1937–38 the programme was modified ; only the *William Scoresby* operated and her work was planned to fill in gaps and to amplify, in the light of results already obtained, that accomplished previously. She commenced earlier in the season to the north of South Georgia and worked eastwards to the Greenwich meridian, then westwards again along the ice edge before the whaling season commenced. She then marked whales across the mouth of the Weddell Sea and made two incursions into the Bellingshausen Sea.

On Chart I is depicted the distribution and ntensity of the marking carried out since 1932–33. There is an area of intensive marking around South Georgia, with a small area around the Shag Rocks, 120 miles westward of the northern point of South Georgia, where very many whales—more than six hundred—have been marked. There are further two extensive areas in which relatively large numbers of whales have been marked, one off Queen Mary Land (85° E.–95° E.), and a second off Enderby Land (15° E.–50° E.). In addition, whales in lesser numbers have been marked over an immense area connecting and extending the regions of more intensive marking ; on the chart the continuous longitudinal lines show where this marking has been relatively dense, the broken lines where it has been scattered. The areas of more intensive marking correspond to some extent with the grounds mostly frequented by the whalers.

The whales supporting the Antarctic whaling industry are, in order of their importance, Blue, Fin and Humpback, the last being relatively unimportant. The majority of the Humpback whales marked have been found off Queen Mary Land. Whales marked around South Georgia have been predominantly Fin, and in the area around the Shag Rocks exclusively so.

Numerically the results are given in the following table :

Species	No. marked	Returns No.	%
Blue	668	33	4·94
Fin	3902	118	3·02
Hump	548	36	6·59
Sei	28	—	—
Right	8	—	—
Sperm	56	—	—
Totals	5210	187	—

In addition to the three commercially important species, it will be seen that an insignificant number of the less important and rarer species have also been marked. The number of marked whales reported as captured is 187, and these have been taken at intervals after marking varying from a few hours to fifteen hundred days.

Since it is not certain how many marks drop out or are missed by the whalers, the percentage figures are not an absolute indication of the percentage of marked whales killed, but they are very instructive as to the relative effect of whaling on

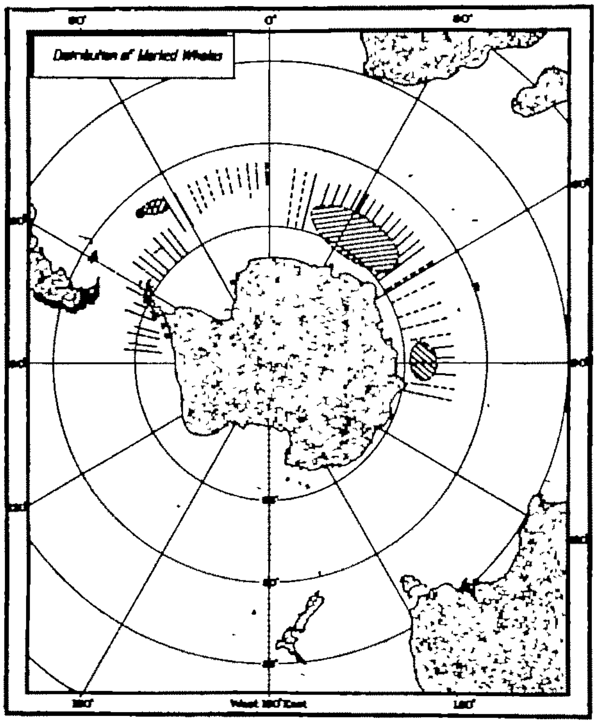

CHART I.

the stocks of the different species. The Blue whale is the species most eagerly sought after by the whalers, although the Fin whale is far commoner. The percentage figures show how the stock of Blue whales is being depleted at a considerably faster rate than that of Fins—5 per cent of the marked Blue whales have been reported killed as opposed to 3 per cent of the marked Fin whales. The percentage of marked Humpbacks taken compared with the figures for the other two species is striking, and it is evident that this whale is being killed off at a surprisingly faster rate than the other two. Soon after whale marking commenced, whaling during the southern winter was resumed off the north-west coast of Australia. This fishery is based on Humpbacks and considerable numbers were taken. Marks recovered showed that these whales were of the same stoc as those marked in Antarctic waters off Quee Mary Land (see Chart II). This stock of whal was, therefore, exposed to a double persecutio which accounts for the comparatively high percen age figure of returned marks. Still more recentl whaling, again exclusively based on Humpback has broken out during the winter season to th south of Madagascar. This double persecution Humpback whales, which their habits rend particularly easy, cannot fail to have a very marke effect on the comparatively small stock, which bearing a burden relatively more than double th of the Fin whale stock and considerably high than that of the Blue stock, already regarded overtaxed.

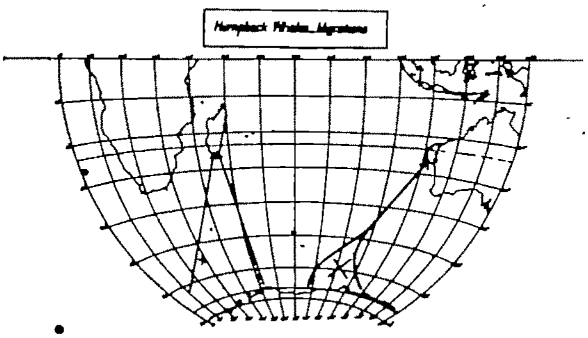

CHART II.

The marks recovered have yielded a gre deal of information on the movements an migrations of the three commercially importa species. Very little indeed had been known pr viously about the wanderings of whales, and wha has been conjectured has rested almost wholly o circumstantial and indirect evidence. The recovere marks demonstrate two main general features whale movement, complementary or contradictor in character as one may care to consider them. O one hand, whales return to the same part the Antarctic season by season on regular track of migration—they may be said to have a stron homing instinct. On the other hand, they tend t spread around the Antarctic from one region t

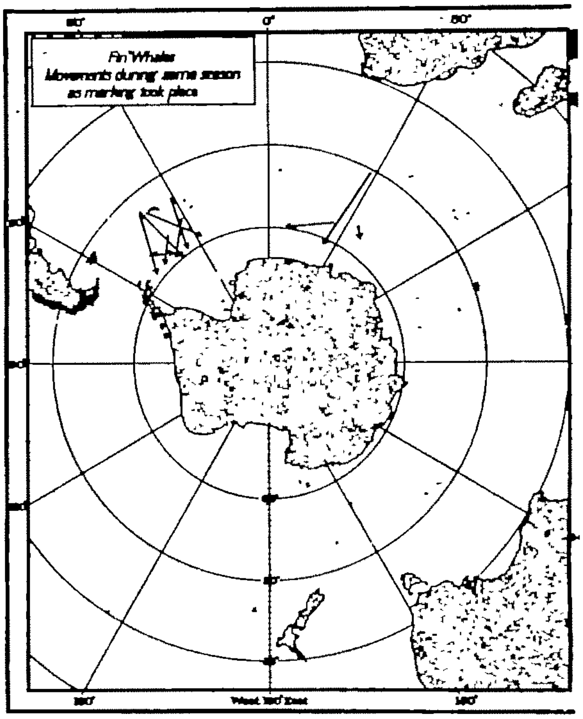

CHART III.

other, a form of movement going on slowly and adually and so far only demonstrable among ues and Fins. One might say that, among the neral body of whales keeping to their regular annels of movement, a few are affected with a anderlust leading them to seek new oceanic stures and fresh companions.

On the accompanying charts the general trends movement and migration are indicated by the rows, the crosses show places where whales have en taken very near the position where they were arked. Possibly more was known about the grations of the Humpback whales than of any er species, and a north and south migration ng the western coast of Australia has been contured for some time past. Marking has confirmed is and has demonstrated almost the full course this migration. Humpback whales marked in Antarctic have been taken in the southern nter off the north-west coast of Australia after ervals up to three and a half years, whilst they ve appeared in the southern summer on the tarctic grounds near Queen Mary Land one, o and three years after marking. One may nfidently say there is an annual north and south gration of Humpback whales along the track own on Chart II. In the western part of the dian Ocean a similar north and south migration idently exists between the Antarctic and the gion of Madagascar. There is shown the return the same area of the Antarctic and the recovery in the tropics during the southern winter. It is most noteworthy that there has been no interchange of Humpbacks between these two regions.

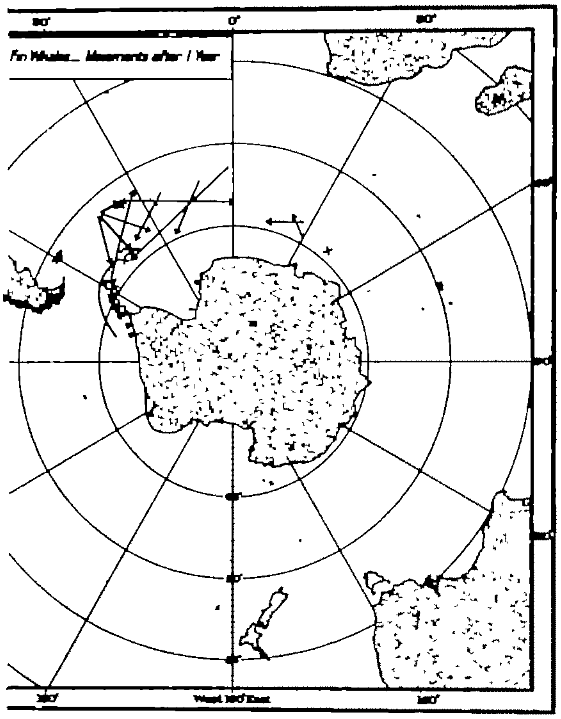

CHART IV.

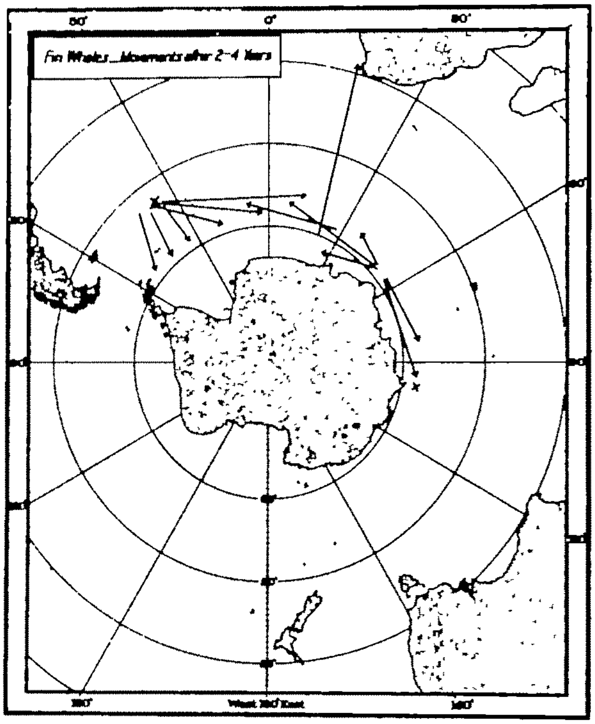

CHART V.

The movements of Fin and Blue whales have been plotted on the accompanying charts according to the time elapsing between marking and capture. Chart III gives the movements of Fin whales during the course of the whaling season, and it shows a general movement southwards towards the edge of the pack ice. A number of Fin whales marked around South Georgia have been taken there during the same season, but never after an interval longer than a few days, so one may consider Fin whales found in these waters to be migrating whales. Further, none of the large numbers of Fin whales marked near the Shag Rocks has been taken the same season by the South Georgia whalers, so there can be little easterly movement here during the season. There is strong evidence that there are regular tracks along which different bodies of Fin whales move on their migrations southward, and it is probable that these tracks may shift a little from season to season.

The movements of Fin whales after a year's time are shown on Chart IV. There has been in many places a return to the same place as marking took place. Further, some arrows show movements which mean essentially a return to the same area both in the east and in the South Georgia – Weddell

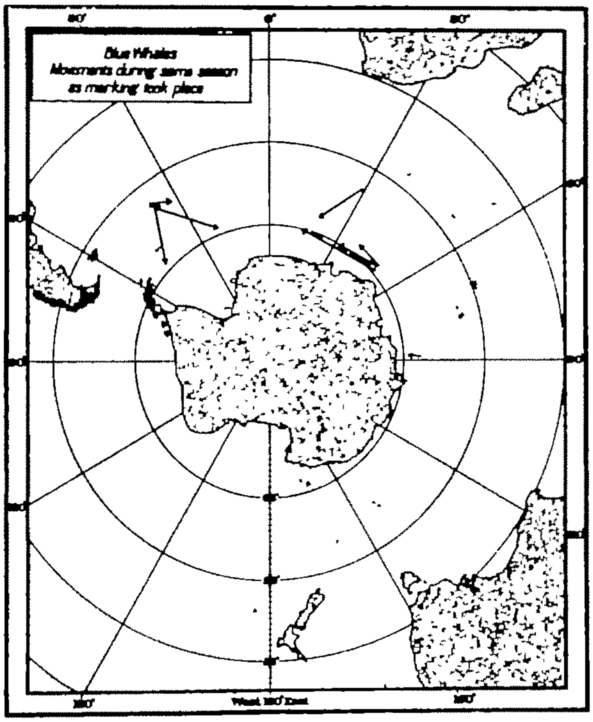

CHART VI.

Sea region. Whales marked around the Shag Rocks have turned up in force near South Georgia and many have been taken to the south again, evidently repeating their movements of the previous year. But wider movements are to be seen, indicating the beginning of spreading. Whales have come into the Scotia Sea area from regions as far apart as the Bellingshausen Sea and the neighbourhood of Bouvet Island, whilst a considerable movement outwards towards the east has taken place.

After longer periods, Chart V, the same description holds good, but the spreading movement is gathering force. There is still a return to the old grounds, but whales have spread outwards from the Enderby Land region eastwards and westwards, and the eastward movement from South Georgia has progressed farther. There are now links connecting more than 180° of longitude, but this movement around the Antarctic may be likened to a relay race in which no individual competitor completes the whole course; in fact, it may be suggested that a complete circumnavigation of the continent may take more than a single generation. The significance of this is that whilst the Fin whales of the Antarctic remain specifically one stock, economically several distinct local stocks may be recognized.

One marked Fin whale has been taken at Saldanha Bay, South Africa, after 2¼ years, and this is the first direct evidence of the migration of Fin whales from the Antarctic towards the tropics. This whale is of particular interest, for wh
marked it was logged as a calf accompanying
mother.

The movements of Blue whales are in ma
respects very similar to those of Fin whales, b
the picture is not so clear. Around South Geor
many marked Blue whales have been taken t
same season as they were marked, but never af
an interval longer than a week, so Blue wha
found here must be on the move and do n
remain long in the vicinity of the island. Th
general movement is southerly and to the west
east (Chart VI). This same general southe
movement is shown on the grounds to the ea
but off Enderby Land there is strong evide
of a definite westward moving stream of B
whales.

After one year, Chart VII, there are returns
the same area as was visited the previous seas
but there is also considerable spreading. Ende
Land whales now show considerable movement
the east which may be considered complement
to their westward movements during the summ
After longer periods of time the spreading mo-
ments shown are actually less than those for
period of about twelve months, but through
the homing instinct is well maintained; it is e
to see that mixing between the different region
going on quite slowly, although it is sufficient
the identical specific characteristics to be retai
throughout the whole population.

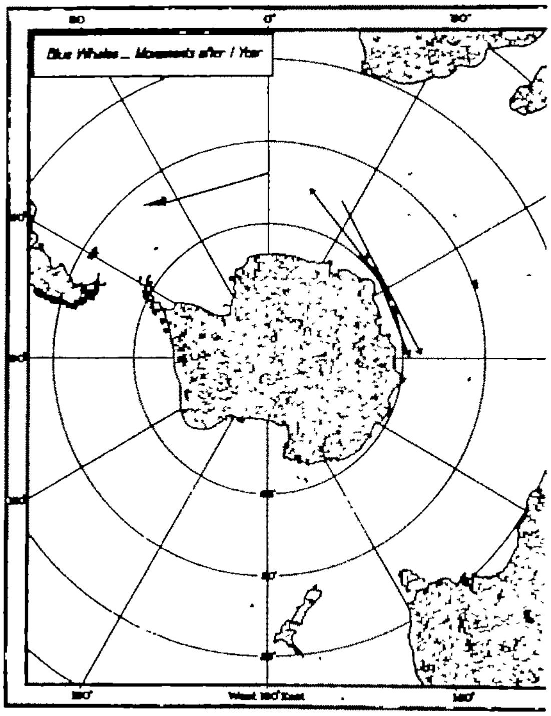

CHART VII.

THE ANTIMONY TREATMENT OF KALA-AZAR

By Sir Leonard Rogers, K.C.S.I., C.I.E., F.R.S.

THE progress during the last quarter of a century, due to many workers, in the treatent of the deadly kala-azar of north-east India d the Mediterranean basin has not attracted the tention it deserves. The epidemic form spread o hundred miles up the Brahmaputra Valley in e last two decades of the nineteenth century, th a case mortality of 96 per cent, and it caused reduction of 31·5 per cent in the population of e Nowgong district in one decade. In 1890 M. Giles incorrectly reported kala-azar to be e to hookworms; in 1897 L. Rogers failed to fferentiate the fever from malaria, but established a house or site infection, which enabled dds-Price to stamp it out of tea estates. The tension of the epidemic to the east was thus ecked for two decades, until the influenza outeak of 1918 caused kala-azar to break out again the Sibsagar district.

In 1903 Leishman and Donovan independently scovered the human stage of the causative otozoal parasite (*Leishmania donovani*), which nald Ross called after them when the flagellate age was discovered by culture by Rogers in 04. Work in the Calcutta Medical College spital also proved that the malarial cachexia of vining (1835) is nothing but a sporadic form of la-azar. The very similar *Leishmania tropica* is e cause of oriental sore, and it was the discovery 1913 by Vianna in Brazil of the effectiveness of rtar emetic intravenously in that infection that l to its successful trial in the Mediterranean in fantile kala-azar in Sicily by Cristina and Caronia ported early in 1915. Rogers immediately ported that he had independently obtained good sults with tartar emetic in the India kala-azar ter trying other antimony preparations, and in tober 1915 both he and Muir published their sults. Further trials showed that both sodiumtimony tartrate, and a colloidal solution of timony sulphide, made by Fisher of the Madras lucational Service, were equally effective and ther less toxic than the potassium salt.

This important discovery came in time to able McCombie Young to control the Sibsagar tbreak through two to three months' intravenous jections of tartar emetic in 80,000 village cases Assam by 1921, with a recovery rate of 88 per nt, against 4 per cent in the early Nowgong idemic. Moreover, the next census showed no ll in the Sibsagar population. Muir also found at systematic treatment of cases in the Kulna hospital led to the disappearance of cases coming from the surrounding villages, and thus kala-azar became an easily controlled disease, given sufficient medical staff, as tartar emetic is very cheap.

It remained for the chemists in India and Europe to seek for even more efficient antimony preparations, and they naturally turned to the less toxic pentavalent ones. The first of these was introduced (and patented) by Dr. U. N. Brahmanchari in Calcutta in 1921, under the name of urea stibamine. This proved less toxic and more effective, and it enabled more than 90 per cent of cases to be cured by intravenous injections within a few days, although so late as 1928, R. N. Chopra, professor of pharmacology in the School of Tropical Medicine, Calcutta, reported this preparation to vary widely in its antimony content and to be uncertain in its composition. In the meantime, von Heyden in Germany prepared a series of pentavalent antimony salts, which were comprehensively tested by L. E. Napier in the hospital of the Calcutta School of Tropical Medicine. Both von Heyden 471, or stibosan, and 693, neostibosan, proved effective, and the latter proved to be the best, with more than 90 per cent of cures after eight daily intravenous injections. In 1937 a final advance was made by the introduction by Kikuth and Schmidt of solulostibosan, which Struthers and Lin in China, and Yates and Napier in Calcutta, found to be equally effective by the much more convenient intramuscular injections, especially in the young children so frequently attacked by kala-azar.

The value of neostibosan is shown by a systematic treatment of all the kala-azar cases in a group of Bengal villages by Napier, with a reduction from 121 and 127 in the first two years, to 12 and 3 in the fifth and sixth years and later to nil. Further, between 1923 and 1933, the Assam Government treated more than 300,000 cases, and relied largely on urea stibamine, which was adopted as the preferable drug in 1935. Between 1925 and 1936 the treated cases in Assam fell to one sixth and the deaths to one ninth of the former rate.

Unfortunately for such a poor country as India, the more rapid effects of the pentavalent preparations over the original trivalent tartar emetic is offset by a curative course of the former costing 160 times as much as the latter, according to Napier, who in 1925 found a course of stibosan to cost £2 5*s*. and one of urea stibamine £3—a prohibitive sum for poor villagers in India. Napier found the village cases near Calcutta to amount to 33 per thousand population, a rate which would give one million in Bengal. The true number must be much less, as in large areas the prevalence is far less than near Calcutta. Owing to their much more scattered distribution in Bengal than in Assam, and the absence of qualified doctors in India villages, the problem of treatment in Bengal more difficult, and requires for its solution a f cheaper preparation, which is equally effective the pentavalent antimony ones. With such a dru and sufficient village medical staff, kala-azar coul be reduced to small proportions.

OBITUARIES

Sir William Prout, K.C.M.G., O.B.E.

THE death of Sir William T. Prout occurred on November 18, at his residence at the Manor House, Lingfield, Surrey. He was born in 1862, the son of Mr. William Prout of Mauritius, and was educated in the University of Edinburgh, graduating in medicine in 1884. He served as a medical officer in Mauritius until his transfer as an assistant Colonial surgeon under the Colonial Office in the Gold Coast in 1888, serving later in the Gambia until his promotion to the post of principal medical officer in Sierra Leone in 1895, where he was an official member of Legislative Council until his retirement in 1906.

During his service in these territories, Prout acquired valuable knowledge and experience in the treatment of tropical diseases, publishing original papers on yaws ("Diseases of Warm Climates" Davidson); *Filaria volvulus* (*Arch. Parasit.*, May 1901); filariasis in Sierra Leone (*Brit. Med. J.*, 1902), etc. He was actively interested in the preventive aspect of tropical medicine, and in the improvement of conditions of life for both Europeans and natives. It was largely due to his initiative that application of the principles of tropical sanitation became increasingly employed in West Africa and elsewhere, with the corresponding improvement in life and health which has been such a marked feature in the early years of this century.

Following his retirement from West Africa in 1906, Prout became honorary lecturer in tropical medicine in the University of Liverpool. He was appointed medical adviser to the Colonial Office in 1912, and later became consulting physician to the Colonial Office until his retirement in 1929, serving during the War of 1914–18 with the R.A.M.C. in Egypt, and being twice mentioned in dispatches. He was one of the original members of the Advisory Medical and Sanitary Committee of the Colonial Office of which he remained a member until his death, and was an ex-president of the Tropical Section of the Royal Society of Medicine, a fellow of the Royal Medical Society, Edinburgh, and a fellow of the Royal Society of Tropical Medicine.

The honour of C.M.G. was conferred on him in 1905, that of knighthood in 1924, and K.C.M.G. in 1928, while he also received an O.B.E. (military) for his war service.

He married Miss Mary Mackenzie in 1888 and had two children, a son being killed during the War of 1914–18.

A. E. HORN.

Mr. P. H. Grimshaw, I.S.O.

PERCY HALL GRIMSHAW found the bent of his li when in 1895 he forsook a clerk's stool in a bank Leeds to fill a post in the Royal Scottish Museum Edinburgh. His earlier interests had been botanic but the chance that, of his colleagues in the Natur History Department, Dr. R. H. Traquair was pa ticularly interested in fossil fishes and Dr. Eag Clarke in birds and mammals, turned his attenti to the lower forms of animal life, and he singled o for investigation the insects and particularly t Diptera. His papers, mostly published in the *Anna of Scottish Natural History* and its successor t *Scottish Naturalist*, which for many years he assist in editing, added greatly to the knowledge of t distribution of insects in Scotland, and he travell widely on the mainland and in the outer islands collect material for his "Diptera Scotica" and oth contributions.

One of his interesting discoveries was the presen in Great Britain of a bot-fly (*Cephenomyia rufibarb* parasitic on red-deer, and his study of the life-histo of the destructive heather-beetle (*Lochmaea suturali* made in connexion with the Committee of Inqui on Grouse Disease, suggested the few measures control which seem to be possible.

When he was appointed keeper of the Natu History Department of the Royal Scottish Muse in 1930, Grimshaw continued the development of t educational appeal of the exhibits, and under supervision was created a Children's Gallery whi for the attractiveness and suggestiveness of collections would be difficult to beat.

On his retiral from the keepership in 1935 he w decorated with the Imperial Service Order. He di suddenly on November 14, at the age of sixty-ni years.

JAMES RITCHIE.

Prof. Anton von Eiselsberg

PROF. ANTON FREIHERR VON EISELSBERG, eminent Vienna surgeon, who died last October, w born at Steinhaus in Upper Austria on July 31, 18 He received his medical education in Vienna, Wu burg, Zurich and Paris, and qualified in Vienna 1884. After serving as assistant to Prof. Billroth, pioneer in visceral surgery, he was appointed succ sively professor of surgery at Utrecht (1893), Köni berg (1896) and Vienna (1901), where he retired 1931. Besides being a first-class operator and markable teacher, he was the author of numerous perimental and clinical publications, of which the ost important were on the occurrence of tetany after erations for goitre (1890), diseases of the thyroid 903), and the modern treatment of fractures 905). He was also co-editor of the *Archiv für inische Chirurgie*, which dedicated to him its 0th volume on the occasion of the twenty-fifth niversary of his professorship in 1926, and of the *itteilungen aus der Grenzgebiete der Medizin und irurgie*. During the War of 1914–18, in which he as appointed consultant to the Austro-Hungarian avy, his services were much in request especially regards abdominal wounds and amputations.

Eiselsberg had many friends in Great Britain, where was elected Hon. F.R.C.S. Edin. in 1905, Hon. R.C.S. England in 1913, where he delivered the nterian Lecture in 1932, and honorary fellow of the yal Society of Medicine in 1928. His autobiography, der the title of "Lebensweg eines Chirurgen", peared a few months before his death.

J. D. Rolleston.

Prof. R. I. Meyer

Prof. Richard I. Meyer, whose death, at the e of seventy-four years, occurred on June 18, was e of the best known inorganic chemists in Germany. rn in Berlin on August 24, 1865, he built up a putation early in life by his researches on rare rths, thallium and scandium; his discovery of andium in tungsten and tin slags enabled him to oduce this element—then considered one of the rest—in sufficient quantity for its thorough chemical d physical investigation. From 1897 onwards, for enty-five years, Meyer was associated with Prof. thur Rosenheim in Berlin in the conduct of a ivate scientific chemical laboratory in which, under e guidance of these two men, university students rried out valuable research work in inorganic emistry—a branch of chemistry frequently neg- ted in the official university laboratories in rmany, which were almost without exception ected by organic chemists.

On his retirement from this laboratory in 1922, of. Meyer was entrusted by the German Chemical ciety with the organization of the eighth edition "Gmelin's Handbook of Inorganic Chemistry" ich, in this new form, is as outstanding in its ld as is the famous "Beilstein" handbook in organic emistry. The achievement of this high standard lue to the comprehensive editorial programme laid wn by Meyer, to his discriminating choice of co- rkers, and to his careful supervision of every detail the publication of the first twenty or so volumes. en after withdrawing from the editorship, he helped writing the manuscript of the introductory volume rare earths; his name, however, was omitted from title page when the volume appeared in print—a e which quite frequently befell 'non-Aryan' authors Germany after 1933.

Not only in his editorial activities were Prof. yer's organizing abilities of high value, but also in work as one of the members of the International Committee on Atomic Weights—for the reports of which he was largely responsible—and as a member of the International Committee on Inorganic Nomenclature. Everybody who came in touch with him was delighted to find not only a chemist of wide erudition and outlook but also a highly cultivated man of great personal charm who was as interested in questions of art, especially music, as in science. It was a matter of intense pleasure and pride to him to see this part of his inheritance come to full development in his highly gifted only son, who became a successful orchestral conductor.

No obituary article on the work of this excellent chemist appeared in any German journal; no official representative of the German Chemical Society attended the funeral of the man who had so devotedly worked for many years in the society's publishing offices. Nevertheless, his name will be gratefully remembered inside and outside Germany as the first editor-in-chief of the new "Gmelin" by present and future generations of chemists who will consult this monumental work.

Prof. F. Y. Loewinson-Lessing

Science, not only in the Soviet Union, but also the world over, has suffered a great loss in the death on October 24 of Prof. F. Y. Loewinson-Lessing, member of the Academy of Sciences of the U.S.S.R. and director of the Petrographical Institute in Moscow.

Franz Youlievich Loewinson-Lessing was born in St. Petersburg on March 9 (February 25, Old Style), 1861. After graduating in 1883 at the University of St. Petersburg, he worked for some years as an assistant at that University. In 1892 he was appointed professor of geology, petrology and mineralogy at the University of Dorpat (Youriev) and in 1902 was the first holder of the chair of geology, petrology and mineralogy in the newly founded St. Petersburg Polytechnic Institute. In 1925 he was elected a member of the Russian Academy of Sciences and director of the Geological Museum. He was the founder and first director of the Petrographical Institute. He was an honorary or foreign member of a number of scientific societies at home and abroad, including the Geological Society of London.

Prof. Loewinson-Lessing was the leading petrologist in Russia and was well known internationally. The bulk of his work was published in Russian, but he also contributed quite a number of papers to English, American, French and German periodicals. Although his main interest was in the petrology of igneous rocks, he published a number of papers dealing with mineralogy, geology and ore-deposits. His books include "Tables for the Determination of Rock-forming Minerals" (English translation, 1893), "Petrographical Tables" (1905, 1911), "Text-book of Crystallography" (1911, 1923), "Introduction to Geology" (1923), "Progress of Petrology in Russia" (1923), "Petrology" (1925), "History of Petrology" (1936, English translation forthcoming). Altogether he was responsible for more than two hundred papers and books.

Prof. Loewinson-Lessing's field work covered almost the whole of the territory of European and Asiatic Russia. He began his work in Karelia and the Caucasus and then extended his activity to the Crimea, the Ural Mountains and Siberia. His petrographical descriptions of the rocks of these regions were used as models by other petrologists. Field description, petrography and petrochemistry of rocks are well blended in all his works. In the domain of theoretical petrology, he is well known for his chemical classification of igneous rocks and his syntectic-liquational hypothesis of magmatic differentiation. In spite of the stress laid by him on liquation as a factor of differentiation, his views on this subject were rather eclectic.

As a teacher, Prof. Loewinson-Lessing was excellent. It is a matter for wonder that he could, in addition to all his research activities and his official duties, contrive to hold numerous classes for students. His lectures were always inspiring and he never lost his freshness of outlook or his mastery of presentation. During a half-century of teaching he trained hundre of geologists and petrologists. He will be affectio ately remembered for his kindness and his help a inspiration by all his colleagues and pupils, amo whom the present writer is proud to inscribe hims

S. I. Tomkeieff.

We regret to announce the following deaths:

Prof. Viggo Christiansen, emeritus professor neurology in the University of Copenhagen, preside of the International Congress of Neurology h last August, on November 3, aged seventy-o years.

Dr. J. F. Lewis, past president of the Ro Photographic Society, on November 28, ag seventy-two years.

Sir Ernest Scott, emeritus professor of history the University of Melbourne, and president in 19 of the Australian and New Zealand Association the Advancement of Science, aged seventy-one yea

NEWS AND VIEWS

Indian Archæology and Indian Problems

Sir Leonard Woolley's Birdwood Memorial Lecture to the Royal Society of Arts, on December 1, was in effect an addendum to his official report to the Government on the organization of archæological studies in India; and it should receive no less careful consideration than the major document when in due course it appears in print. For in the freer atmosphere of the lecture hall, Sir Leonard evidently felt at liberty to allow his trained faculty of scientific imagination to play on the archæological material which had come before him, and to submit the result to his audience in a selection of the problems and possibilities which the study of Indian archæology presents to his mind as calling urgently for investigation—problems no less fascinating in the vistas of the advancement of knowledge they open up than they are evocative of dismay when contemplation turns to the vastness of the field in time and space to be covered. Nor was any short cut offered which might lead by an easy way to the solution of these problems. While Sir Leonard paid due tribute to the work of Lord Curzon in setting up the Archæological Survey of India, and the work which has since been carried out in the triple function of conservation, excavation and publication, he went on to point out with the greatest emphasis that no further advance on sound lines is possible until the essential preliminary groundwork has been completed and a backbone has been built up in a sequence scheme of Indian cultural history. This is the essential task to which effort must first be directed.

It was suggested in Nature of October 28, p. 721, that the inauguration of a new era in India's history might fittingly be marked by the institution on a sound and lasting basis of a scheme of research a study on broad lines of the racial and cultural histo of India. In such a scheme archæological investigati would inevitably take a foremost place. As S Leonard said, "The whole country from north south is strewn with standing monuments of t greatest interest and the greatest beauty and t utmost historical value." He then pointed out th in his analysis of the cultural elements of the ancie monuments of India, certain factors had emerg from which he proceeded to draw conclusions s nificant for the India of to-day. In the architectu of the monuments, he showed, the Mogul strain, wor ing in stone, and the Dravidian, a style derivati from the technique of the worker in wood or ev the jeweller, constituted a clash in styles reflecting political and moral breach between two elemen still represented in the population of to-day. Nev theless, the clash had been resolved in the triump of the Taj Mahal, the Delhi fort, and more especia in Fatehpur Sikri, which showed conclusively th the genius of the two peoples "can combine fruitfu and fertilely". Novel views of the relation of nor and south, thrown out as suggestions presented the results of Sir Leonard's inspection of specifi sites, offer a field of research which, when once t essential groundwork has been completed, mig offer to the Indian peoples a source of unity in pri in their joint cultural achievement in the past.

School of Oriental and African Studies

Notwithstanding the transfer of the School Oriental and African Studies of the University London to Christ's College, Cambridge, the buildi of the School's new premises in the University London area is being pushed forward, and should npleted, if nothing untoward intervenes, by May xt. It was intended that the School should open re for the session 1940–41. In the recently issued nual report for the session 1938–39, the first of rd Harlech's chairmanship of the Governing Body, s recorded that, in response to an appeal which he, Mr. Ormsby-Gore, when Secretary of State for Colonies, had put forward, the Colonial Office s promised a sum of £4,380 per annum in subntion of the work of the School, while a grant of ,500 has been made by the University Court for remainder of the quinquennium for the establishnt of five posts—one lectureship in Japanese, one Turkish, and three in Arabic dialects, while a later nt of £500 for a period of not less than three years s made for a lecturership in Sinhalese. The number students, though representing a slight decrease, s still more than four hundred. While the mbers from Great Britain and the Empire owed a decrease, there was a considerable dition to those from Germany and the United ates.

In the course of the report, reference is made the valuable assistance towards African studies ven by grants from the Rockefeller Foundation ich during the last seven years have amounted in ms allocated to public bodies and to individuals a total of £18,000. It will be remembered that was through the assistance of a grant from this urce, spread over five years, that the International stitute of African Languages and Cultures was abled to plan and carry out its valuable scheme of ganized African research in the field, of which the nefit is now becoming apparent not only in the onographs in course of publication but also in e projects for further research which directly or directly have sprung from that scheme.

r. Jean Paul Marat

In a recent paper (*Hippocrate*, 7, 379; 1939) Dr. enri Candiani protests against the unjust and cruel eatment which Marat has received not only from urrilous pamphleteers but also from reputable storians such as Michelet, Taine and Carlyle. While t attempting to refute all the legends and calumnies ncerning the "Friend of the People", Dr. Candiani nfines himself to the scientific and medical aspects his hero. So far from being a charlatan or merely a rse-leech, as Carlyle called him, he was a properly ualified medical man of St. Andrews who, during s residence in London, had a good practice in Soho hen that district was a fashionable quarter. His Essay on Man" (1775), more than half of which is voted to anatomy, is a philosophical and psycho-gical work, in which he has been recognized as the ecursor of Cabanis, Broussais and Gall. In his Essay on Gleets", published the same year, he iticized certain errors of treatment current at the me, including the use of hard and irritating bougies, r which he substituted softer instruments. In 1776 made an important contribution to ophthalmology his "Enquiry into a Singular Disease of the Eyes", in which, as Prof. Truc of Montpellier has shown, he gave a description of astigmatism which preceded the classical account of Thomas Young by more than twenty years. But it was as a pioneer in electrotherapy, on which he wrote in 1782 and 1783, that Marat chiefly deserves mention in the history of medicine. According to Dr. W. G. Turrell of Oxford, his work on this subject was on far more scientific lines than the writings of any of his predecessors or even than the publications of many of his successors. In conclusion, Dr. Candiani describes Marat as a conscientious experimenter, resolutely hostile to absurd theories or hasty generalizations.

Food of Game Ducks

VARIOUS causes have contributed to reduce, to a serious extent in some cases, the numbers of game ducks in the United States and Canada, and the interest of the public and the self-interest of the multitude of shooters alike demand that measures should be taken for the encouragement and multiplication of the duck population. The U.S. Department of Agriculture has responded to the demand by the publication of a pamphlet (Washington, D.C.: *Tech. Bull.* No. 634; 1939) of 156 pages and 153 plates, with the aim of spreading dependable information on which programmes for the improvement of breeding and feeding grounds may be based. To minimize waste of funds and loss of effort through the introduction of unsuitable foods, it is essential that the important plant and animal foods of the various species be known and that consideration be given to the range of particular species and environmental and other limiting factors. By making use of data accumulated through many years by the Biological Survey, the authors, A. C. Martin and F. M. Uhler, have presented a thorough-going treatise which from three aspects gives a lead to duck conservation and propagation. The first section presents a census of foods, based upon analyses of nearly 8,000 stomachs or gullets of eighteen species of game ducks, and indicates the regions in the United States where each food is preferred. The second part, by means of photographs and concise descriptions, is designed to facilitate recognition of these foods; and the third part contains practical suggestions on the propagation of the food of waterfowl and the development of feeding grounds.

Fauna of the Marquesas Islands

ISOLATED in the central Pacific Ocean, farther from the continents than any others, with one exception, themselves the relics of volcanoes perhaps of Pliocene age, the Marquesas Islands afford a perfect setting for the study of an oceanic island fauna. The study has been carried out with thoroughness by A. M. Adamson, who spent fifteen months collecting on the Islands and has made a survey of the literature bearing on the problem (*Bull. Bernice P. Bishop Museum, Honolulu*, 159, 93; 1939). Marquesan animals are related to those of the island groups lying to the west and south-west, Samoa, Society, Cook, etc., but they show little affinity to the fauna of Hawaii. The faunal drift has been ultimately from the Indo-Malayan region, with a sprinkling of Australian forms, but whether the Islands were populated by oceanic dispersal or by way of hypothetical land bridges seems difficult to decide, and the author gives the arguments for and against both possibilities. Whatever the origin of the fauna, it dates from not later than early Tertiary times, and as might be expected isolation has resulted in the development of a high proportion of species distinctive of the Islands, although between the isolated islands of the group, variations are pronounced only in certain families. Naturally the fauna contains a varied assortment of species, particularly mammals and birds, introduced by man, some, such as the so-called 'native' rats and pigs, probably by the early Polynesian voyagers, and all the other mammals, with the doubtful exception of dogs and mice on some of the Islands, by white adventurers.

European Rural Life

A PUBLICATION of much interest has been produced by the International Institute of Agriculture in Rome. It is entitled "Documentation for the European Conference on Rural Life, 1939", but in spite of its title it contains much of real value and much that has not previously been collected into one volume. Especially valuable is the long chapter on land reclamation and improvement in the different countries of Europe, including statistical information. This leads to a chapter on the improvement of crops, stocks and rural industries, where again various State efforts are discussed. In addition, there are useful summaries of land tenure systems in Europe and a full discussion of the present and potential density of agricultural populations as well as discussion on the economics of farming in different countries. The publication runs to nearly four hundred pages, and has various references to other sources of information.

Music in Mental Diseases

DR. ARTHUR H. HARRINGTON, late superintendent of the State Hospital for Mental Diseases, Howard, Rhode Island, states that in some public institutions in the United States the value of music systematically applied with a therapeutic purpose has been recognized as an aid in institutional activities (*Mental Hygiene*, **23**, 601 ; 1939). He has found that though technical instruction for groups of patients has only a very limited value, and does not produce sufficient return for the time and effort expended, mass and group singing of properly selected compositions under proper direction with the psychological aim always in mind, has a definite therapeutic value. Instrumental music of a subdued type seems to have a desirable psychological effect at meal-times, when it produces quiet and repose. In Dr. Harrington's experience the physical act of singing increases a number of bodily functions, stimulates respiration and heart action, gives increased oxygenation to the tissues and often has a favourable effect upon morbid mental states.

Memorandum on Influenza

THE Ministry of Health has issued a revis edition of the Memorandum on Influenza, fi published in 1919 and revised in 1927 (Memo. H. Stationery Office. 2*d*. net). It is pointed out th since the great and fatal pandemic in 1918–1 influenza epidemics in England and Wales ha shown a decided preference for the first quarter the year. The disease is caused by a filterable vir and the incubation period is about 48 hours. Infecti is conveyed from the sick to the healthy by t secretions of the respiratory surfaces. Beyo adequate ventilation, with perhaps gargling with antiseptic solution after close contact with infectio little can be done for personal protection. At t first feeling of illness, the patient should go to b in a room by himself, keep warm, and seek medic treatment.

Health Problems of Industry

THE investigations carried out under the directi of the Industrial Health Research Board, Medic Research Council, during the year ended June 19 are contained in the nineteenth annual report of t Board, recently issued (H.M. Stationery Office. 6 net). These include a research on the toxicity of va ous volatile organic substances, now increasingly us as solvents in industry, work on mental integrati with special reference to accidents and vocation fitness, and on vocational aptitudes, and research on the physiological problems of heating and ventil tion. Environmental conditions, such as lighting a vision, noise and deafness, and the effects on heal produced by inhalation of dusts met with in industr have also been investigated, and summaries of t results obtained are included in the report.

National Research Council of Japan

A RECENTLY received report of the Nation Research Council of Japan (**2**, No. 8) covers t period April 1938–March 1939. In addition to pa ticulars of the serial publications issued, the repo includes summarized accounts of the annual gener meeting and of the various divisional and committ meetings, with notes on the thirteenth conference the International Union of Chemistry and the Tent International Congress of Pure and Applied Chemist and other international meetings at which the Counc was represented. Besides details of the officer members and committees of the Council, the repo includes a long obituary notice of Baron J. Sakur by Dr. N. Matsui (see also NATURE, Aug. 5, 193 p. 234), reviewing not only his scientific work b also his work in promoting research activity Japan and her international cultural relations. Appe dixes list serial publications received from abroa and tabulate those of the Council already issue

Phytopherol: a Standardized Solution of Vitamin

VITAMIN E is now being manufactured in Gre Britain on a commercial scale and has been p within the reach of all by the British Drug House who issue it as capsules of an oily solution containi mgm. *dl*-α-tocopherol per 5 minims. The booklet ued by this firm contains a brief survey of the emistry, physiological function, and general clinical plications of vitamin E. It is pointed out that not ly may vitamin E be effective in combating sterility the female in cases of habitual or threatened abor-n, but also that types of pregnancy toxæmia and emature separation of the placenta as well as menorrhoea and vulvovaginitis may also respond vourably to administration. It may be effective male impotence and may produce descent of topic testes. About three pages of the booklet s devoted to a description of work on the relation-ip of vitamin E and the anterior pituitary, carried t in the B.D.H. Laboratories by Barrie.

rthquake near Seattle

THE United States Coast and Geodetic Survey, in -operation with Science Service and the Jesuit ismological Association, states that an earthquake as experienced in the State of Washington, U.S.A., November 13, 1939, at approximately 7h. 45m. 49s. C.T. Reports of the earthquake were received from e seismographic stations at Georgetown, Chicago, rdham, Pasadena, Pittsburgh, Tucson, St. Louis, tte, Weston, Williamstown, Sitka, College, Phila-lphia and Lincoln. From these reports, the epicentre s been calculated to have been near lat. 47° 35′ N., ng. 123° 15′ W., which is to the west of Bremerton d south-east of Mount Olympus. No damage has en reported. It is well known that the western le of the American continent is more liable to rthquake shocks than the eastern side, though both regards frequency and intensity the State of lifornia appears to have suffered more in the past an the State of Washington or any other of the ighbouring States.

he Colonial Service: Appointments and Promotions

THE following appointments and promotions in the lonial Service have recently been announced: . G. Cowley, agricultural officer, Kenya; C. J. awkins, agricultural officer, Nyasaland; M. A. G. anschell, agricultural superintendent, British uiana; J. Paine, agricultural superintendent, Gold ast; T. A. Phillips, agricultural officer, Nigeria; . W. T. Webb, agricultural officer, Nyasaland; . S. T. Bowden, veterinary officer, Malaya; R. A. amilton, assistant meteorologist, Nigeria; J. A. eid, research student, Institute of Medical Research, ederated Malay States; D. L. Blunt, director of griculture, Nyasaland, to be director of agriculture, enya; C. J. McGregor, agricultural officer, to be nior agricultural officer, Tanganyika Territory.

he Parliamentary and Scientific Committee

THE Parliamentary Science Committee has now en re-formed on a new basis and will henceforward e known as the Parliamentary and Scientific Com-ittee. Following a meeting on November 8, it was greed to form an emergency committee forthwith d to invite all former officers and members of the ecutive committee to serve on it. A meeting of this emergency committee was held at the House of Commons on Wednesday, December 6. Following the resignation of Mr. S. F. Markham as chairman in view of his forthcoming service abroad, Captain L. F. Plugge, M.P., was elected to the chairmanship. Prof. B. W. Holman and Mr. Alan E. L. Chorlton, M.P., will remain as vice-chairman and deputy-chairman respectively, while the new secretary is Mr. Christopher Powell. It was reported at the meeting that promises of support had been received from a large number of the organizations which previously supported the Parliamentary Science Committee.

Courses in Technical Optics

COURSES in technical optics, adapted for students with an initial training in physics or mathematics, are now being given as usual at the Imperial College of Science and Technology, South Kensington. The Technical Optics Section was founded in 1917 to meet the demands of the optical instrument industry and the Services for assistants with an optical training; and although a good many students have taken the course since that time, the present demand exceeds the supply. There are vacancies for a few more students who are prepared to begin work at once. The work is of a varied character, embracing many aspects of optical knowledge in its application to industry and to other sciences, and is of great national importance.

Cecil Peace Prize

A CECIL PEACE PRIZE of £100 is offered yearly for an essay on some subject connected with the maintenance of international peace, and having some bearing on the principles or work of the League of Nations. It is open to all undergraduates, without distinction of sex or nationality, of any university or university college in Great Britain or Northern Ireland, who have not attained the age of twenty-five years on the last day for submitting essays. The subject for the year 1940 is "What were the reasons for the 'failure' of the League of Nations in the years following 1930; and what steps should be taken after the present war to strengthen international authority?" The essay must be sent to the Secretary, Universities Bureau of the British Empire, 88A, Gower Street, London, W.C.1, so as to arrive on or before November 1, 1940. Further information can be obtained from the Secretary.

Institution of Electrical Engineers

THE meetings of the Institution of Electrical Engineers will be resumed in London during the second half of the current session if the present conditions continue. This applies to the ordinary meetings, informal meetings, meetings of the three technical sections and of the London Students' Section. As regards activities in the provinces, the various committees will decide in the light of local conditions whether they are able to carry out programmes of meetings, visits and functions. The first ordinary meeting of the programme for the second half of the session will take place on January 25, at 6 p.m., when a discussion on "Fire-Fighting Equipment for Electrical Installations", based on the E.R.A. Report on this subject, will be introduced by Messrs. H. W. Swann, J. Hacking and R. A. McMahon.

Announcements

SIR ARTHUR SMITH WOODWARD, lately keeper of the Department of Geology, British Museum (Natural History), has been awarded the Hayden Memorial Geological Medal of the Academy of Natural Sciences, Philadelphia. This Medal, which is awarded every three years, has been given in recognition of Sir Arthur's notable contributions in the field of vertebrate and invertebrate palæontology. The Hayden award was founded at the Academy in 1888 as a memorial to Ferdinand Hayden, a member of the Academy's staff and director of the United States Geological Survey; former recipients of the award include Edward Drinker Cope, Thomas H. Huxley, William Berryman Scott and Andrew C. Lawson.

SIR GEORGE STAPLEDON, professor of agricultural botany in the University College of Wales, Aberystwyth, and director of the Welsh Plant Breeding Station, has been presented with the Gold Medal and certificate of honorary membership of the Royal Agricultural Society of England for distinguished services to agriculture.

THE Minister of Agriculture and Fisheries has appointed two additional members to the war-time Poultry Advisory Committee recently set up to give advice on matters affecting the interests of the poultry industry under war-time conditions. They are Captain Guy Clifford, a Lancashire poultry farmer, who is vice-president of the National Poultry Council and chairman of the Lancashire Utility Poultry Society, and Prof. T. J. Dalling, professor of animal pathology in the University of Cambridge.

MR. G. ANDREW, formerly lecturer in the Geological Department of the Fuad el Awal University, Cairo, has been appointed Government geologist in the Anglo-Egyptian Sudan.

MR. G. O. JONES has been appointed research fellow in the Department of Glass Technology in the University of Sheffield.

FOR many years it has been the practice of Emmanuel College, Cambridge, to invite suitably qualified candidates to make application for a research studentship to which the College elects in July. For the time being the governing body feels it is unable to make such an award. In certain circumstances, however, it is prepared to supplement awards of other bodies to research students who are making application, even if provisional, for admission to Emmanuel College. Applications must reach the Master, Emmanuel College, not later than June 30 in any year.

ACCORDING to a report from a corresponde which is printed in *The Times* of December 12, t Institute of Experimental Physics of the Univers of Warsaw has been totally demolished. The wh installation of the Institute has been dismantled a all the instruments for scientific research have b sent into the Reich.

A LIBRARY devoted to the history of medicine l been established at the Yale University School Medicine. Its basis will be formed by the collectic of the late Dr. Harvey Cushing and of Dr. John Fulton, who is Stirling professor of physiology in t Yale Faculty.

ON October 17, Dr. Thomas Parren, surgec general of the United States Public Health Servi received the Sedgwick Medal of the American Pub Health Association for distinguished service in pub health, the presentation being made by Dr. Willia Rosenau, a former medallist.

EPILEPSY has been made a notifiable disease California since September 19.

THE sixth Australasian Medical Congress (Briti Medical Association), which was to have been he in Perth next September, has been postpon indefinitely.

THE issue of the *Nederlandsch Tijdschrift Vc Geneeskunde* of November 4 contains an account the proceedings of the autumn meeting of the Dut Society of the History of Medicine, Mathematics a Natural Science held at Leyden on October 22.

THE October issue of the *Bulletin de l'Office Int national d'Hygiène Publique* contains the statisti for Palestine of the population, birth-rate, gene and infant mortality, and the incidence of infectio diseases according to religious groups from 19 until 1937.

A CLASSIFIED index of entomological contributio to the *Scottish Naturalist*, from 1871 until the end 1938, appeared in that journal from July un November 1939. It covers a large proportion of t records of Scottish insects during the period question and has now been issued in complete fon consisting of sixty-six pages and cover. Copies, pri 2*s*., may be had from Messrs. Oliver and Boyd, Lt Tweeddale Court, 14 High Street, Edinburgh, 1.

THE variations in the number of marriages a births in Germany within recent years are shown l the following official figures: In 1932 the marriag numbered 517,000, in 1933 639,000, and in 19 720,000. In 1935 there was a fall to 651,000 and 1936 to 610,000, followed by a rise to 620,000 in 193 There has also been a recent increase in the numb of births. In 1933 they numbered 971,000, in 19 1,119,000, in 1935 1,164,000. in 1936 1,179,000, a in 1937 1,275,000.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1016. CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

-Ray Measurements on Wet Insulin Crystals

THE importance of water f crystallization in maintaining the regular strucure of protein crystals has lready been shown in the -ray examination of wet nd dry crystals of three ifferent proteins: lactolobulin, hæmoglobin and hymotrypsin[1]. It is now ossible to add insulin to his list. Although the riginal photographs[2] of ir-dried insulin crystals recorded no X-ray reflections ith spacings smaller than A., those of the wet rystals examined in their mother-liquor show reflecions with spacings of 2·4 A. r less, which indicate that ere there is regularity in he structure down to tomic dimensions.

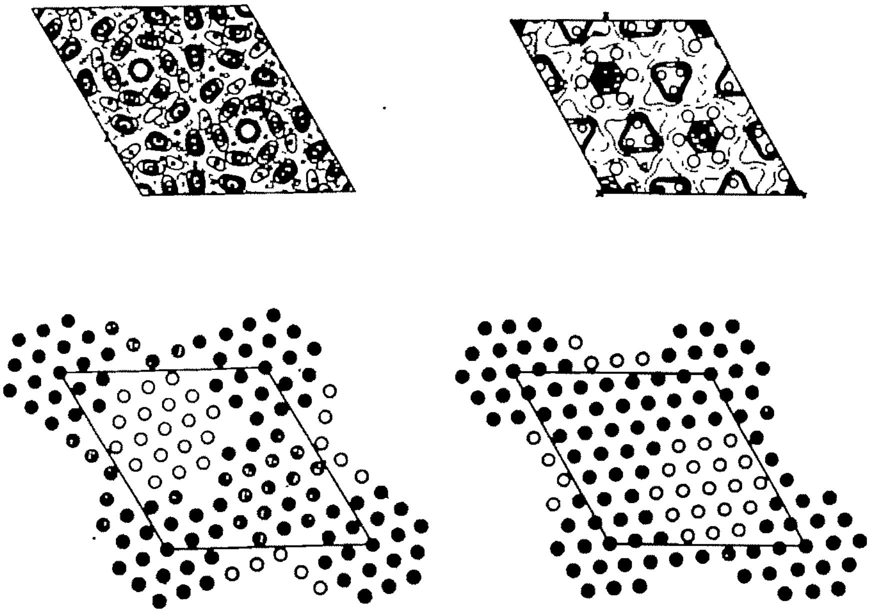

Fig. 2.

ABOVE: PATTERSON PROJECTIONS ON THE BASAL PLANE OF THE STRUCTURE OF (LEFT) WET AND (RIGHT) DRY INSULIN.

BELOW: ARRANGEMENT OF HEXAGONAL ARRAYS OF POINTS, (LEFT) EXPANDED (CF. WET INSULIN) AND (RIGHT) CLOSE-PACKED (CF. DRY INSULIN).

The new measurements ave been made on three ifferent samples of insulin rystals. The first of these vas given to us by Dr. . N. Macbeth (Organon aboratories), and consisted of crystals in their mother-liquor. The others were recrystallized by us t two different pH values, approximately 5·2 and 6·2 respectively. In these cases the mother-liquor was essentially a mixed sodium potassium phosphate buffer prepared as previously described[2]. All the crystals were similar in appearance to those obtained earlier. Their density, measured by flotation in a sodium dihydrogen phosphate solution pH 4·5 and in a sodium citrate buffer solution pH 5·7, varied between 1·276 and 1·283, lower than the values up to 1·315 found for the dry crystals. In an attempt to check the molecular weight calculation, preliminary X-ray measurements have been made on crystals immersed in both these density solutions and in dilute $M/15$ sodium dihydrogen phosphate solution.

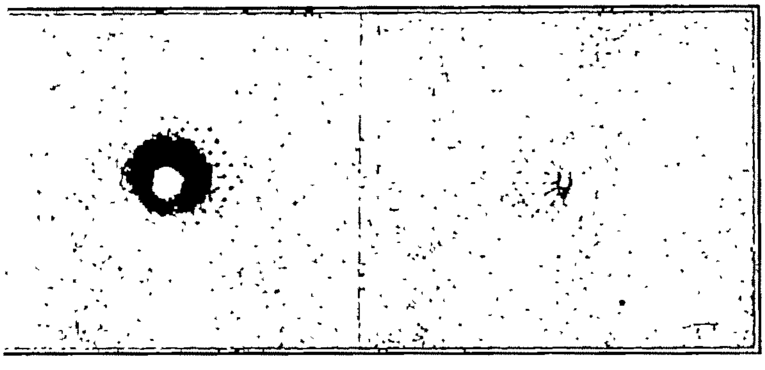

Fig. 1.

X-RAY PHOTOGRAPHS OF ZINC INSULIN SHOWING (*hk0*) REFLECTIONS. LEFT: WET CRYSTAL IN MOTHER-LIQUOR; RIGHT: ORIGINAL AIR-DRIED CRYSTAL. (SCALE NOT IDENTICAL.)

The crystal lattice of the wet insulin crystals photographed in their mother-liquor proves to be a moderately expanded form of that found for the dry crystals. The unit-cell dimensions for the hexagonal unit-cell (correct to 0·5 per cent) are: $a = 83\cdot0$ A., $c = 34\cdot0$ A., as against $a = 74\cdot8$ A., $c = 30\cdot9$ A., for the air-dried crystals, or for the rhombohedral true unit-cell, $a = 49\cdot4$ A., $\alpha = 114°\ 16'$, wet, and $a = 44\cdot4$ A., $\alpha = 114°\ 28'$, dry. Using the mean density 1·28 found above, and assuming that the molecular weight of the insulin present is 37,600 as measured on the dry crystals, it is possible to calculate the wet-cell molecular weight as 52,400, and the weight of the liquid of crystallization present as 14,800—28 per cent of the total.

How much meaning this calculation has is doubtful in view of the increasing evidence that the protein crystal lattice itself is penetrated by ions and molecules from the various immersion media. To a first approximation, the crystal structure proves to be unaltered by immersion in the citrate density solution or in the dilute phosphate solution *p*H 4·5. But X-ray photographs of crystals immersed in the phosphate density solution show both a small shrinkage of the crystal lattice, of the order of 3 per cent, and an absence of X-ray reflections with spacings less than 7 A., as in the case of the air-dried crystals. Whether this alteration is due alone to the concentration of ions in the immersion medium, or to this factor combined with the low *p*H, it is clear that here there has been a withdrawal of water from the crystal which has produced a disorganization of the structure comparable with the effect of drying.

These changes are accompanied by changes in the intensities of the X-ray reflections which should provide the means for their fuller interpretation. As is shown in Fig. 1, the X-ray intensities from the wet insulin crystals differ strikingly from those given by the dry crystals. A preliminary Patterson projection on the basal plane (0001) indicates that the differences are to be correlated mainly with a change in the relative orientation of the molecules as a whole (Fig. 2). The main interatomic distances about the origin are similar to those observed for dry insulin but are shifted through a small angle relative to the original pattern. It seems relevant to the general problem of protein structure that the new Patterson peak positions also approximate closely to one of the systems of close-packing of hexagonal aggregates postulated by Bernal[3] to account for the original peak positions. The new system is derived from that of Bernal by sliding the molecular groups relative to one another, leaving spaces to be occupied by water at definite positions in the lattice in the neighbourhood of 0, $\frac{1}{3}$; 0, $\frac{2}{3}$, etc. In agreement with this, the X-ray reflection $33\bar{6}0$ is much the most sensitive to changes in the crystal immersion medium. It is present for the dry crystals, absent for crystals photographed in their mother-liquor, and again present for crystals in the phosphate density solution, although the intensities of most other comparable X-ray reflections are here unchanged compared with the wet crystals. Such controllable variations in the X-ray intensities given by a protein crystal ha been sought for some time, and here, in insulin, ought now to be able to follow further chang produced both by alterations in the immersi medium and by replacement of the bound zinc cadmium or nickel.

DOROTHY CROWFOOT
DENNIS RILEY.

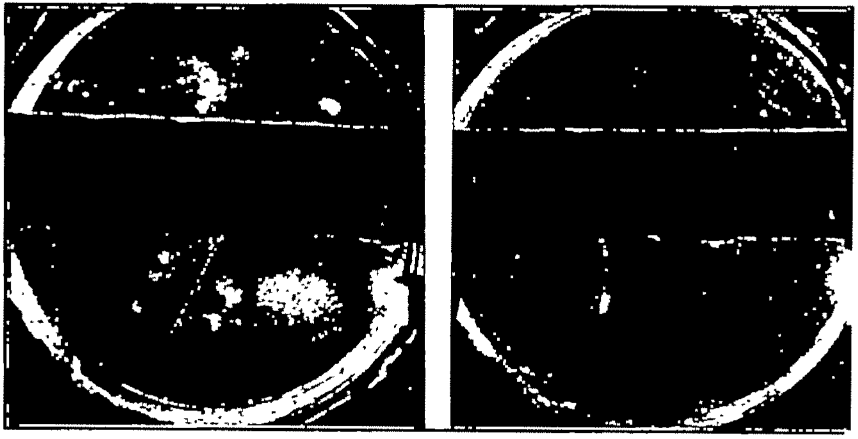
Evidence for the Occurrence of Meson Pairs

WE have taken a number of photographs with counter-controlled cloud chamber in a tunnel 30 under London clay. (1) 630 photographs were tak with a 1·4 cm. lead plate inside the chamber; (948 photographs were taken with a 2·5 cm. le plate inside the chamber; (3) 780 photographs we taken with a 2·5 cm. lead plate inside the chamb and 15 cm. of lead above the chamber.



a *b*

80 per cent of all the photographs show one sing ray penetrating the lead plate without appreciab deviation. We consider that most of these must mesons. 125 of the photographs show evidence electronic showers.

In five photographs, two apparently associate particles go through the lead plate without pe ceptible change in direction and without producir secondaries. Three of these photographs we obtained with arrangement (1), one with (2), an one with (3). In the accompanying reproduction, was obtained with arrangement (3), the ang between the tracks is 1·5° and they seem to diverg from a point 3 m. above the chamber. They hav therefore, both penetrated the 15 cm. of lead abov the chamber.

A possible explanation of these photographs that they show meson pairs.

Alternative explanations which must be considere are: (*a*) the random coincidence of independer mesons; (*b*) one or both of the particles are electron and happen not to produce secondaries; (*c*) one both of the particles is a proton.

It is estimated that two tracks which appear ntical must be formed within 1/50 sec. of one other. The chamber is set off by the counters, on average, once in 12 minutes, so that the probility of the random simultaneous appearance of o non-associated rays is of the order 3×10^{-5}.

An electron capable of passing through 2·5 cm. lead without sensible deviation by ordinary attering must have an initial energy greater than ^{9} e.v. The probability that only a single electron high energy would emerge from the 2·5 cm. plate ay be calculated from cascade theory as 0·007 for 10^9 e.v. particle and negligibly small for one of gher energy. The particles which penetrated cm. of lead could not be electronic.

J. G. Wilson[1] has calculated that the probability a meson producing a knock-on proton of high ergy is much too small to account for our photoaphs, and any process by which one proton knocks another would be expected to give rise to a umber of slow protons distinguishable as heavy acks. No such tracks have been observed.

We consider that our photographs are best regarded evidence for meson pairs.

Occurrence of Greenockite in the Mendips

Although small amounts of greenockite (cadmium lphide) have been found in Scotland associated ith zinc blende, the mineral has rarely been found England. In July last one of us (A. W. G. K.) was amining blende from a small dump at some old orkings at a hamlet called Green Ore near Chewton endip. The area was at one time worked for lamine (zinc carbonate) and most of the material the dump consisted of this; but blende, galena and rytes were also present.

Thin layers of a yellow mineral, ranging up to out 1 mm. in thickness, were noticed in various all patches in the blende. These were afterwards amined spectroscopically and chemically and oved to be greenockite. There appears to be no cord of the mineral having been observed in the endips before this.

A New British Locality for Fluorite in Somerset

Although small amounts of fluorite were recorded any years ago from the Avonian Limestone of the von Gorge at Clifton, it does not appear to have en found there again, or to have been previously corded from any part of the Carboniferous of the joining Mendip Hills.

In November last year, I found minute traces of a rk purple granular mineral in a disused quarry Shipham Gorge, near Axbridge on the south side the Mendips. Subsequent tests showed this to be orite, but the amount was too small for satisfactory amination.

This year, however, further search has resulted in the collection of a number of small but well-formed crystals. These crystals range in colour from colourless to almost black, purple and mauve shades being the only ones so far noticed: they are all small, the largest being about 3 mm. across the cube face. The simple cube, $a\ \{100\}$, and the low 4-faced cube, $f\ \{310\}$, are the most frequent forms, but combinations of these two also occur. Some crystals recently found are very complex; many crystals are well zoned and in some specimens the fluorite crystals are accompanied by beautiful little bright crystals of chalcopyrite and little velvety black hemispheres of hæmatite.

The fluorite appears to be confined more or less to one band in the quarry and occurs in granular calcite filling vesicles in the black limestone of the *C*-zone. These vesicles are numerous, but the majority appear to contain no trace of fluorite.

Careful search in this and other parts of the Mendips over a number of years has failed to produce any other specimens, and so far this appears to be the only locality in the district.

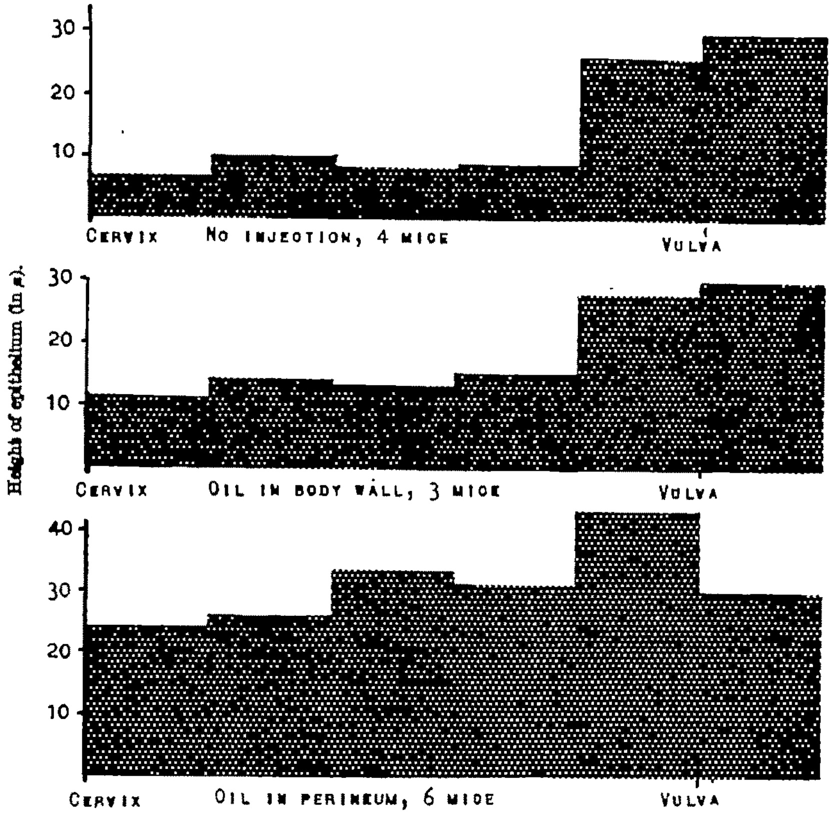
Œstrogen Depot Formation

In a recent communication, Zondek and Sulman[1] showed that, unlike œstrone, the hormone esters and stilbœstrol in oil, when injected into the rat, remain at the site of injection for a considerable time and from there are slowly absorbed.

Some time ago I undertook an investigation into the local effect upon the vaginal epithelium of the ovariectomized mouse of small doses of œstrone in arachis oil. The preliminary results showed little of interest, and the inquiry was put aside under pressure of other work. At the time I noticed, however, that a few control mice which received small doses of arachis oil alone, and showed little or no effect when the dose was injected into the body wall, did show proliferation of the vaginal epithelium, resembling that preceding œstrus, when the dose was injected into the perineum. The results are shown in the accompanying diagram. With doses of oil of from 0·0025 c.c. to 0·005 c.c. after times between 24 and 48 hours, the height of the epithelium is increased. This increase is a good deal more noticeable when the dose is administered in the perineum than when it is injected into the body wall.

From this it appears that (1) arachis oil, or some part of it, has the property of initiating some proliferation of the epithelium lining the vagina of the ovariectomized mouse; (2) this effect is rather localized.

The localization of the effect of the oil may in all probability be taken to indicate that the oil, or some fraction of it, forms a depot at the site of injection and is not distributed immediately all over the body. If this is so, then it may be that the depot-forming qualities of the solvent have some bearing upon the depot-forming qualities of the œstrogenic injection as a whole. The depot-forming qualities of arachis oil appear to have been made plain in these experiments through the accident of its effect upon this epithelium, which can be measured. It may be that some œstrogens, for example the esters mentioned and also stilbœstrol, simply tend to remain dissolved



The height of the epithalium was measured first at the cervix and then once on each side of a longitudinal vertical section every 100 μ until the vulva was reached. The two measurements, one on each side of the section, were then averaged. The length of the vagina was then divided into five equal parts. The average was then found of those previously found averages which fell within each of these five segments. The resulting quantities are the ordinates in the histogram. The first five 'cells', counting from the left, represent the five equal segments of the vagina. On the right is added an extra 'cell', 30 μ in height, which represents the height of the epithelium on the surface of the body.

in the solvent in which they were injected in preference to passing into the body fluids. This may be perfectly explicable in terms of chemistry and physics. It may be incorrect to assume that the œstrogen itself enters into any particularly close relationship with the tissue at the site of injection regardless of what that tissue may be.

I am about to publish in the *Proceedings of the Zoological Society* some observations which seem to show that a particular sub-system within an animal —for example, a feather-germ—which uses or is affected by œstrone, may really have in itself the power of stocking up with the hormone. It presumably accomplishes this in the time available between the giving of the dose and its removal or destruction. Zondek[2] has shown that for this substance, œstrone, this time may be very short—a matter of hours. The stock laid in may be changed (it has not been recovered to see whether its œstrogenic properties remain unaltered), but it lasts for days, or at least its very strictly localized effects do.

In view of the obvious importance of an understanding of depot-formation to the whole subject of hormonic physiology and the action of carcinogens and evocators, it seems that further information is required about (*a*) the possibly pseudo-œstrogenic qualities of arachis oil, in order that the experimenter
may be clear about all t
œstrogens actually present
the injection, and (*b*) the p
cise circumstances in which t
known œstrogens, and so p
haps other active substanc
do pile up at points in expe
mental material or in Natu
It is hoped to continue th
investigations in this Depa
ment.

Connexion between Carbol drate and Potassium Metaboli in Normal and Adrenalecto ized Animals

OF the different metabo
disturbances caused by adr
alectomy, the increase of pot
sium in the blood plasma
believed by some authorities
be the most important, wh
others have emphasized m
especially the disturbances
carbohydrate metabolism.
now seems possible, howev
to connect these two sets
metabolic disturbance, as l
been suggested earlier[1] and c
now be proved.

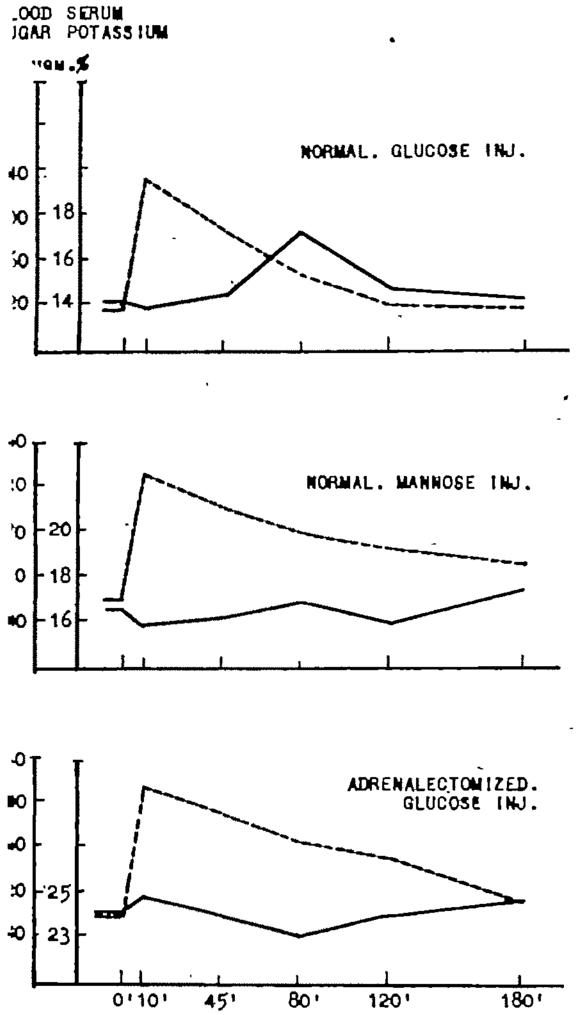
After intravenous injecti
of glucose (5 c.c. of 20 per c
solution in 1 minute to a cat
2–3 kgm.), the blood sugar ri
to about twice its normal le
and returns to normal after two hours. The same
true for galactose and fructose. Other hexoses, such
sorbose and mannose, and the pentose xylose, beha
quite differently: the sugar in these cases leaves t
blood much more slowly, and after two hours t
blood sugar is still 50 per cent higher than norm
Thus the different sugars behave in the same way
the transit between the blood and the tissues
between the lumen of the intestine and the epithel
cells during intestinal absorption. Those sug
which are selectively absorbed are also more rapic
taken up from the blood by the tissues than are t
non-selectively absorbed sugars.

After adrenalectomy, the changes in the behavio
of the different sugars in the blood are parallel
the changes in sugar absorption. Intravenou
injected glucose, galactose and fructose are n
taken up by the tissues just as slowly as the ot
sugars whose rate of leaving the blood has not be
changed by adrenalectomy. Just as the speci
process in the intestinal epithelium necessary for t
selective absorption of glucose, galactose and fruct
is lacking after adrenalectomy, so also is the speci
process by which these three sugars leave the blo
more rapidly than other sugars abolished.

It was then shown that injections of gluco
galactose or fructose caused a sudden increase

od potassium, while injections of other sugars used no increase. With the selectively absorbed gars, the peak of the potassium curve is reached ly when the sugar concentration in the plasma has eady begun markedly to decrease.

In adrenalectomized animals, however, there is no rease in plasma potassium after intravenous jection of the selectively absorbed sugars. These gars now react in the same way as the non- lectively absorbed sugars. The conclusion must be at there is a close connexion between the rapid take by the cells of the selectively absorbed sugars d the increase in plasma potassium. It seems st probable that the process which connects these o phenomena is a phosphorylation process leading the formation of glycogen or intermediary subnces. The possibility of such a mechanism has ently been stated by Conway and Boyle[2]. It uld then follow that it is this process which is king after adrenalectomy, thus causing the turbances both in carbohydrate and in tassium metabolism seen in adrenalectomized imals.



DOTTED LINE, BLOOD SUGAR; FULL LINE, SERUM POTASSIUM. AT 0′ 0·50 GM./KGM. SUGAR WAS INJECTED INTRAVENOUSLY.

The figures are examples of experiments which will be published in *Helvetica medica Acta*.

Anserine in Muscle: Possibility of Determination by Titration

SOME time ago[1], I showed that the buffering power of the non-protein constituents of rigor muscle between pH 6 and 7 could be largely accounted for by the sum of the buffering powers of the phosphate, carnosine, and lactic acid present. In the muscles of some animals, notably the horse, ox, and pig, these constituents accounted for more than 90 per cent of the non-protein buffering; in others, notably the rabbit, dog and fowl, a considerable residue of buffering—up to 26 per cent of the non-protein buffering of the muscle—remained unaccounted for. I suggested that this buffering might be largely due to anserine, which has a buffering range almost identical with that of carnosine, but reliable analytical data for anserine were not then available.

Zapp and Wilson[2] have, in the meantime, published a method of determining anserine, and give values for the anserine content of the muscles of various species which are of such a magnitude as to account completely for this unidentified buffering. Some instances are included in the accompanying table.

Species	Anserine equivalent of unidentified buffering (mgm./100 gm.)	Anserine reported by Zapp and Wilson (mgm./100 gm.)
Horse ..	50	17–48
Ox	110–240	38–144
Rabbit ..	325–495	223–502
Rat . ..	160–310	319
Dog .	270	212

The coincidence in the magnitude of anserine contents is extremely close, and although individual muscles vary widely the conclusion is justified that the unidentified buffering does represent buffering due almost exclusively to anserine.

The determination of residual buffering (that is, after deducting that due to phosphate, carnosine and lactic acid) may, therefore, serve as a rough guide to the amount of anserine present in muscle; it will certainly serve as a true guide to the upper limit of this substance present, for the actual titration of the muscle extract is accurate, the determination of phosphate is accurate, and the determinations of lactic acid and carnosine are reasonably so. The whole determination can be carried out on the extract from 10 gm. of muscle in a few hours (as compared with the several days needed for Zapp and Wilson's method) and many samples could be examined together.

It is proposed, when the opportunity offers, to evaluate the possibilities of the method by carrying out parallel analysis by Zapp and Wilson's method and by the titration method.

Isolation of a Catalytically Active Flavoprotein from Liver

WE have obtained from pig liver a flavoprotein in highly purified form which catalyses specifically the oxidation of aldehydes to their corresponding acids. The prosthetic group of this enzyme is flavinadenine dinucleotide. In the presence of acetaldehyde the enzyme is rapidly reduced to its leuco form, and the leuco form is autoxidizable in air. The mechanism of the catalysis, therefore, involves a cycle of reduction of the flavoprotein by the substrate followed by oxidation of the leuco form by molecular oxygen or any other suitable hydrogen acceptor. One molecule of the enzyme catalyses the oxidation of about 550 molecules of acetaldehyde per minute at 38°. Our best preparations of the enzyme transfer 2700 μl.H_2 per mgm. protein per hour ($Q_{\text{methylene blue}}$ 2700). The flavinphosphate content of the preparation as determined by direct estimation is 0·17 per cent. There appears to be some coloured grouping other than flavin which is associated with the enzyme molecule.

The above enzyme is not identical with xanthine-aldehyde oxidase either of milk or liver.

Synthesis of Myristicin

ALTHOUGH it is now many years since myristicin was first isolated from the oils of nutmeg and mace, its synthesis has not previously been recorded. Its constitution was established by H. Thoms in 1903[1] as 3-methoxy-4 : 5-methylenedioxy-1-allylbenzene, a molecule suitably orientated for its use as the starting point in the successful syntheses of cotarnine by Salway[2] and by Becker and Decker[3].

Allylation of pyrogallol 1-methyl ether gave,
good yield, a mixture of two liquid monoallyl eth
(I and II) which were separated by fractional d
tillation and characterized by the preparation
their 3 : 5-dinitrobenzoates (m.p. 111/2° and 13
respectively). I (most probably 1-hydroxy-2-allylox
3-methoxy-benzene) readily rearranged on pyroly
to give 3-methoxy-4 : 5-dihydroxy-1-allylbenzene, a
this on methylenation with methylene iodide a
anhydrous potassium carbonate in acetone (Perk
and Trikojus[4]) gave a 30 per cent yield of pu
myristicin (b.p.$_{0\cdot1}$ = 95–7°). The synthetic produ
was characterized by the preparation of dibrom
myristicin dibromide (m.p. 127–8°), *iso*-myristic
(m.p. 43·5°) and dibromo-*iso*-myristicin dibromi
(m.p. 158·5°). The melting points of all three co
pounds were not depressed by admixture with t
corresponding derivatives prepared from a specim
of natural myristicin isolated from oil of nutmeg.

The other monoallyl ether (II) did not give t
expected 2 : 3-dihydroxy-4-methoxy-1-allylbenze
after pyrolysis, but a mixture which, on methyle
tion and subsequent bromination, yielded mai
dibromo-myristicin dibromide. This rearrangeme
is being further investigated.

Our thanks are due to Dr. T. G. H. Jones, of t
University of Queensland, who kindly supplied t
oil of nutmeg.

Points from Foregoing Letters

X-RAY photographs of zinc insulin crystals in several immersion media have been obtained by D. Crowfoot and D. Riley. The wet crystal unit cell is found to be a moderately expanded version of that previously found for the air-dried crystals. Preliminary calculations show that the striking differences in the X-ray intensities given by the different crystal structures is to be correlated mainly with a reorientation of the molecules relative to the crystal axes which takes place on drying.

A number of cloud chamber photographs of cosmic ray particles have been taken by H. J. J. Braddick and G. S. Hensby under 30 m. of London clay. Most of the photographs show mesons, some show electronic showers. In five photographs out of 2,300 there is evidence of the simultaneous passage of two penetrating particles, and these are interpretated as associated mesons.

A. W. G. Kingsbury and J. Newton Friend report that the rare mineral greenockite (cadmium sulphide), seldom found in England, has been discovered in small quantity as thin layers in blende near Chewton Mendip. A. W. G. Kingsbury also describes a new locality for small quantities of fluorite in a disused quarry near Axbridge.

RESEARCH ITEMS

acteria of the Throat and Nose

AN account of the micro-organisms, the normal acterial flora, found in the nose and throat of persons ving in London and south-east England, some of hom were repeatedly examined over a period of ven years, is given in a report by Drs. Edith traker, Bradford Hill and R. Lovell, published by e Ministry of Health (Reps. on Pub. Health and ted. Subjects, No. 90. H.M. Stationery Office. s. net). The inquiry, which lasted from 1930 until 937, included repeated swabbings of volunteers from mong the staff of the London School of Hygiene nd Tropical Medicine, and of boarders in a boys' ublic school. Swabbings were also occasionally aken from inmates of the Royal Hospital School, reenwich, of an orphan home, and from members f the clerical staff of the Ministry. The work shows at of any large group of adults living in an urban mmunity between 20 and 40 per cent will usually t any one time be carrying a pneumococcus in the asopharynx, between 5 and 15 per cent a hæmolytic reptococcus, between 40 and 80 per cent the so-lled influenza bacillus, and between 5 and 20 per nt the meningococcus of cerebro-spinal fever. The eumococcus and the meningococcus were less equent in women than in men. The pneumococcus as found more frequently in cold damp weather an during hot dry periods, while the reverse sociation tends to occur with the hæmolytic reptococcus. The last-named organism shows a arp rise in prevalence in boys' boarding schools in sociation with outbreaks of tonsillitis. Neither the eumococcus nor the influenza bacillus shows any ose association with the fluctuations in mortality ttributed to influenza. Observations made on ersons suffering from colds tell strongly against the iew that the acute infectious cold is caused by any f the bacteria studied. Dr. Rosher contributes a ction on the frequency of the influenza bacillus in e trachea of unselected cases without respiratory isease coming to post-mortem examination; this rganism was found in 27 per cent of such cases.

arkings on Fossil Bones

ONE of the side-lines of investigation which variably leads to interesting and sometimes to portant indications of the make-up of a prehistoric una is the study of the markings upon bones. ones may be fractured or marked by contemporary uman beings, by animals and by various kinds of eathering and chemical action; and as a rule areful scrutiny reveals not only the agency, but in e case of animal markings perhaps even the species ncerned. Not much attempt has been made to stematize the distinctive characters of markings as guide to other workers, but in an excellent paper, piously illustrated, Pei Wen-Chung discusses s experience with bones from a series of sites in hina ranging from Pliocene to historic times ("Le le des animaux et des causes naturelles dans la sure des os", *Palæont. Sinica.* N.S., D., No. 7, 938). He describes the characteristic appearance of arkings caused by the gnawing of rodents of ifferent kinds and by carnivores, the striations due the scratchings of carnivore claws, vermiculations which are sometimes puzzling, and the indications of chemical action or the effect of water. Not the least useful section of his paper deals with examples of markings which, although due to other agents, might well be mistaken for human artefacts. Such errors of interpretation may easily be made by workers not familiar with the variety of markings which may be made by animal or physical agency.

Barnacle Communities

F. HIRO, in a survey on the barnacle communities at the Madarai Pier in Korôru Island, Palao (Palao Tropical Biol. Stat. Stud., No. 4), deals with the distribution and orientation of four species of Tetraclita and one of Chthamalus on vertical concrete piers. The various species show a clearly marked vertical zonation, Chthamalus occupying the highest zone, and extending to high-water mark. Where channels are cut under the pier, the Chthamalus show a marked tendency to avoid the parts where light and currents are strongest, while the Tetraclita species do not show this effect. Finally, in the centre of these cuts where light is weak, most barnacles are orientated at right angles to the current so that they can, by twisting the body through 90°, feed readily in a current coming from either direction, while those near the ends of the cuts tend to be orientated towards the light.

Bacterial Synthesis of an Eye Colour

THE diffusible substances *v*+ and *cn*+, which are essential for pigment formation in eyes of Drosophila individuals dominant for these genes, can be formed by recessive *vbw* insects cultured on starvation diet. E. L. Tatum (*Proc. Nat. Acad. Sci.*, 25, 486–497; 1939) now also finds that under suitable conditions certain bacteria synthesize a substance which has the activity of *v*+. All the present evidence indicates that the product from bacteria is identical with *v*+. An unidentified Bacillus species in the presence of tryptophane, can produce this substance, which is soluble in water and ethyl alcohol but insoluble in acetone and chloroform. Like *v*+, this substance is transformed into *Cn*+ when introduced into *vbw* flies.

Polyploidy in the Salamander

G. FANKHAUSER (*J. Hered.*, 30, 377–388; 1939) finds that the somatic chromosome number of ***Eurycea bislineata*** is 28. Of 134 larvæ examined, 13 were triploid with 42 chromosomes and 2 were tetraploid. The larger cells and pigment pattern allow the polyploid larvæ to be tentatively identified. The tetraploids were weaker and retarded in growth. Among 311 individuals of Triturus five were found to be triploid.

Fluorination of Phosphorus Halides

THE fluorination of phosphoryl trichloride and phosphorus tribromide has been studied by H. S. Booth, S. G. Frary, and F. B. Dutton (*J. Amer. Chem. Soc.*, 61, 2934, 2937; 1939). The phosphorus compounds were treated with antimony trifluoride, with bromine or antimony pentachloride as catalysts, or in the case of phosphorus tribromide with dry calcium fluoride. In this way the new compounds dibromomonofluorophosphine $PFBr_2$ and monobromodifluorophosphine PF_2Br were obtained from phosphorus tribromide. $PFBr_2$ is a colourless liquid (b.p. 78·4°, f.p. −115·0°), PF_2Br a gas (b.p. −16·1°, f.p. −135·8°), both hydrolysed by atmospheric moisture, decomposing slowly into PF_3 and PBr_3 at −78°, reacting with mercury with liberation of phosphorus, and combining with bromine to form, probably, $PFBr_4$ and PF_2Br_3. From the fluorination of phosphoryl trichloride by the same methods, gaseous PF_3 (b.p. −39·8°) and phosphoryl difluoromonochloride POF_2Cl (b.p. 3·1°, f.p. −96·4°), and liquid phosphoryl monofluorodichloride $PFCl_2$ (b.p. 52·9°, f.p. −80·1°) were obtained. All these substances are colourless and do not attack glass when dry.

Mercuric Halide Complex Ions

WHEN $HgCl_2$, $HgBr_2$ and HgI_2 are dissolved in solutions of the corresponding alkali metal halides, it is known that complex anions are formed. These have been represented as $HgCl_3'$, $HgBr_3'$, HgI_3', whilst evidence has been submitted for the existence of $HgBr_4''$ and HgI_4''. A. B. Garrett (*J. Amer. Chem. Soc.*, 61, 2744; 1939) has determined the solubilities of mercuric bromide and iodide in the corresponding potassium halide solutions. The solubility of mercuric bromide in pure water at 25° was found to be 0·0170 mol./1000 gm. water. The solubilities of mercuric bromide can be accounted for on the assumption that the only complex ion formed is $HgBr_3'$. In the case of mercuric iodide, however, an additional reaction is probably present, namely the formation of HgI_4'' in appreciable amount. The amount of $HgCl_4''$ is negligible; but the solubility of mercuric chloride in low concentrations of chloride solutions is anomalous. This is accounted for on the basis of polymerization of mercuric chloride to the order of 10 per cent. The free energies of formation of the complex ions from mercury halide and halide ions are given in gm. cal. at 25° as: $HgCl_3'$ −1700; $HgBr_3'$ −365; HgI_3' +430; HgI_4'' −2100.

Structure of Potassium Molybdocyanide Dihydrate

The substance potassium molybdocyanide dihydrate $K_4Mo(CN)_8, 2H_2O$, is one of the more familiar examples of compounds containing eight atoms or radicals bound to a central atom. The configuration of the MX_8 group has not previously been established with certainty in any single case, although the cube and the square Archimedean antiprism have been regarded as geometrically plausible. J. L. Hoard and H. H. Nordsieck (*J. Amer. Chem. Soc.*, 61, 2853; 1939) have shown by X-rays that the $Mo(CN)_8$ polyhedron is a duodecahedron with eight vertices and triangular faces. It can be described as the figure outlined by the vertices of two interpenetrating bisphenoids orientated in the same way as the positive and negative tetrahedra of a cube. Although required by the space group to possess only a plane of symmetry, the complex ion in the crystal approximates to the symmetry of one of the point groups.

Raman Spectrum of Gaseous Methylamine

THE literature on Raman effect contains very few researches on gases or vapours because of the difficulty of procuring good spectra at comparatively low pressures and with relatively short exposures. It is, therefore, extremely interesting to find that new technique has been developed by Kirby-Smi and Bonner (*J. Chem. Phys.*, 7, 880; 1939) whic by using a light source of high intensity, a lar scattering volume, and a spectrograph camera wi a large aperture, gives satisfactory spectra of ga at a pressure of approximately three atmosphe after an exposure of from three to six hours. De for gaseous methylamine are given and compar with those of Kohlrausch (*Monatsh. Chemie*, 349; 1936) for the liquid. The most noticea difference between the spectra is in the position the N-H valency vibrations near 3400 cm.$^{-1}$; in t liquid they are at 3312 and 3372 cm.$^{-1}$, whereas t gas shows them at 3360 and 3470 cm.$^{-1}$. These lar differences are attributed to the formation of hydrog bonds between neighbouring NH_2 groups in t liquid. For C-H vibrations, on the other hand, t largest difference between gas and liquid is 12 cm. Whereas all methyl compounds should possess on two vibrations characteristic of C-H bond stretchin methyl halides exhibit three, and gaseous meth amine is found to have four. Their origin is given a double Fermi resonance (*Z. Physik.*, 71, 250; 193 between a fundamental near 2840 cm.$^{-1}$ and t infra-red bands at 1460 and 1426 cm.$^{-1}$. The appe ance in gaseous methylamine of a hitherto unrecord displacement of 781 cm.$^{-1}$ is explained as due to N-H bending vibration, on the grounds that such vibration in the liquid would be sensitive to hydrog bonding and association.

Determination of Stellar Diameters by Interferometer

A PAPER was formerly published (*Mon. Not. Ro Astro. Soc.*, 99, 141) by Fürth, Sitte and App which proposed a modification of Michelson's stell interferometer that would enable it to be used ev when there were strong air perturbations. Tw independent papers have now appeared (*Mon. N Roy. Astro. Soc.*, 99, 9; October 1939) by P. Lacrou and J. A. Carroll, both of which criticize the efficien of the apparatus. Lacroute shows that in the modifi form suggested, even if fixed fringes are formed, th is, fringes insensible to movements of the Michels fringes, they would be utterly useless for the dete mination of stellar diameters. He shows, howeve that they are not insensible to movements of th Michelson fringes, and offers a tentative explanati of the reason why the authors of the original pap thought they observed stability, though he admi that the explanation may be conjecture, becau some of the experimental details could easily missed by anyone reading the description. Carr shows that they drew an incomplete analogy betwe a ruled grating illuminated by plane waves and th Michelson fringe system, because the displacement the Michelson fringes, in the focal plane of th observing telescope, does not correspond to a simp translatory motion of a grating, but to a translati and also a rotation, about an axis parallel to t rulings, of the incident light. For this reason th secondary system must move through the sa number of fringes as the primary Michelson syste He also tested the secondary fringes to see if th were less liable to disturbances than the Michels fringes, and found that the claim could not substantiated. It appears from the criticism Lacroute and Carroll that the apparatus for th elimination of strong air perturbation effects of no use for that purpose.

THE EVOLUTION OF THE STARS

By F. HOYLE AND R. A. LYTTLETON,

ST. JOHN'S COLLEGE, CAMBRIDGE

ROF. G. GAMOW has recently discussed in NATURE[1] the consequences of recent developents in nuclear theory on the problem of stellar olution. In the light of the exact knowledge that now available of a large number of nuclear retions, it is possible to decide which processes rise importance at the densities and temperatures evailing in the stars, and on this basis trustworthy timates have been given for the rate of liberation subatomic energy. These results, which are the tcome of laboratory investigations, furnish the athematical theory of internal constitution of the ars with a new equation that enables the luminosity a star to be calculated by direct methods. The formation so obtained has been utilized to attempt resolve the many paradoxes and discrepancies countered in discussing the general problem of llar evolution. All this recent work has been thoritatively summarized by Gamow with great arity and understanding in the article referred to ove. It is therefore with some surprise that we d that Prof. Gamow concludes his article with the pression that these new developments practically lve the problems of stellar evolution. This seems us to be so far from being the case that some rther discussion of the claims of nuclear theory as e main factor in stellar evolution would be desirable.

In the first place, it should be noticed that the plication of nuclear theory in its present state evitably leads to a result at least as embarrassing any of the questions that it might possibly resolve. r the theory maintains that no synthesis of atomic clei from hydrogen is possible within the stars cept for the very light elements. This would imply at the stars can no longer be regarded as the ilding place of the heavy elements, which must ve formed before they became part of the star—indeed they ever were formed. Now although such onclusion does not itself constitute a logical condiction, it seems to us to present such overwhelmg difficulty that it is much more reasonable to nclude that the basis of nuclear theory is in need revision rather than that the heavy elements were t formed by synthesis. On the other hand, many vestigators seem to have accepted the former sult as satisfactory, and in particular Gamow has oceeded to make it the basis of a theory of the red ant stars.

Secondly, Prof. Gamow apparently regards the nclusion that various classes of stars should be of ally different ages as a natural one. Thus the t that the present theory leads to a life-time for tain massive stars of order 10^{-3} the life-time of sun is not regarded as a difficulty at all; indeed is merely supposed that this is the case and the ory remains unquestioned. In point of fact, it is essential part of the theory as proposed by Gamow at all red giant stars are considered as of very ent formation, since the presence of lithium, etc., required to enable them to radiate with their posed low internal temperatures.

Now if all the stars could be regarded as single autonomous bodies, it would be difficult to dispute the validity of these views by direct means. But it so happens that the frequent occurrence of binary systems enables a simple test of the theory to be made, for in the case of binary stars both components must be of comparable age. It is immediately clear that the well-known difficulty concerning the relative emission per unit mass of the components of double-stars must remain in any theory that appeals only to the internal properties of the stars, although by making very artificial assumptions in Gamow's theory some of these discrepancies might be avoided. For example, it would require as a general result that the less massive components of binary systems form with a hydrogen content differing systematically from that of their companions. In certain cases this would lead to even more dubious initial conditions: thus, whilst Sirius must have formed with high hydrogen content, it would have to be assumed (according to the more generally accepted theory of degenerate matter) that the companion formed almost solely from heavy elements for it to have been practically exhausted during the whole of its existence. Such a solution of this difficulty could scarcely be regarded as satisfactory even if there were no other objection to the theory described by Gamow.

It should be particularly noticed that the foregoing suggestion assumes that the components have not evolved by fission, for this latter process (even if it were dynamically satisfactory) would clearly lead to two stars of closely similar compositions. We have been able to show, however, that to produce close binary systems, periods of order 5×10^{14} years are necessary[2]. Thus the existence of spectroscopic binary systems in which one component is a red giant or any highly luminous star presents an immediate contradiction of the theory given by Gamow. Moreover, there seems to be a general tendency for the mass of binary systems to increase with decreasing separation.

While on the subject of fission, it is perhaps only proper to point out here that although the mathematical investigations of the development of rotating fluid masses clearly demonstrate that binary stars cannot be generated by fission[3], many astronomers do not yet seem to have realized the physical significance of the mathematical results. As a consequence of this there are still many who 'believe' in the fission theory. But as will be seen, even an appeal to fission could not save Gamow's theory of the red giant stars, in addition to which it would raise afresh the difficulty of the relative emissions of the components in binary stars. Even if some process of break-up of a single star led to a binary system, it is evident that the components must have similar chemical compositions, while in close binary systems consisting of a red giant star and a class *B* star, Gamow's theory would require the red star to be the less massive component on account of the mass luminosity relation. But observation shows that in such pairs the giant star tends to be the more massive component. This is the case, for example, in the three stars υ Sagittarius, *VV* Cephei and ζ Aurigæ. Thus it seems that no matter from what angle we approach the questions raised by the observed properties of binary systems, the paradoxes already recognized by astronomers must remain in one form or another.

However, quite apart from the foregoing objections to the constructive portion of Gamow's article, it is very noticeable that no reference is made to the wide class of dynamical features that is associated with the stars. This, of course, is the direct result of attending only to the internal physical properties of the stars; but the dynamical features we have in mind are altogether too marked to remain unaccounted for in a satisfactory theory. Thus such questions as the formation of individual stars, and of binary and multiple systems, together with the general increase of mass with decreasing separation, and the observed approximation to equipartition of energy among the stars seem to present the real key to any theory of stellar evolution. An internal theory can give no explanation for the correlation between peculiar velocity and spectral class or the observed tendency for massive stars to lie in the galactic plane, features that must be related to the previous history of the stars.

It has been customary during recent years for investigators on stellar evolution to devote attention to internal constitution with little or no regard for the dynamical features. It appears that Prof. Gamow has followed essentially in this tradition and therefore confined his article to the modifications effected by the introduction of modern nuclear theory. Thus, in dealing with the properties of variable stars, no attempt is made to account for the three distinct periodicity groups comprised by stars of periods of order half a day, four days and 300 days. These variables also show a marked preference as rega spectral class, the first being largely of classes *B* a *A*, the second of *F* and *G* and the third of class Moreover, the two short-period groups exhibit most remarkable property in that none of them, o of more than two hundred available exampl possesses a close companion, whereas about one st in five of normal stars of similar spectral classes d possess a close companion. On the other hand, lon period variables appear to possess a normal co plement of companions. The first and third types a stars of moderate luminosity and show no pronounc galactic concentration, whereas the variables intermediate period, the Cepheids, are strongly co centrated to the galactic plane and are among t most luminous known stars. Thus it is clear th very remarkable dynamical properties are intimat connected with even the different types of variabili and therefore that purely internal considerations a most unlikely to prove capable of elucidating t nature of the connexion.

From these and many other dynamical qualiti associated with various types of stars, it appears us that Prof. Gamow has over-estimated the imp tance of nuclear theory in the problem of stel evolution. Indeed, in our opinion nuclear physi has very little to add to the results already co jectured by astrophysicists, and can merely serve confirm these conjectures, a typical instance bei the mass-luminosity relation itself. Finally, we wi to point out that although the present article consi largely of criticism, we have discussed elsewhere number of the questions raised[2], and it has be found that purely dynamical considerations may sufficient to provide a natural explanation of ma of the difficulties mentioned in this article.

SCIENTIFIC AND INDUSTRIAL RESEARCH IN CANADA

THE twenty-first annual report of the National Research Council of Canada includes the report of the president, with reports of the various divisions and of co-operative investigations, together with the financial statement and appendixes listing the publications of the Council and papers published by members of the staff and holders of research grants during the year.

Under the Division of Biology and Agriculture a good deal of attention has been devoted to plant hormones, and a simple method of treating seeds with plant hormone chemicals has been developed in which a carrier is utilized, either an inert dust such as talc or a seed disinfectant such as an organic mercurial or copper carbonate. It has also been found that a very small amount of hormone when added to the treated solution greatly reduces or entirely prevents the injury of seed in treatment with formaldehyde for control of smut disease. A joint project with the Dominion Forest Service and the Department of Agriculture dealing with forest tree breeding is to some extent an outgrowth of these plant hormone investigations, since the discovery of a method of inducing wood cuttings to root more freely has opened up new possibilities in th direction, particularly in the propagation of rapi growing and disease-resistant trees. Further wo on plant hormones has been carried out under associate committee on this subject, and the Divisi of Chemistry has given a good deal of attention the synthesis of a series of homologues of α-naphth acetic acid, as well as developing an improved meth for the synthesis of α-naphthylacetic acid itself. Oth work under the Division of Biology and Agricultu has been concerned with grain research, including t standardization of an experimental baking test f wheat, experimental malting equipment and metho for barley, food storage and transport, including t effect of freezing treatment and rate of freezing the quality of frozen poultry, beef, pork and mutt and a survey of packing plants exporting Wiltshi bacon. The Division has also co-operated with t Dominions Department of Agriculture in the develo- ment of hybrids between wheat and the Agropyro or wheat grasses with the object of obtaining larg seeded drought-resistant grasses for western Canad and some work has been carried out on the effect phytohormones on bacteria and yeast.

The Division of Chemistry has examined the otors involved in the preparation of rennet casein itable for the manufacture of plastics, particularly ttons, and the highly efficient packings for fracnating columns and scrubbing towers designed the laboratories are now being developed in forms ecifically suited for larger scale operations. Active ntact has been maintained with the laundry and eaning industries of Canada, and the Division has so co-operated with the Sub-committee on Textile ecifications of the Canadian Government Purasing Standards Committee. An investigation of e laundry cleaning process with sodium hypolorite has been concluded, and work carried out the efficiency of wetting compounds and mixtures r use in the first or 'break' operation where orough wetting of the fabrics is of importance. he magnesian products laboratory of the Division as made available to the Canadian metal industry tter refractories and a wider range which can be tained from Canadian materials, notably the oduct of high-grade refractories from dolomite. Various barks have been investigated as a source tannin for the leather industry, and in the rubber boratory much work has been done on bonding bber to leather, particularly the application to e manufacture of automobile engine mountings a bonding material previously developed in the boratory. Numerous tests have been made of ch materials as paints and textiles on behalf of the anadian Government Purchasing Standards Comittee, while a process for the preparation of organic ercury derivatives, particularly alkyl mercuric alides and other salts used for seed disinfection, has een developed. Use of the disinfectants in the form a dust consisting of an inert carrier adapted to here to the seed has also been studied, and Canadian entonites or talc proved satisfactory as carriers, the ust being equal in disinfecting power to the best ported products. Work on synthetic resins has een extended to cover the formation of polymers om chloromethyl compounds.

The Division of Chemical Engineering has a wind tunnel for testing aeroplane models and streamlined locomotives and other equipment in which air resistance is important, and a model-testing basin in which similar problems in regard to water can be investigated. Safety tests are continually made of domestic oil, gas- and gasoline-burning appliances. Five ship models were tested during the year in the towing basin in connexion with the design of private and Government vessels. Numerous aircraft instruments, gasoline and lubricating oils have been tested for various branches of the Government service.

In the Division of Physics and Electrical Engineering an increasing amount of standardization and testing work of all types has been carried out. In addition to studies of the heat insulation properties of building materials, the development of a suitable thermostat for refrigerator cars has received much attention. Thousands of aircraft castings have been examined by X-ray methods; and the cathode ray compass and direction finder, detection of fire through haze, estimation of forest fire hazards, vibration in aircraft and ultrasonic generators for depth sounding are other problems under investigation.

Steps were taken during the year to reorganize the Division of Research Information and establish a Section of Research Plans and Publications, one function of which is to provide technical secretarial services for the president and some of the associate committees. Stress is laid in the report on the organization of an Associate Committee on Medical Research. The Associate Committee on Grain Research has outstanding achievements to its credit in the solution of problems relating to bread wheat. Studies of the drying of tough and damp wheat have established the conditions under which this can be done without injury to the milling and baking quality of the grain. Other investigations dealt with seed injury by fungicidal treatments, effect of formaldehyde treatment on the growth of wheat and prevention of heating of damp grain in storage.

R. H. THURSTON: ENGINEER

CENTENARY CELEBRATIONS

THE celebration of the centenary of the birth of the distinguished American engineer, Robert H. hurston, held at Cornell University on October 25, as the occasion for the delivery of several addresses in hich tribute was paid to the great influence Thurston ad on engineering education and progress, and also eference was made to the part the engineer should ake in the solving of social and economic problems. he addresses were given in the Bailey Hall before n audience of more than a thousand persons, which cluded many of Thurston's old students and elegates from no fewer than sixty universities and stitutions in the United States, Great Britain, anada, France and Germany.

When inaugurating the proceedings, Dr. E. E. ay, president of the University, said that in the nse and hurried living of this twentieth century of urs, it is difficult and at times well-nigh impossible keep in clear view the importance of the really urable values of life. No corrective for this difficulty so sure as the occasional review of the qualities of leadership in great men. War-racked and depression-ridden though this world may be, the force of individual character remains undiminished. As the years of Thurston's active service recede, his contributions to the upbuilding of Cornell lose none of their impressiveness, while the lives of the men who went out from his tutelage continue to attest the strength of his mind and spirit.

After speeches in which Thurston's training at Brown University, and his work as a naval engineer and as an instructor at the United States Naval Academy had been recalled, Dr. H. N. Davis, president of the Stevens Institute of Technology, Hoboken, dealt with "Pioneering in Engineering Education at Stevens". Thurston had joined President Henry Morton at Stevens in 1870, when thirty-one years of age, and he brought to bear upon the problem of an engineering curriculum an original mind, a wide outlook and great force of character. There were two aspects of his work at Stevens, said Dr. Davis, that seemed likely to be permanent parts of the Thurston tradition in engineering education. First he seems to have invented the idea that a mechanical laboratory is an appropriate part of an American Engineering School. It is, of course, difficult in 1939 to realize that in 1870 this idea had to be invented.

Thurston's conception of such a laboratory was a threefold one; first, it should be a place where a student could become practically acquainted with working machinery; secondly, it should be a place where staff and students, working together, might by research make important contributions to the progress of engineering; and thirdly, it should be a place to which industry could bring its problems, whether of testing, of design and development, or of a still more fundamental nature.

For his laboratory Thurston invented testing machines, and as a servant of industry the laboratory played an important part when few, if any, industries had their own plant for routine testing. From "a schedule of charges" dated 1877, and signed by Thurston, it appears that a test on the "autographic recording testing machine, of strength, ductility, resilience, and determination of elastic limit, elasticity, homogeneousness of structure and amount of internal strain, with strain-diagram and record" could be had for three dollars. A trial of a steam engine or boiler could be made for twenty-five dollars plus sixty cents an hour for field and office labour.

Thurston also had a conception of the fundamental position in mechanical engineering of the two great fields of the study of the properties of materials and of the problems of power. Further, he foresaw the position engineers were likely to occupy as industrial executives, and himself set an example to others by taking part in public affairs. He exemplified, concluded Dr. Davis, "a conception of the scope of the service of the engineer that may well be our inspira tion and ideal for many years to come".

The fourth address was by Dr. W. F. Durand, hi biographer, who dealt with Thurston's eighteen year 1885–1903, at Cornell, and the concluding addres was by Prof. S. C. Hollister, dean of the College o Engineering, Cornell, and was entitled "Looking t the Future". After referring to the great materia developments since 1868, when engineering was fir taught at Cornell, Prof. Hollister asked, "What ha all this development done to human living?" Ne problems have arisen of vast social import, and t every phase of the scene, as he saw it, the enginee has a direct relation. He must be prepared to cop successfully with changes wrought by scientific an technical advance; he is concerned with productio processes and organizations; he is involved i problems of management, finance, public relation and government. It seems clear that he is bound t be involved more and more in the social and economi problems that lie ahead.

There is but one way of preparing young men fo our expanding technical future, namely, to trai them broadly and deeply in the fundamental science Some feel that engineers are not trained in civi consciousness and usefulness. Prof. Hollister thinks i only fair to say that the whole educational field await with interest convincing testimony that any give curriculum accomplishes this very desirable en Civic consciousness is a matter of community attitud rather than the result of studying any system o subjects. The surest way to provide the right community attitude is to prepare men and wome thoroughly for the parts which they are to play i the community. Cornell for many years has, i varying degrees, been functioning in this direction.

MANUFACTURE OF RADIO SETS FOR EXPORT

ACCORDING to the *Electrical Times* of November 16, British manufacturers are often criticized for not studying the requirements of overseas markets. The reason for much of this criticism is easy to understand, as the conditions in the home markets of several of our international competitors are very similar to those in overseas countries which are large purchasers. To take a case in point, consider the export of radio sets.

It is common knowledge that, in the early days of foreign competition in the radio market, foreign competitors took the lead. In the United States, for example, where a widespread short-wave broadcasting system was employed, manufacturers found that little modification to the standard models was required to make them suitable for reception to distant parts of the world. British manufacturers had no similar home experience to rely on. Several of the leading firms in Great Britain have now built up an export market for models which have been specially designed for overseas use and have achieved success in winning back lost ground. The General Electric Co., Ltd., has an organization of a world-wide network of completely equipped and technically staffed branches which offer great facilities for before and after sales service. Its experts travel the world studying reception conditions and problems at first-hand. In one tour alone Nigeria and Siam, Canada, India, New Zealand and Hawaii were visited, th total distance traversed being 50,000 miles. As a resul of the valuable information obtained great improvements in design were facilitated and many specia tests, which every G.E.C. overseas radio receiver no undergoes as a matter of routine, were devised.

Illustrations are given in the *Electrical Times* o the apparatus used in the special laboratory an factory tests on the sets in the 'humidity cabinet'. I this cabinet any required temperature and relativ humidity can be obtained and also the cyclic variations representative of tropical climates. Syntheti resin insulation, used for wave change switches, an rubber insulation receive special treatment in respec of both electrical and mechanical properties. In th artificial ageing test, specimens are subjected to hig temperatures in an oxygen atmosphere and must remain unimpaired after 200 hours' treatment. One o the tests for the mechanism of switches is to perfor satisfactorily 50,000 operations. A motor-drive reciprocating mechanism operates the switch durin the test. An instrument is also used to check th moisture content of wooden components to ensur that seasoning has been thorough. During th manufacture of mica condensers all the operation are carried out in a filtered air-conditioned room an glass screens protect the condensers from th operator's breath.

FACTORIES AND THE BLACK-OUT

THE many problems which have been encountered by those responsible for blacking-out factories in the present emergency were discussed in some detail at a meeting of the Chemical Engineering Group of the Society of Chemical Industry which was held in the rooms of the Chemical Society, Burlington House, London, on December 8. Mr. H. W. Cremer presided and opened the discussion, during which it was manifested that the actual blacking-out in itself did not produce the only difficulty. It has been found hat there are psychological and physiological effects on the workers, to say nothing of difficulties which have been introduced in the matter of ventilation. As regards the latter, the need for blacking-out factories has rather revealed that there is yet a great deal to be learned concerning the ventilation of factories in normal times, and the suggestion that his problem should be gone into more thoroughly is likely to be taken up by the Committee of the Group.

Mr. Cremer directed special attention to the problem of ventilation and its effect upon night workers, plus the effect of reduced lighting, stressing hat factories should be designed normally—and reorganized in present circumstances—with an appreciation of the fact that they have to house human beings as well as machines.

Mr. L. W. Robson, of Messrs. Nobel's Chemical Finishes, Ltd., speaking of the actual physical problems of blacking-out, strongly advocated the extensive use of paint, which he said can be applied apidly, is cheap and permits of uniform lighting conditions being obtained in the factory by day and by night, so that the efficiency of workers is not affected by changes in degree of illumination prior o and after black-out times. He admitted that the objection to this is a considerable increase in the lighting bill, but claimed that the objection is not so great as is sometimes made out. For example, in the case of buildings camouflaged with paint or netting, the daylight illumination is often reduced to an extent which necessitates artificial lighting during the daytime. Again, in many engineering shops where fine work is done, bench lights are in constant use, irrespective of daylight or darkness.

Remarking that oil-bound distempers, oil paints and bituminous paints are all suitable for blacking-out purposes, Mr. Robson spoke also of the use of aluminium paint for vertical windows, which improves the general brightness of a room by its eflection, but it must not be used on roof lights, as it increases glint.

An alternative to the complete obliteration of windows is the use of complementary lighting, the colours chosen being usually orange and blue. This ystem is based on well-known optical principles and entails the conversion of the windows to blue filters which will not pass orange light, and the use of lamps which give orange light free from any blue ays. The lamps may be sodium vapour lamps or gas-filled lamps made of suitably coloured glass, or ordinary lamps suitably lacquered. It was emphasized that photographic workers find no difficulty in working in red or green light of much lower intensity than is afforded by this scheme. (Incidentally, there was some difference of opinion among the speakers on this matter, some referring to trouble with their workers owing to this form of lighting and others saying there had been none, after a short period of time.)

Mention was also made of fluorescent and phosphorescent paints. Fluorescent paints or pigments, of course, give off visible light when excited by invisible ultra-violet light but have no after-glow when the excitation is removed, whereas phosphorescent paints continue to glow after the exciting source is removed. The pigments used in these paints are based on zinc and cadmium sulphides. They must be incorporated in a special medium, and the paint, when applied, should be protected with a final coat of clear medium. These paints are obtainable in a variety of colours and glow brilliantly when used with a 'black' lamp.

There are, of course, numerous applications for such paints under black-out conditions, and it is recommended that where a paint is required for direction indicators in a building which will be suddenly blacked out when a warning is received, it should be of the zinc sulphide type, because of initial brightness. On the other hand, outside signs, or doorways which must be found after many hours of darkness, should be painted with an alkaline earth paint.

Dr. G. E. Foxwell said he had found that vertical retort tar, when heated under certain conditions with lime, had been found excellent for blacking out roof lights and was very resistant to moisture, showing no signs of peeling off. Mr. F. A. Greene remarked that he had discovered this many years ago, and added that with good quality tar there was no need for treatment with lime.

A number of other points were raised during the course of the discussion, in which some twenty speakers took part, and many of them concerned the extreme difficulty of complying with the regulations and maintaining manufacturing efficiency. For example, there are the numerous cases of large furnaces and the problem of blacking out the glow from them. In one case, where a complete black-out was effected, the men could not continue their work for more than two hours at a time. Some relief was obtained with a system of louvred ventilation combined with a degree of light restriction, but it was extremely costly.

One speaker remarked that where a complete black-out had been 100 per cent effective, it was practically 100 per cent defective as regards the workers, who objected to the orange lights and blue windows. The lighting of goods sidings at night has also entailed much difficulty and restriction of operations, but permission has been given by the authorities for a modified form of lighting and an arrangement of switches by which all lights can be instantly extinguished should a warning be received.

Another difficulty referred to was that of the increase of temperature in buildings under black-out conditions, due to reduced ventilation in consequence of windows having to be kept closed to prevent emission of light.

SCIENCE NEWS A CENTURY AGO

The Birmingham Mechanics' Institution

On December 17, 1839, an exhibition was held at the Mechanics' Institution in Birmingham and a correspondent wrote to the *Athenæum*, "It contains more than one hundred thousand articles arranged very tastefully in the rooms belonging to the Institution. Ornithology is the richest department in Natural History: there is a very perfect collection of British birds belonging to Dr. Lloyd; and a beautiful collection of the varieties of humming bird, prepared by Mr. Heywood, a mechanic of Coventry, who devotes his leisure hours to the cultivation of Natural History. . . . The departments of Geology, Mineralogy, and Crystallography are rich, but not extensive. . . . The models of engines, machinery, etc., are not so numerous as they were in the Grammar School during the visit of the British Association, but among them are some articles which were not then displayed, especially some lathes of admirable construction and great power."

Fossils from the London Clay

On December 18, 1839, Richard Owen read to the Geological Society a paper "On the Fossil Remains of a Mammal, a Bird and a Serpent, from the London Clay". Until a few months previously the highest organized animal remains known to exist in the London clay were those of reptiles and fishes. In collections at Ipswich and Woodbridge, however, had been discovered teeth of a quadrumanous animal, of Cheiroptera, plantigrade and digitigrade carnivora, and of a species probably belonging to the marsupial order. These had been found in the London clay of Suffolk. To these Mr. Owen had been enabled to add remains of a new and extinct genus of pachydermatous mammals, of a bird and a serpent. The first of these had been discovered in the cliffs of Studd Hill, near Herne Bay, by Mr. W. Richardson and consisted of a small mutilated cranium, about the size of that of a hare, containing the molar teeth of the upper jaw nearly perfect, and the sockets of the canine. The remains of birds consisted of a sternum with other bones, and a sacrum, both found at Sheppey. The sternum forms part of the collection of fossils formed by John Hunter. One of the specimens of extinct species of serpent was likewise in the Hunterian collection and consisted of about thirty vertebræ. This also was found at Sheppey.

Light from Plants

At a meeting of the Botanical Society on December 20, 1839, reported in the *Athenæum* of December 28, Dr. Willshire communicated all that was then known with respect to the evolution of light from plants, a subject which had recently attracted some attention on the Continent, but which was first observed in *Tropaloium majus*. The subject was divided into two portions, namely, light evolved from dead and living vegetable structures, and it appeared that wood rotted in the air never shines, it being requisite to be buried in the earth, when the sap is contained within it. It was observed that this effect takes place only in the months of July and August, in warm dry weather, never in damp. Several plants were mentioned as evolving light during the putrefactive stage, among others, mushrooms, potatoes, etc.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on before the dates mentioned:

TEACHER OF ENGINEERING SUBJECTS—The Principal, Luto Technical College, Park Square, Luton (December 20).

TEMPORARY DISTRICT OFFICER to the Essex War Agricultur Executive Committee—Executive Officer, East Anglian Institute Agriculture, Chelmsford (December 22).

TWO UNIVERSITY-GRADUATES (male and female) to teach Engli in a Lycée in Ankara—The British Council, 3 Hanover Street, W. (envelopes marked 'Turkey') (December 27).

CIVIL ENGINEERING ASSISTANTS in connexion with the Haweswate Scheme—The Secretary, Waterworks Offices, Town Hall, Manchester (December 28).

CHIEF EDUCATION OFFICER to the County Borough of Doncaster—The Town Clerk, 1 Priory Place, Doncaster (December 31).

SUB-LIBRARIAN at the University of Cape Town—The Secretar Office of the High Commissioner for the Union of South Africa, Trafa gar Square, W.C.2 (December 31).

SCHOOLMASTER OFFICERS in the Royal Navy—The Directo Education Department, Admiralty, S.W.1 (January 2).

TEMPORARY MASTERS to teach Mathematics, Physics and Applie Physics—The Headmaster, Oundle School, Oundle.

RESIDENT ENGINEER to the Witham and Steeping Rivers Catchmen Board—The Engineer to the Board, 50 Wide Bargate, Boston, Linc

LECTURER IN MECHANICAL ENGINEERING in the Witwatersran Technical College, Johannesburg—Messrs. Frank Ross and Co 9 Fenchurch Avenue, E.C.3.

UNESTABLISHED EXAMINERS in the W/T, Instrument, and Gener Engineering Branches of the Aeronautical Inspection Directorate the Air Ministry—Inspector in Charge, A.I.D. Training Schoo Brandon Street, Bristol 1.

SOCIAL PROBLEMS OF WAR-TIME EVACUATION

AN admirable review of the problems arising out of the sudden redistribution of popula- n involved in the evacuation of the priority asses at the outbreak of war is given in a broad- eet on the "Home Front" recently issued by litical and Economic Planning (P E P). So far, wever, there has been little evidence of any g-term thinking on these problems. Moreover, hough a number of individual business firms pear to have acted on Mr. Harold Macmillan's a for a considered review of the whole policy evacuation, and returned part at least of their ntral offices from the country into London or her larger cities, there are no signs that the portunity of revising and improving evacuation rangements is being utilized by the Government. On the contrary, so far from evidence of funda- ental thinking about the essential problems, ich have such a close bearing on the efficiency our war effort and morale, everything indicates at evacuation questions are being dealt with as y-to-day exigencies, with little attempt at the ng-range thinking which would avoid many of e dilemmas at present involved. Until recently, serious effort has been made to consider the oblems of visitation between parents and ildren, whether of parents to the evacuation eas or of children to their homes.

The acute problems which evacuation has raised the sphere of education are indeed realized, and belated attempt is being made to deal with the fficulties of education of the children remaining the evacuated areas—difficulties which a firmer d more definite policy at an earlier date might ve very considerably reduced. Even in the ception areas, the essential social welfare work s been left to voluntary social service organiza- ns, and local welfare committees, and no organized effort made to meet the needs of the children or adolescents out of school hours, away from home influence and with the long nights of winter already here.

The absence of such national direction and co-ordination not only places heavy burdens on local authorities, but also is apt to engender a feeling of injustice in the reception areas, making for further attrition of the whole evacuation scheme. Its absence leads to grossly unfair burdens falling upon the teachers themselves, who are often bearing much heavier financial charges as a result of the disruption of their home life, apart altogether from the heavier responsibilities and the inroads on their private life. The effect of such factors on the efficiency and morale of the teaching staff is very far from receiving the attention it deserves.

The basis for any long-range policy which is to grapple effectively with the difficulties must be an impartial scientific examination of the facts. It is accordingly encouraging to find that an attempt at a scientific survey of evacuation problems has been made in at least one district. A preliminary report on this investigation, which has been made possible by a grant from the Liverpool Council of Social Service, and carried out by the University of Liverpool Department of Social Science in co-operation with the Liverpool University Settlement under the direction of Dr. Gertrud Wagner, has been published by the University Press of Liverpool.

The report is based on 356 interviews in the neighbourhood of the settlement, and is preliminary to a fuller investigation; but nevertheless it indicates clearly that the difficulties in working the evacuation scheme are due to four sociological and psychological facts. The family—

the basic unit of society—is broken up in the evacuation area or may be gravely disturbed in the reception area, with serious economic and psychological difficulties. For most working-class mothers, the main or even sole purpose in life—bringing up and working for their children—disappears when they are evacuated. Each social group in society has its own standards of living and behaviour, but under the evacuation scheme different groups are forced to live together.

The main difficulties discovered are listed under six heads. There is that of the mother in adapting herself to the new environment, and of the host in accepting the intrusion of someone with a different standard of living. Separation of the parents from the children frequently leads to a serious emotional problem. The provision of additional or better clothing for the children and the cost of fares to visit them present urgent economic problems, while lack of selection in placing the children and sometimes poor organization are a fourth set of difficulties. Removal of children from the reception areas by parents without due consideration or consultation, and the departure of the mother from the home leaving behind members of the family unused to managing on their own, apart from the economic difficulty of keeping two homes going, are further causes of trouble.

These difficulties are not to be dismissed lightly, and the report makes a number of suggestions for meeting them. The appointment of trained social workers in each reception area to visit the homes regularly and give informal advice to the hosts on the care of the children and their education, and to straighten out difficulties the hosts may have had with the children, would solve many problems. Propaganda by wireless talks or in the press advising mothers against visiting their children too soon after their removal from home or against being unduly influenced by letters written in a moment of depression would be of service, while social workers could also assist in diverting heavy demands on the mothers for clothes to organizations dealing with such matters.

Accurate knowledge in advance of the available accommodation in a reception area is essential, and also arrangements for medical examination of evacuees to secure diversion to camps or hostels of those unsuitable for private houses. Requisitioning of empty houses in the reception areas to deal with emergency cases is also recommended, as well as some regulation to prevent the removal by parents of their children without the consent of the appropriate educational author

It would be unfair to expect of a prelimin report more than recommendations to mitig the difficulties, and this investigation, wh incidentally, by illustrating the admirable con bution which the universities can make in so research, underlines the recent appeal of National Union of Students for liberal support the Government even in war-time, only indica the wide field open for both private and offi investigation if an adequate and resolute pol is to be evolved. Urgent as is the need for s investigations, there are matters in which im diate action is called for. The question of holid has to be faced boldly and frankly, whether fr the point of view of the children, the teachers the hosts. The construction of school camps ne expediting, and a large expansion of that p gramme would alleviate many difficulties. T school medical services must be reorganized time to cope with any of the usual spring epidemi and strenuous efforts made to safeguard, in rec tion as well as in evacuation areas, not mer teaching and discipline but also the whole syst of milk, medical, nursing and dental servic which largely came to an end when the scho were closed.

One recommendation of the Liverpool rep would appear to be fundamental. Unless it known what numbers of children are to stay the country, reorganization of education in t reception areas, the opening of temporary scho and hostels, the building of camps, and the relea of the local schools from the shift system can proceed. Parents should at least be requested authority to make a definite choice and compell to abide by it.

Education is, however, only one aspect of ci life which has been disturbed by evacuation, a even here the problems are far from being confined those of school-children. In technical and universi education, problems have been raised which a equally acute even if less in magnitude. Profou disruption has been experienced in professional li and the recent acceptance by the Ministry Health of the proposals of the special Adviso Emergency Hospital Medical Service Committ for reorganization of the emergency medical s vice covering the hospitals, the medical staffing first-aid posts and the position of specialis indicates that in one important sphere at lea the opportunity of readjustment and reconside tion has been utilized.

Much more, however, might be done to correct fects in our emergency plans, given the willing- ss of authority to recognize such defects and cept constructive criticism. Measures to facilitate e resumption by adults of family life might well sist in guaranteeing the maintenance of our onomic strength and the expansion of industry cessary both for the output of munitions d the buoyancy of the national finances. As r. Macmillan suggested, even now large industries d Government departments could consider return to normal, or at least locate their units accordance with long-range plans in which all e risks and disturbances are weighed. The rrender by Government departments of schools d hotels so hastily commandeered should not ly diminish some of the evacuation difficulties the educational field but also remove a potent use of public discontent.

The importance of this factor must not be overlooked. In the absence of any attempt to redress the mistakes made in this matter of commandeering—to repair the disturbance of education and destruction of equipment which occurred although alternative office accommodation was available, or to do justice to those who have suffered from the commandeering of hotels and other buildings—a lack of confidence is engendered alike in the impartiality and the integrity of the central administration. There can be no mistake as to the firm determination of the nation to see war through to victory, or as to the equally firm determination to have the utmost competence in its conduct. Refusal to acknowledge and rectify mistakes, or to accept constructive criticism, only undermines the good will and morale upon which the struggle and, above all, the unprecedented redistribution of population and activity make such tremendous demands.

THE LIFE-WORK OF MY FRIEND F. W. H. MYERS

Iuman Personality and its Survival after odily Death

y Frederic W. H. Myers. Vol. 1. Pp. xlvi+ 00. Vol. 2. Pp. xx + 660. (London, New York nd Toronto: Longmans, Green and Co., Ltd., 939.) 36s. net.

FREDERIC W. H. MYERS died in Rome in 1901, just as this century opened; but he ft behind him a mass of writing which was fterwards edited and published as two volumes n "Human Personality", reviewed by me in NATURE of June 18, 1903 (68, 145). These books epresent for all time his real life-work, that for hich he was willing to live laborious days; they epresent what he genuinely conceived to be a essage of moment to humanity; they are his gacy to posterity; and in the light of the facts ontained in them he was willing and even eager o die.

Death Myers did not dread. That is true; and is clear and happy faith was the outcome entirely f his scientific researches. The years of struggle nd effort and systematic thought had begotten in im a confidence as absolute and supreme as is to e found in the holiest martyr or saint. By this I ean that it was not possible for anyone to have more absolute and childlike confidence that eath was a mere physical event. To him it was n adversity which must happen to the body, but t was not one of those evil things which may ssault and hurt the soul.

Myers would have described himself as one who walked by sight and knowledge rather than by faith, and his eager life-long struggle for knowledge was in order that he might by no chance be mistaken. To some, conviction of this kind would be impossible—they are the many who know not what science is; to others, conviction of this kind seems unnecessary—they are the favoured few who feel that they have grasped all needed truth by revelation or by intuition. But by a few here and there, even now, this avenue of knowledge concerning the unseen is felt to be open. Myers believed that hereafter it would become open to all.

The doctrine which Myers arrived at after years of study is that each individual as we perceive him is but a small fraction of a larger whole, is as it were the foliage of a tree which has its main trunk in another order of existence. The metaphor constantly breaks down, as all metaphors must sooner or later; for some purposes it would seem better that the tree should be inverted; and the adjective "subliminal" contains no reference to what is beneath, except in the sense of foundation and support; in every other aspect the subliminal is probably the more real and more noble, more comprehensive, more intelligent self, of which the supraliminal development is but a natural and healthy and partial manifestation.

The products of the subliminal are to be regarded as "higher" in a definite sense than those of the supraliminal. The supraliminal is that which is the outcome of terrestrial evolution, and so is able to manifest itself in a planetary manner; the subliminal has a cosmic existence, which may play a part in terrestrial evolution hereafter, but at present only shows signs of doing so, as, for example, in the supernormal uprushes which are known as the inspirations of genius; signs which may be taken as anticipatory of the course of evolution in the future.

In this way sleep, death, genius, insanity, hysteria, hypnotism, automatism, clairvoyance, and all other disintegrations, abnormalities, and supernormalities of personality, fall into a consistent comprehensive scheme; and it is the object of the work to elaborate this hypothesis and to unify all these strange features of human personality, features which have so long afforded an exercise alternately to resolute credulity and to blatant scepticism, and have so perennially perplexed mankind.

The central feature of the book is the "Scheme of Vital Faculty", an elaborate and comprehensive scheme, which will be found in the second volume between pages 505 and 555, a scheme on which Myers bestowed a great deal of thought and which I saw emerging from his pen at the time he was writing it. It constitutes a synthesis or conspectus of the whole, wherein each vital faculty is displayed under the aspect appropriate to the three heads, somatic, psychic, and pneumatic; or, as he styled them, supraliminal, subliminal, and spiritual.

How far such a scheme as this soars above the range of the orthodox science of to-day is apparent from the fact that few of the faculties catalogued and classified in it, beyond those in the first category, are as yet generally recognized as existing at all. A few from the second or middle category are coming into recognition—such suggestion, hyperæsthesia, psycho-therapeuti and telepathy—but the greater part even of t second list is still only on the outskirts of recogniz knowledge; while in Myers's view it is the thi and at present wholly ultra-scientific catego which lies in the path of future knowledge a development, and constitutes the most pregna portion of his message to mankind.

It is not to be claimed that these volumes w convince a reader of the survival of personali beyond bodily death if he was previously hosti to or otherwise fortified against such an ide Perhaps they will convince nobody. The ma object of the work is not edification and finalit but stimulation to inquiry; and convictions any value are seldom attained by mere readin they can only be formed by soaking one's mind a subject for years, by "continually thinking un it", as Newton said. As the outcome of such process, it became Myers's undoubted belief th intelligence and human personality persist beyo bodily death; and that, between the two stat or conditions of being, intercommunication thou difficult was not altogether impossible. But th conclusion of his has been popularly seized an over-emphasized until to many of his conten poraries it seemed that an easy credulity on th point was his characteristic attitude. Nothi could be further from the truth. Easy credulit does not lead to a life-long labour and evolution a comprehensive scheme such as this.

It would have been an appalling blunder have allowed such a book as this to fade out remembrance and become impossible of attainme by the younger generation, especially at a ti like the present. OLIVER J. LODGE.

OLD AND NEW ASTRONOMY

One Day Telleth Another

By Stephen A. Ionides and Margaret L. Ionides. Pp. xii+324+31 plates. (London: Edward Arnold and Co., 1939.) 10s. 6d. net.

MANY books have been published on descriptive astronomy for general readers, ranging from simple stories intended to interest children in the starry heavens to surveys of celestial fact and theory requiring the intelligent attention of mature minds to comprehend them. All such works tend to remove the heavens farther and farther from the earth, though to early peoples these were complementary parts of a living universe. The quaint figures which, in ancient times, marked t positions and forms of the zodiacal and oth constellations have disappeared from celesti globes and maps, and the goddess Urania has lo her place among the other muses.

Mr. Ionides and his daughter have revived t human spirit in ancient astronomy and have th given new life to its presiding genius. In so aspects, their book is reminiscent of "Astronomic Myths", by J. F. Blake, which was based up Camille Flammarion's "History of the Heavens' and describes early observations and conceptio relating to the earth and the universe associate with the affairs of life and with religion. Th work, and R. A. Proctor's "Myths and Marvels of stronomy", were published more than sixty years go, and are unknown to most of the present-neration of observers and readers of astronomy. The volume before us, written in the light of dditional archæological knowledge and astron-mical discovery, should appeal to a wide circle f readers more interested in humanistic aspects f science than in simplified accounts of new ientific knowledge—factual or speculative.

The subjects of the chapters are time, days, easons, the sun, the moon, eclipses, planets, omets, calendar, precession, constellations, naviga-on, geography, astrology, and cosmology; and n each of them old and new ideas are lucidly ombined and interpreted. The field of inquiry and thought is vastly more extensive now than n the times of the astronomers of Babylonia, gypt and Greece, but the intelligence of man has ot undergone similar expansion; and if philosophers of those ancient days could be reincarnated ow, they would see clearly, in Mr. and Miss onides' book, how present knowledge has developed out of their own contributions in a natural equence.

What would be strange to such philosophers is he great extension of the field of observation endered possible by the use of optical and other ientific instruments. But though we now measure ime and angle in seconds, the division of the odiac into twelve signs of 30° each was the origin f the division of the circumference of a circle nto 360°. As to the use of the number twelve, he late Dr. J. K. Fotheringham, the great authority n ancient astronomy and chronology, showed that t was used by the Sumerians to divide the day, and that the Babylonians afterwards divided day and night each into twelve hours. It was natural or the Chaldeans, with whom sixty was an mportant number in their system of numeration, o use it in subdividing the hour into sixty minutes, nd, later, into sixty seconds. The construction of accurate instruments to measure seconds of time nd angle came long after these units had their origin.

It is of interest to trace in a single chapter of this volume how the old and new astronomy are combined; and that on the sun may be appro-riately used as an example. The sun as the source nd benefactor of all life on the earth was the essential idea of the religions of many ancient peoples, and its worship was particularly dominant n Egypt. The first truly monotheistic religion was that founded by Ikhnaton, whose followers worshipped the sun as a symbol of the one and nly God—"Thou disc of the sun, Thou living God: there is none other beside Thee". In his Moses and Monotheism", Freud, shortly before his death, traced the transition of Ikhnaton's teaching from Egypt into Palestine with the Exodus of the Hebrews. Long afterwards, Ezekiel was lamenting that the women of Israel were weeping for the departure of Tammuz—the sun-god of the Sumerians, Babylonians and Assyrians. Out of these ideas came the Greek gods of the sun—Phœbus and others—but these deities then became objects of inquiry, and Aristarchus used geometry to estimate the distance of the sun from the earth. About 1000 B.C., Zoroaster identified the "God of Light" with goodness, and evil with darkness, and called his god Mazda, the name given to-day to a well-known type of electric lamp. Because the study of light belonged to theology, it was encouraged when other branches of physical science were snares of the devil. So we are led up to modern times, with the discovery of helium in the sun by Sir Norman Lockyer (whose name, however, is not mentioned), and its isolation twenty-six (not twenty as stated) years later by Sir William Ramsay from the mineral cleveite.

Continuing their romantic story, the authors proceed to some modern aspects of solar physics. Referring to terrestrial influences of sunspot activity, they state that wet and dry seasons are associated with the sunspot cycle, but this simple relationship has never been established. Prof. A. E. Douglass's studies of the rings in sections of tree-trunks, though of scientific importance, cannot in any way be accepted as proof of such a connexion; while the statement that there were no spots on the sun during the seventy years from 1645 to 1715 requires more confirmation than that given in "a letter from a London astronomer". From sun-spots the authors pass to the chromosphere, prominences and the corona, and they point out that the form of the corona at minimum epochs of solar activity is roughly represented in the "ring with wings" found throughout Babylonia, Assyria and Egypt. Many motor-cars to-day carry upon their bonnets a form of the Egyptian ring with wings. The chapter ends with a reference to Dr. B. Lyot's photographs of the solar corona and prominences without an eclipse and to the construction and use of Hale's spectroheliograph.

The other fourteen chapters of the book similarly combine the archæology of astronomy with modern knowledge of the heavens. The pattern presented to the human mind to-day is made up of the warp and woof of time and thought from many stages of civilization; and, though the ultimate design be still unknown, the loom will continue to weave the threads of knowledge into a fabric which worthily represents man's endeavours to understand Nature and his place in it.

R. A. Gregory.

STRATIGRAPHICAL STUDIES OF CALIFORNIA

Miocene Stratigraphy of California
By Robert M. Kleinpell. Pp. ix+450+22 plates. (Tulsa, Okla.: American Association of Petroleum Technologists; London: Thomas Murby and Co., 1938). 22*s*. 6*d*.

THE geological pioneer in any newly explored area distinguishes certain broad stratigraphical units, based primarily on lithic characters, and secondarily on the contained fossils. He correlates these units roughly with those on the familiar time-scale. As subsequent research, in the course of years, is extended in area and intensified in each locality, palæontological evidence becomes increasingly important, and problems of interpretation and correlation arise. Does a well-marked lithic change, say, from shale to sandstone or limestone, correspond to a definite moment of time, or did it take place earlier here than there? What faunal aggregates may be trusted as exact age-indexes (zone-fossils), and which give ecological evidence (facies-fossils)? How can time-divisions based on Foraminifera be correlated with those based on Mollusca, echinoids or vertebrates? All these problems are faced by Mr. Kleinpell in his revision of the Miocene of California.

The Neogene of California is disposed in tectonic basins, about a dozen in number, from Humboldt in the north to Los Angeles in the south. About half-way along is the Paso Robles basin, and in this lies the Reliz Canyon, which provides the author with his type section. The aerial photograph serving as frontispiece shows the area to sufficiently arid to give a practically continuo exposure; but one must admire the painstaki determination with which so many successi associations of Foraminifera were collected, iden fied and tabulated. Such labour would scarce have been thought of without the stimulus whi the search for oil has given to the detailed stu of Foraminifera.

The first half of the text consists of discussio on matters of correlation, which are not only great importance to all who are concerned wi the Tertiary geology of the Pacific slope of Nor America, but also to all geologists interested the problems outlined in the first paragraph of th notice. The author introduces a new series divisions (with new names) which he believes have a precise age-value, replacing such we known terms as Monterey Shale, which will alwa keep their broad stratigraphical and physiograp ical usefulness, but are misleading when taken corresponding to the same duration of tin wherever they occur. This first part is illustrat by maps, sections and tables, the largest of whi occupy a pocket in the cover. Bibliographic references are very full. The second half is systematic catalogue of Foraminifera, illustrat by twenty-two plates. There do not appear be any new species.

This should be the standard work on the Mioce of California for years to come. A. M. D.

IN PRINCIPIO ERAT VERBUM

An Ecological Glossary
Compiled by J. Richard Carpenter. Pp. ix+318. (London: Kegan Paul and Co., Ltd., 1938.) 15*s*. net.

THERE are two ways of compiling a glossary: the critical and exclusive, and the complete and impartial. Dr. Carpenter adopts the second method. Its advantage is that it brings all the varying terms and expressions together and reveals in a striking way the inconsistencies and unresolved conflicts found in a comparatively new science such as ecology. Its disadvantage is that it conceals the dead words and meanings among the living. A compromise, relegating obsolete words and meanings to smaller print or brackets seems desirable and might be suggested for future editions.

Ecology, like genetics and other recent disciplines in biology, applies to both plants and animals. It is interesting to examine its termin logy from this point of view. Evidently botan was the predominant partner at the time th special terminology was in process of formatio as all the basic terms for associations appear t rest on plant criteria. Only in such ancillar matters as bird-watching do we find an infiltratio of terms based on zoology. This may, of cours be due in part to the fact that the plant con stituents of a society are more fixed than th animal ones and less liable to wander out of th picture; but it seems probable that zoologica terms will bulk more largely in future edition The glossary shows certain inconsistencies in term which ecology shares with genetics, for example 'variation'; and Dzierzon's 'theory' or 'concept is just a fact.

The sight of more than three thousand technica xpressions brought together moves one to reflect their quality as language. The great majority ecological terms are from the Græco-Roman, which biology seems undivorceably if unhappily edded. They vary in sound from the not unleasing 'kalloplankton' and 'quaquaversal' to the pellent 'autephaptomenon' and 'necrocoleopterphilous'. It is at times a shock to meet a native ord, like 'plot', which appears sandwiched etween 'ploadostadion' and 'plotophytes'. Prof. lements, the noblest Græco-Roman of them all, credited with more than four hundred terms. he non-classical words are broadly international; ost abundant are German (translated), Spanish nd Portuguese; but French, Italian, Danish, orwegian, Afrikaans, Serbian, Russian, Magyar, rabic and Swahili words occur, together with me unidentified by the reviewer. One wonders it is wholly wise to use outlandish languages; hough they sound as a rule better than the Greek examples, they are difficult to check and thus lead to confusion; witness the entries under 'igapu', 'ygapo' (not cross-referenced), 'igaqu' (p. 228) and 'caagapu', all apparently equivalent to the 'rebalsa', or in plain English, flood-forest, of the Amazon.

The book, though not free from misprints, is well produced. In addition to 287 pages of glossary there are a useful introduction and a bibliography, while appendixes give tabular comparisons of the plant-sociological terms of opposing schools, and reprint important plant and animal regional maps Dr. Carpenter cites, wherever possible, the author from whom he takes his definition, with the date—a practice to be commended to all compilers of scientific glossaries. He has carried out his task in a painstaking and exhaustive way, going so far as to define 'foreshore', 'reprint' and 'peck-order'. The book will be popular in university departments and will prove a valuable basis for any later critical survey of ecological terms.

No. 13: he Refugee Question. By Sir John Hope Simpson. p. 32. (Oxford: Clarendon Press; London: xford University Press, 1939.) 3*d*. net each.

THE admirable series of Oxford Pamphlets on World Affairs, of which the first thirteen itles given above were published before the utbreak of war, have lost nothing of their alue on that score. The brief accounts they ive of current international topics will serve to ssist in the clear understanding of the events which orced Great Britain into war, and to strengthen he determination to bend all our efforts to uccess.

In the first pamphlet of the series, Sir Alfred Zimmern discusses the factors which have destroyed internationalism in the modern period, the necessity for applying moral standards to political relations, and the problem of adjusting the social and political habits and traditions of mankind to the conditions of the modern world. The optimism of 1919 failed to recognize the dimensions of the problem that lay before the civilized world. Sir Alfred insists that the problem which baffles and discourages us in 1939 has political, economic and moral elements. The last he considers is the most important; for, if least urgent, it is a permanent problem in all political life. The difficulties which have always attended this problem, for example, from the fact that politics is concerned with power, have been intensified by the enlargement of the rule of political life through the multiplication of international contacts, and also through the weakening of moral standards. While Sir Alfred does not believe it is possible to eliminate the tension between moral ideals and political realities, it is quite possible to lay down general principles of political conduct which afford sure guidance in particular circumstances as they arise.

In regard to the economic element, which is a long-distance problem of adjusting the social and political habits and traditions of mankind to the conditions brought about by the Industrial Revolution, Sir Alfred suggests that we should begin by finding the smallest change in our established social and political habits and arrangements which will enable mankind to reap the benefits of the age of power, abundance and interdependence. Determination of the least possible change, not the greatest possible change, would, by easing the strain on the ordinary citizen, make it possible to reap the benefits which science has placed within our power. In regard to formation of a new habit of mind to meet the requirements of our problems, it is sufficient that most of the citizens of the responsibly governed countries should be world-minded.

On the political side, Sir Alfred considers the political problem of Europe to-day is that of the political immaturity of the German people. Until that chronic condition has yielded to treatment, Europe will remain a politically backward continent, and the statesmanship of the democracies, which otherwise might be fully employed in breaking down prejudices surviving from outworn conditions and leading the European peoples into the larger world opened out to them by science, must be expended in counteracting or overthrowing a senseless militarism.

This pamphlet is followed by one on the British Empire by H. V. Hodson, in which the status of the different members of the British Commonwealth of Nations, the position of the Crown in Imperial relations, the question of Dominion neutrality in time of war, the co-ordination of defence, trade relations within and without the British Commonwealth, problems of migration and race are concisely and lucidly explained and discussed. This is followed by Mr. R. C. K. Ensor's account of Herr Hitler's disclosures of policy in "Mein Kampf" and of the extent to which this policy has so far been carried out. In addition to assessing future possibilities, Mr. Ensor briefly describes Hitler's theory of 'race', the doctrine of *Lebensraum* or 'habitat', and the scale of annexation prescribed for Greater Germany. In the fourth pamphlet, "Economic Self-Sufficiency", Prof. A. G. B. Fisher discusses the fallacies which underlie the policies of 'autarky' or economic self-sufficiency, the pursuit of which in certain countries has aggravated the economic problems of the world in recent years. In the fifth pamphlet, based on sections of the book "We Europeans", under the title " 'Race' in Europe", Prof. Julian Huxley demolishes the myth of racialism and shows that the theory of an 'Aryan race' is a myth. The violent racialism in Europe to-day is a sympton of Europe's exaggerated nationalism ; it is an attempt to justify nationalism on a non-nationalist basis, and to find a basis in science for ideas and policies which are generated internally by a particular economic and political system, are relevant only to that system, and have nothing to do with science. The cure for the racial mythology with its accompanying self-exaltation and persecution, is a re-orientation of the nationalist ideal and an abandonment of claims by the nations to absolute sovereign right Science is bound to point out the biologica realities of the ethnic situation and to refuse t lend sanction to the racial absurdities and th racial horrors perpetrated in the name of scienc Prof. Huxley states that all the facts are agains the existence in modern Europe of anything i the nature of separate human races. He also dea with national types, the Jewish question and th advantages of race mixture.

A seventh pamphlet, "Colonies and Raw Materials", by H. D. Henderson, discusses the value of colonial possessions to a metropolitan country especially as sources of 'raw materials'. Mr Henderson concludes that the industrial people of Europe, whether they possess colonies or not have no reason to apprehend any difficulty i obtaining tropical raw materials, or raw materials of any kind, in a peaceful world. One of th problems of world-economics to-day is the exces of supply of primary products over demand. While the supply of raw materials of most types is tending to increase more rapidly than before, the populations of the industrial countries are increasing more slowly and will soon probably decrease

The next pamphlet in the series (No. 8), by R. R. Kuczynski, examines in detail the so-called problem of *Lebensraum* or living space. Dr Kuczynski's survey of this problem of population leads to the conclusion that from an economic point of view Germany's living-space is more valuable now without colonies than it was before the War of 1914–18 with colonies. She does no require colonies to relieve population pressure in the mother-country. Her former colonies would not be in a position to provide her with foodstuffs they could only supply her with a negligible fraction of her requirements of raw materials unless forced labour were introduced on a gigantic scale. The return of her former protectorates overseas is demanded for military reasons and to exploit them at the cost of the 'natives'.

Other aspects of this question are discussed by Prof. J. L. Brierly in Pamphlet No. 12 ("Encirclement"), in which the political significance of the problem of *Lebensraum* is indicated. Prof. Brierly. pointing out the reality of encirclement, shows how nearly all European countries are in fact encircled, but the encirclement of which Germany complains is a defensive measure provoked by Germany's own aggressive measures and broken faith. A pamphlet by Sir Arthur Salter (No. 11 "The Dual Policy") largely summarizing his book "Security : Can We Retrieve It ?", outlines the policy pursued by the British Government since March 15, 1939, resting on the twin foundations resistance to force, and the constructive work of building peace.

MAGIC IN MEXICO

IT has been remarked by more than one observer of the population of Mexico that whether account be taken only of the indigenous inhabitants of purely Indian descent, who subscribe to the observances of the Catholic Church, or those of mixed blood be brought into the picture, it includes a large number who habitually, and as a matter of course, take part in ceremonies and ites which are either completely pagan or have been adopted into the local ecclesiastical calendar with no more than a veneer of Christianity, which barely covers and does not disguise their true character. In remarking on such observances, no reference is intended to the beliefs and customs of hose Indian peoples of Mexico who are as yet but little affected by European civilization, and of whom there is still a considerable number.

A record of some remarkable ceremonies of a magico-religious nature has been made recently by Dr. Robert Gessain in the course of an expedition to the Hidalgo State or Province of Mexico, on behalf of the École française de Mexico, to which reference is made in another column of this issue (see p. 1039). Although compelled by ill-health to return to Europe before his work was completed, Dr. Gessain was able so far to win the confidence of a suspicious people as to be allowed o witness the performance of a number of these ceremonies, and also to secure descriptive accounts of others which had not been performed for very many years. The observances, it is believed, or known in certain instances, have a wide currency, with local variation, among neighbouring Indians belonging to groups other than that with which he was concerned; but it was impossible, owing to the circumstance mentioned, for him to enter upon the comparative study, which is obviously an essential for fuller understanding.

The Indians among whom Dr. Gessain's researches were carried on are the Tepehua, a group numbering approximately six thousand, who live in the village of Huehuetla of approximately a thousand inhabitants, and the surrounding district, which falls within the respective borders of three States, or provinces, Puebla, Hidalgo, and Veracruz, and lies on the Atlantic slope of the high central plateau. The Tepehua are surrounded by villages of Otomi and Totonac; and although on lingustic grounds they have been assigned to the Totonac group, it is permissible to doubt whether their affinities with their neighbours have been defined with complete certainty. They have been visited by European observers on two previous occasions only—Frederick Starr in 1900, and Helga Larsen in 1934.

While participation in similar ceremonies, or rather their local variants, appears to be virtually universal among the Otomi, the number of Tepehua who take part regularly is about two thirds of the total, the strict Roman Catholics standing aloof. There is, however, a considerable marginal body which is prepared to take part in pagan ceremonial or Christian ritual indifferently. The mixed breeds, numbering about a hundred, being resident with a view to commercial interests only, take no part.

Owing to a variety of influences, the cult has tended to become something in the nature of a survival within the last twenty or thirty years. The sorceror-priests (*brujos*) are less numerous, and the performance of the ceremonies is now of a less extended character. Nevertheless, the cult is still full of vitality, as is shown by the amounts the votaries are prepared to pay the *brujos* for the performance of a ceremony, such as that of the opening of a new house, or in connexion with the birth of a child. The cult is said to flourish with most vigour in San Francisco (Veracruz), where Tepehua emigrants are numerous.

The ritual ceremonies are many in number. Of these, some, connected with the routine of cultivation, or the climatic cycle, are periodic; others are occasional and indeed, it was stated, had not been performed for twenty-five or thirty years. Again, the ceremonies may either be associated with an individual misfortune, such as an illness, or a collective disaster, such as a river-flood.

Dr. Gessain describes in detail a number of ceremonies, or magical practices, in which the services of the *brujos* are sought: the opening of a new house or sugar cane mill; the ceremony of the maize harvest or general harvest festival, in which the whole community takes part, and at which all *brujos* are present, but receive no fee; a ceremony in the dry season for the protection of the maize and the other crops from both drought and the depredations of birds and vermin; for the bees, this a fertility ceremony when an insufficiency of wax is being produced, wax being of more importance than the honey on account of its use for ritual purposes; the installation of a sorceror-priest; when the river floods, again a ceremony at which several *brujos* are present, and most or all the members of the community; for curing disease and ill-health; against epidemics; for curing sterility in women; at and after child-birth; to secure the fertility of young girls; for the dead and after death; and numerous enchantments to procure or retain love; to ensure fidelity in the married; to avert jealousy, and the like.

Without entering into an analysis of the details of the ceremonies, which Dr. Gessain describes, attention may be directed to certain characteristics which afford a general idea of the nature of the ceremonies. They usually include offerings and a sacrifice, normally a fowl or a turkey, which is decapitated by the *brujo*, either with his *machete*, or with his hands. Sometimes, especially when the ceremony is intended to secure a personal benefit, such as the cure of sterility in a woman, or at the installation of a *brujo*, the blood of the victim is drained into a vessel, and used to make the mark of the cross on certain parts of the body of the individual in question. The head of the victim, sometimes also the dismembered body, may be buried, but more often among the Tepehua, the victim is cooked for the sacrificial feast; or with the other offerings it may be thrown away in the river or buried. Among the Otami, of the village of San Gregorio, the offerings of food placed on the altar raised to the dead are thrown away at a customary place at the end of the village, instead of being eaten as among the Tepehua. It is essential that the meat for the sacrificial meal should be cooked and served by women who are not members of the household in which the ceremonies are being held, and this rule applies also to the women who perform the office of laying out the dead. The ceremonies are led by the *brujo*, or sorcerer-priest, who performs the sacrifice, supervises the laying out of the feast, censing the food and table with copal, and leads the dances and chants which make up the greater part of each ceremony, apart from the offerings, the sacrifice, and the sacrificial meal. Should a procession form part of the ceremony, as in that for rain, it is headed by the *brujo*.

The ceremonies take place at night, often lasting the whole night through. They usually take place in the house of the individual concerned, for example, when an illness is being treated, or in the death ceremonial; but ceremonies in which the whole community takes a part may take place in the house of one of the *brujos*, as, for example, happens at the celebration of the harvest festival. This is interpreted by Dr. Gessain as evidence for the survival of a hierarchy among the priests. Among the Tepehua of San Pedro a special house is set aside for the celebration of ceremonies in which the whole community is interested or concerned.

A fee is paid to the *brujo* for the performance of all ceremonies, except the communal harvest feast. The installation of a sorcerer-priest costs the candidate a fee of several hundred pesos, which is paid to his sponsor, under whose instru tion he has been for the preceding twelve month He also provides his sponsor's clothes, whic includes two scarves which have been woven b the women, strangers to the household, who a responsible for the preparation and serving of th sacrificial meat. These scarves must be woven an completely finished in the two days before th ceremony takes place.

It is interesting to note the relation of thes ceremonies to Christian ritual and concepts. Th harvest festival, for example, is held on Septembe 16, which is the feast day of St. Michael, as we as the national day of Mexico; and the ceremon for the protection of vegetation in the dry seaso takes place on Palm Sunday. Among the Otom of San Gregorio, at the time of the sowing of th seed, *munecos* (paper figures) are cut out in differen colours according to the nature of the crops. Thes with sacred flowers, a species of Dianthu which plays a prominent part in all ritual perform ances, are placed in the church. There is n Catholic priest here.

It is perhaps worth noting, though Dr. Gessai offers no comment, that at the sacrificial meal a the installation of a *brujo* thirteen places are lai on the table, of which the thirteenth place i smaller than the rest, and receives a half-portio at each service, of which there are four. Afte each service, the meat is taken from the plate and placed in two *ollas* or jars standing ready fo the purpose, prior to its consumption by th company.

Enough has already been said to indicate th function of the *brujo* or sorcerer-priest. It is remunerative office. Should such a ceremony a for example, the opening of a new house not b performed, any serious illness of an inmate whic may follow, or any misfortune, will be attribute to that fact. Such stress, indeed, is laid upon it that a *brujo* will often exhort the owner to borro the money (six pesos) rather than omit it.

The *brujos* of Huehuetla are five in number The initiate whose installation is described was man of about fifty years of age. In the ceremon three altars were erected in the house of th initiate, in which the ceremony took place. Th altars differ in size, and the largest is left standin after the ceremony to be the *brujo's* special alta for the remainder of his life. The head of th turkey which was offered at the ceremony, an with the blood of which he was marked with th cross, was buried in this altar. The altar is destroyed at a ceremony fifteen days after the *brujo'* death. During his lifetime it is always adorne with sacred flowers, paper figures and clay saucers Burning tapers appear on the altar only while ceremony is taking place. The crystal which h es for magical and divinatory purposes rests it in a clay saucer. This crystal occupied the allest of the altars at his initiation. Another operty of the *brujo* is his *idolo*. This is an tique statuette or figurine, which has been dug by the *brujo*, often at a great distance away. equently it may consist of no more than a head, which event it is completed in wood and is essed either as man or woman. This also rests the *brujo's* altar and is the object of a cult. me *brujos* may have several of these.

The *brujo* enters into relation with the spirit rld on several occasions and by various methods. the fertility ceremony of the bees he addresses he advocate of the bees", and at the very close the harvest festival on September 16 he sets his *idolo* and addresses a chant of invocation it. In the rain ceremony a procession is made a certain marsh and the *brujo* addresses the goddess of the marsh (*sirena della una*) a list of the offerings which are to be rown into the water; and she is implored to peal to "the Lord of the Sea" should she not ntrol water enough in the marsh to cause fficient rain to fall. Among the *munecos*, which e thrown with other offerings into the lake, is e in two colours in the form of a young boy nich is said to symbolize the *brujo* himself. One the most interesting examples of the relation the *brujo* to the spirit world is seen in the open-g of the ceremony for the harvest, when the rcerer-priest retires under the table, which is aped with a fibre mat, thus forming a species of lge. A cup of chocolate and a cake are handed him, and here he remains in communion with e spirits for the space of one hour. At the remony of the installation of a *brujo*, when offer-gs of food are being served, twelve times he fills vessel with cane spirit, and tenders it in the sture of offering, first above, then below, the ble before pouring it away into a bottle. When yone who is seriously ill has been cured by the nistrations of the *brujo*, he offers apologies to e dead of the family.

The star cult, which is a prominent feature of omi belief, has also influenced the religious ideas the Tepehua, while the cult of the moon appears the ceremony for curing sterility in women. is ceremony is addressed to the moon, as it is lieved that sterility is caused by the moon's anger.

The remarkable element in all these ceremonies, wever, is the liberal use of paper 'figurines', the *necos*, either decorative patterns cut in rect-gular sheets of coloured paper, or in silhouette, latter being most frequently employed for the man form. The decorative forms are conven-nalized, as is the human form; but usually it possible to recognize what it is intended to represent, especially in the flower and corn forms, while the symbol for agricultural operations is readily to be identified, when it is realized that it represents the furrow made by the plough. The representation of the stars is more formal, but starlight in the sky is clearly intended. The human form, both male and female, though conventional in attitude and characteristics, which conform to certain standardized patterns, is otherwise sufficiently realistic. Many of the more decorative *munecos*, especially those in which crops and flowers are represented, recall the European cut-paper ornaments of the Victorian age, which perhaps may have influenced their development. European influence, even in the representation of the human form, seems to be clearly indicated. This, however, is not a question which has been discussed by Dr. Gessain.

Starr records the use of bark paper, but this apparently is now used only by the Otomi. The Tepehua always use paper which they purchase from the half-breed traders, and use for no other purpose. The *munecos* are not used singly. Not only are several different patterns used in each ceremony, each with its special function, but also a large number of each are cut out and used in various ways.

The magical function of the *muneco* is varied. In certain instances it is little more than an amulet with apotropaic power, as for example, when it hangs across a road to bar the approach of an epidemic to a village. The idea that the *muneco* may act as a detergent agent seems to be present in the ceremony of healing the sick, when *munecos*, sacred flowers and a live fowl are rubbed over the body of the patient. When the fowl has been killed, it is wrapped in the *muneco* and the whole, including the flowers, is thrown in the river. That they may symbolize a spirit, human or other, is indicated by the *muneco* used in the ceremony for the dead, which takes place on the bank of the river a week after death. It represents the *brujo* trampling on the corpse to prevent the spirit of the dead man from returning, while in another, used in the ceremony to ward off epidemics, the *brujo* is represented dancing on a devil, presumably the spirit of the disease. In its magical use the employment of a representation of the human form recalls the power given the European witch and others by the use of a waxen image. When a woman seeks the help of the sorcerer-priest to gain influence over her husband, or to prevent him beating her, in the former instance *munecos* are given her to place secretly in his pillow. These represent him at her feet, or in prefiguration beneath her feet; and the images are sometimes duplicated to enhance the influence she will have over him.

Further, spirits which are not human may be conceived as actually embodied in the *muneco*. When in the ceremony for rain the participants return from invoking the Sirena, two *munecos*, one male and one female, accompany the procession and are carried as standards. Before they start, water is dipped from the marsh and scattered over and around them, and this is kept up at intervals as long as is possible along the road. They are the helpers, or ministers, of the Sirena, who have been charged to carry water for the fields, which will fall as rain. They are left hanging over t road at the entrance to the village, while othe have been left along the road.

Comparative study of this body of ceremoni which Dr. Gessain was unable to undertak but it is to be hoped is only postponed f a future occasion, would be of the great interest. The magical use of the human figu recalls, for example, the appliqué need work, showing European influence, of San B (Panama).

RECENT WORK ON EXPERIMENTAL PARTHENOGENESIS

BY PROF. A. D. PEACOCK,

UNIVERSITY COLLEGE, DUNDEE

IT is proposed here to outline some recent biological and cytological studies in experimental parthenogenesis. The rearing of reproductive parthenogones and parthenogenetic strains after experimental treatment has been achieved only once. The Russian worker, Astaurov[1], after subjecting unfertilized ovarian or newly laid eggs of the silk-moth, *Bombyx mori*, to increased temperature, obtained adults from which descended three successive parthenogonic generations. Out of 25,770 caterpillars only 11 were males. His work developed from Sato's[2] in Japan, adults of both sexes, males predominating, being obtained after the use of hydrochloric acid or other chemicals. As the female in Lepidoptera is the sex-determining sex, these different results are possibly due to the different agents affecting differently the sex-determining mechanism in the eggs, or to physiological conditions, for example, degree of maturity, in the different eggs.

The next most successful results are limited to frog parthenogones advanced enough to be sexed, only two cases being known. Twenty years ago Jacques Loeb, after needle-pricking of eggs, reared certain specimens which Parmenter[3] later sexed: 21 metamorphosed tadpoles—18 male and 3 female; 34 tadpoles—12 male (one metamorphosed), 2 apparently changing into males, 18 female and 2 of doubtful sex.

Cases of adult, or of metamorphosed, but unsexed parthenogones are also few. So early as 1907 Delage[4] reared metamorphosed sea-urchins and starfish, while, recently, Parmenter[5] obtained five metamorphosed tadpoles after needle-pricking, and Kasansky[6] reports his curious experiment by which healthy adult carp were reared from eg stirred in male human saliva.

Artificial parthenogones of worms Mollus echinoderms and amphibians attaining stages advanced as the larval are more numerous b still comparatively few (Delage[4]). Recent ad tions comprise the echiurids *Urechis cau* activated with dilute sea-water by Tyler[7], a *U. unicinctus*, for which Hiraiwa and Kawamu used ammoniacal sea-water (which gave the be results), shaking, or warm, hyper- or hypoto sea-water, or sea-water containing potassiu cyanide. The eggs of freshwater fishes a promising material, for those of pope, perc roach, bream and pike developed when Trifonov used water at 28°–30° C., or distilled, while ea embryos of pike developed after Kasansky's[10] u of diphtheritic serum, sugar, salt, warm wat onion juice and mustard, etc.

Recent mammalian work presents remarkal features. In 1927 Champy (see Pincus[11]) d covered an 8-celled stage in a virgin rabbit's ova cultured in rabbit plasma plus fowl embryon extract. In 1930 Pincus achieved astonishi success by taking unfertilized rabbit eggs from t Fallopian tube and culturing them *in vitro* plasma clot, or in serum, plus embryonic extract of 213 eggs 63·8 per cent developed, ranging fro the 4- to the 40-celled stage and even to t morula, the stages to all appearance resembli *in vivo* specimens. Results approaching the appeared also in Garufi and Oliva's cultures[12] rabbit eggs from ovarian follicles. Further, Pincu even obtained blastulæ by transplanting into t Fallopian tubes of pseudo-pregnant rabbits eg artificially activated by agents commonly used f invertebrate eggs—hypertonic solutions, heat a

ak acids. Previously, by such agents, Pincus
d Enzmann had induced second polar body
rmation and also that of two polar bodies
incus[11]).

Also of remarkable interest is Harvey's[13] success
parthenogenetic merogony. Centrifuged sea-
chin eggs (*Arbacia punctulata*) divided into
herical halves and quarters, and those without
clei, activated with hypertonic sea-water, de-
loped into blastulæ (one with 500 cells), one
nbryo without gut, anus or skeleton actually
ing obtained. Later successes relate to other
a-urchin species and to activation by mono-
romatic ultra-violet radiation.

Traumatic parthenogenesis has been further
ploited by Kling[14], who has made steel needles
ith points as fine as 1 μ, the diameter of a sperm
ad, and much finer than those hitherto used.
ith these and less fine needles he has activated
og eggs. But he has also induced activation
lely by applying pressure with a blunt instru-
ent, without membrane rupture. The activatory
motion of the sperm he regards as chemical, a
urely mechanical function being excluded because
much weaker developmental effect is produced
y a needle point of the same diameter as a
erm's despite the needle wound being of greater
ze. Further, pressure alone sufficing for activa-
on, he attributes the initiation of activation to
rocesses set in action by traumatization of the
g cortex, membrane rupture being unnecessary.

Regarding the chromosome constitution of
perimental parthenogones, Parmenter[8] has dis-
vered an interesting range of conditions in 26
og tadpoles; haploids numbered 10; diploids
(5 metamorphosed); haploid-diploid forms 4;
iploid-triploid forms 1; diploid-triploid-tetra-
loid forms 1; and triploids 1.

Maturation and autoregulation show a diversity
f conditions. No autoregulation can have occurred
Parmenter's haploid tadpoles and normal
duction must have occurred; there is cytological
vidence for this in the lamprey's egg (Montalenti[15])
nd in certain eggs of the echiurid *Urechis uni-
nctus* (Hiraiwa and Kawamura[6]). These new
ases can, therefore, be grouped with the few
thers known in echinoderms and molluscs, and
re comparable to those few cases in Nature
emplifying 'rudimentary parthenogenesis'. The
iability, partial at least, of haploid animals is
lso illustrated by Parmenter's haploid tadpoles
nd by other previously known parthenogonic
rvæ.

Autoregulation in natural parthenogenesis may
e designated "post-maturational", in which
iploidy is *regained* during ontogeny, and "matura-
onal", in which diploidy is *retained* consequent
pon chromosome behaviour that prevents the egg from becoming haploid. Now in the great majority of cases of natural obligatory parthenogenesis, diploidy is retained because the reduction division is suppressed, the single division occurring being equational, and it is a curious fact that, as yet, no like case is known in experimental parthenogenesis. On the other hand, Parmenter's experimental haploid-diploid tadpoles provide the unique example of autoregulation being delayed until the larval stage. All the other methods of natural autoregulation now find their parallel in the cases of experimental parthenogenesis, thanks in part to recent research. For example, the silk-moth egg in Russia provides the sole case in experimental parthenogenesis in which autoregulation occurs late in segmentation—in the blastoderm (Frolowa[16]); the silk-moth egg in Japan (Sato[5]), as well as a minority of Russian eggs (Frolowa[16]) and some of Parmenter's frog eggs, provide new cases of autoregulation occurring at about the time of the first segmentation division; others of Parmenter's frog eggs probably add another case illustrating autoregulation due to fusion of polar body and egg pronucleus; some eggs of *Urechis unicinctus* probably illustrate autoregulation by non-release of the haploid set of chromosomes normally extruded in the second polar body (Hiraiwa and Kawamura[6]); in *U. caupo* certain eggs possibly omit both maturation divisions (Tyler[7]), lending supporting evidence to Doncaster's[17] old interpretation regarding parthenogenetic gall-fly eggs. Some of these cases also illustrate the polymorphism of autoregulation in one and the same species even when the same experimental procedure is seemingly followed, for example, the eggs of frog, silk-moth and *Urechis unicinctus*, the last example manifesting types of autoregulatory behaviour additional to those cited above. Such polymorphism, however, may be due to undetected differences in the eggs. Of autoregulation in rabbit eggs cultured *in vitro* little is known, though Pincus[11] has observed fusion nuclei and indications that diploid cleavage nuclei occur.

The problems of segmentation and cell division receive fresh light from Harvey's parthenogenetic merogones of sea-urchin eggs. These develop asters and divide in a fairly orderly manner, and division is independent of such cell inclusions as yolk pigment and mitochondria and also of the presence of the nucleus—though not necessarily of nuclear secretions. Again, cleavage is independent of spindle and asters but dependent on the physical and chemical state of the protoplasm and its surface layer. Nor is the orderly succession of cleavage essential, for the cytoplasm may break up irregularly but still give a blastula. Cleavage, budding and fragmentation are therefore different expressions of the state of the cytoplasm or of the cell surface or of both. The maternal cytoplasm seemingly has potentialities for determining at least the early stages of development, a matter that lies at the root of the problem of genetical inheritance, for it raises questions regarding the functions and relations of cytoplasm and nucleus. To what may these potentialities be traced? Normally the cytoplasm receives nuclear material when the germinal vesicle breaks down, but the role of such material in maturation and segmentation is not known; nor is there certainty that the cytoplasm receives secretions from the intact germinal vesicle. Nevertheless it would be unwise to exclude the latter possibility occurring prior to the experimental removal of the vesicle from the egg fractions. Another possibility is that the chromatin of the previous generation influences the maternal cytoplasm. Of these matters Harvey is well aware.

Regarding experimental activation, the work of R. S. Lillie, Just, Runnström[18] and others with sea-urchin eggs indicates that its initiation is due to the release and interaction of substances originally separated in the egg cortex, with the consequent formation of an acid which may be a fundamental activator.

The physiological bases of experimental parthenogenesis have been discussed in masterly fashion by Dalcq[19] and he cites the serious limitations in our knowledge. The types studied hav been mostly aquatic and the facts gleaned fror them are of limited application to the majority c parthenogenetic animals, which are terrestria Cytological knowledge is really patchy and incomplete. No common activating principle ha been found in the many agents used, nor has th nature of experimental activation been elucidatec How far the mechanisms of experimental and c natural parthenogenesis and of fertilization ar identical is unknown, while as for the origin(s) c natural parthenogenesis, experimental method have not as yet revealed them.

OBITUARIES

Mr. C. J. Bond, C.M.G.

BY the death of Mr. C. J. Bond, Leicester has lost one of her most distinguished and also most beloved citizens. Few lives can have been more completely devoted to the service of mankind. He was a 'philanthropist' in the literal sense of the word.

Bond's skill as an operating surgeon, combined with his kindly and considerate manner towards his patients, had brought him one of the largest surgical practices in the Midlands, but he retired from private practice at a comparatively early age (in 1912) in order to have more time for purely scientific and social work. He was specially interested in biology and genetics, and he carried out numerous interesting experiments, extending over many years, in the breeding of poultry and pigeons. Another special interest was eugenics, and he delivered the Galton Memorial Lecture, under the auspices of the Eugenics Society, in 1928.

When the War broke out in 1914, Bond offered his services to the War Office and became consulting surgeon to the Northern Command with the rank of Hon. Colonel, A.M.S. As the representative of the Medical Research Council, of which body he was an active member for many years, he served on the Inter-Allied Commission on the Treatment of Wa Wounds, held in Paris during 1916–18. He wa twice mentioned in dispatches and was awarded th C.M.G. in 1917.

Possessed of exceptional ability and a seemingl tireless capacity for work, C. J. Bond readily gav his support to causes and movements which h believed would benefit his fellow-men. In this brie notice it is quite impossible to enumerate all hi many activities and interests, though reference shoul be made to his work for the Leicester Royal Infirmar of which he was consulting surgeon, member of th Board of Governors and vice-president; also to hi work for University College, Leicester, which h helped to start and of which he was a member of th Board of Governors; and for the Leicester Literar and Philosophical Society, of which he was twic president. Nationally, he served on the Departmental Commission on the Cause and Prevention o Blindness; on the Industrial Fatigue Researc Board (of which he was deputy chairman); Lor Trevethin's Committee on the Prevention of Venerea Disease; the Advisory Council of the Nationa Health Insurance Committee, etc. He was a lif member of the British Association.

Bond was a strong advocate of total abstinence and n active and generous supporter of the temperance movement, both locally and nationally.

He was the author of several books, for example, The Leucocyte in Health and Disease", which embodies the results of much painstaking original esearch work; "Essays and Addresses of a Surgeon", and Chapter v in "Health and Healing in the Great State", edited by H. G. Wells. He also made numerous ontributions to current medical and scientific iterature.

During the later years of his life, one of Bond's chief nterests was the movement for voluntary euthanasia. He helped to found the Voluntary Euthanasia egalisation Society, and he was chairman of the xecutive committee for the five years since the Society was started. Undoubtedly, the great prestige attaching to his name has greatly helped the movement, and he had the satisfaction before he died of eeing it steadily growing and apparently firmly established.

To those who knew C. J. Bond intimately—as it was my privilege to do for more than thirty years—e will be chiefly remembered, not so much on account of all the good work he accomplished during his long and active life, as on account of what he was. He was a man of absolute integrity, scrupulously concientious in everything he did or said, and modest of character, almost to a fault. It is impossible to think of him as ever being guilty of an unkind, elfish or unworthy action.

He leaves a widow, a son who is in the medical rofession, and a married daughter.

C. Killick Millard.

Prof. C. G. Santesson

Prof. Carl Gustaf Santesson, the eminent Swedish pharmacologist who died on July 26, was born in Stockholm on July 5, 1862, the son of the professor of surgery at the Karolinska Institutet. He received his medical education at Uppsala, Stockholm, and Lund, and qualified at Stockholm in 1890. During the next two years he studied pharmacology under Schmiedeberg at Strassburg and Boehm at Leipzig. On his return to Sweden he became lecturer in pharmacology at Uppsala, and in 1895 was appointed extraordinary professor in this subject at the Karolinska Institutet at Stockholm, becoming full professor in 1908. He retired in 1927.

In addition to numerous contributions to periodical literature on pharmacology and toxicology, Santesson was the author of a work on general pharmacology (1919). From 1901 until 1916 he was editor of the *Nordisk Medicinskt Arkiv* and from 1924 until his death of the *Skandinavisches Archiv für Physiologie*. The high reputation which he enjoyed at home and abroad is shown by his being a member of the Academies of Sciences of Uppsala, Stockholm, and Halle, the Finnish Medical Society and the German Pharmacological Society. An address on his life and work was delivered at a meeting of the Swedish Medical Society by Prof. G. Liljestrand, his successor in the chair of pharmacology, and published with his portrait in the *Nordisk Medicin* of October 14, and the issue of *Acta Medica Scandinavica* of October 17 contained the address delivered by Santesson two months before his death on the occasion of the publication of the hundredth volume of the journal.

J. D. Rolleston.

NEWS AND VIEWS

Anthropological Investigation in Mexico

On p. 1033 of this issue extracts are given from an account of some remarkable magico-religious observances recorded by Dr. Robert Gessain in the istrict surrounding Huehuetla, a village in the State f Hidalgo, Mexico, in which in certain respects the se of paper figurines, or *munecos*, recalls practices of Old World witches and the employment of waxen mages against their victims. The expedition, of which Dr. and Mme. Gessain were the personnel, was the fifth of a series sent out by an organization for which Dr. P. Rivet of Paris is mainly responsible. This organization, known as the "École française de Mexico", sends out each year a research worker to carry on investigations in that country. In view of Dr. Gessain's qualifications as medical man and anthropologist, in which capacity he had already worked in Greenland, the objective of the expedition was mainly to record observations in physical anthropology, including racial pathology, combined with nguistic and ethnographic inquiry as a subsidiary id in gaining the confidence of the people. Equipment for testing blood groups and making psychophysiological observations was also carried. Unfortunately much delay in reaching the base of operations was caused by difficulties in getting the scientific equipment into the country; and after a few weeks work only, both members of the expedition were taken seriously ill and had eventually to return to France. This happened at a peculiarly inopportune moment, as they had just made a beginning in breaking down the hostility and suspicion with which their early inquiries had been received. Notwithstanding this unfavourable attitude of the inhabitants, a number of interesting anthropographic and demographic observations have been made—the congenital or 'Mongolian' patch was found on all infants—and, in addition to the cultural evidence noted above, songs, technological films and a large number of anthropological and ethnographical photographs have been secured.

Oil and its Uses

The Petroleum Films Bureau (15, Hay Hill, Berkeley Street, London, W.1) now has a library of fifteen films about oil which may be borrowed free of charge by schools, technical colleges, scientific societies and other educational organizations. Both 35 mm. and 16 mm. sound and silent films are available. Synopses of these films giving an indication of the main themes dealt with are to be found in a catalogue recently issued by the Bureau. The films fall into three main sections, dealing with the varied aspects of oil production and drilling, some of the uses to which oil is put, and its particular adaptation to the requirements of the modern petrol engine, respectively. In the production and drilling section, there is one more or less general film giving an indication of how oilfields are discovered and wells drilled, which countries produce oil and how it is transported in tankers across the seas. This is followed by others having a more local bias. The work of James Young on the production of oil from shale and the subsequent establishment of the Scottish shale industry is only one of several themes which lend themselves admirably to pictorial development. Illustrations of the uses of oil are as diversified as they are manifold. They embrace fishing for swordfish, re-fuelling an Imperial Airways liner at Kisumu and spraying trees to destroy insects, to cite only a few examples. The films depicting first principles of internal combustion and compression ignition engines and the theory and practice of their lubrication are of necessity less spectacular in their conception. Nevertheless the diagrams and models will prove of great assistance to those seeking lucid explanations of technical details.

Antiquity

IN the December issue of *Antiquity*, the editor discusses in the frankest terms the future and the policy of that publication in relation to present conditions in international relations and world affairs. After the most careful survey of all possibilities and probabilities, it has been decided "to take courage, and at any rate plan for the year 1940". In arriving at this decision notwithstanding the difficulties which arise both from the almost complete cessation of all archæological activities on the outbreak of war, and from the absence on active service of many of its contributors and subscribers, the editor's decision has been determined largely by the view that the periodical for which he has been responsible both in and since its inception represents an essential contribution to learning and progress to which, so far as is humanly possible, there should be no interruption. In this opinion he is fortified by expressions of opinion from his supporters, of whom one writes that it is "of paramount importance that all *foci* of Culture and Learning should be kept alive" during the present troubles. While endorsing in the strongest terms this formula of one, at least, of the functions of publications of the class to which *Antiquity* belongs, we would also second the more readily the editor's appeal for continuance of that support from the public which has helped him to win for this publication the position which it holds in cultural studies to-day.

An Early Gas Mask

ATTENTION is directed in the *Journal of the Roy* *Society of Arts* (Nov. 3, p. 1239) to a description a mask which appeared in vol. 43 of the Society' *Transactions* (1825). It was designed by Joh Roberts, of St. Helens, Lancashire, "to enabl persons to breathe in thick smoke or in air loade with suffocating vapours", and was effective again smoke and also against a gas such as sulphurou acid. It consisted of a leather hood with two aperture filled with glass or mica to see through. The hoo descended to the bottom of the neck, was well wadde at the bottom, so as to be rendered airtight, or nearl so, when secured by the straps attached. From th nose a flexible leather pipe is attached, terminatin at the bottom in a trumpet-shaped piece of japanne tinplate, the open end of which is plugged with moist sponge kept in place by a piece of coarse clot Breathing is carried on through the tube, and an particles in the air or vapours or gases in any considerable degree absorbable by water are remove by the cloth filter and the moist sponge. An illustration shows a very workman-like piece of apparatu Details are given of various tests that were mad with it.

Alcoholism and Suicide

DR. MERRILL MOORE (*New England J. Med.*, 22 691; 1939) discusses the relation between alcoh and suicide in a paper based on the study of 14 alcoholic patients, admitted to the Boston Cit Hospital during the period 1915–38, who ha attempted suicide, out of a total of 1,195 admitte during the same period after attempting suicide 98 were men and 45 women. The great majorit were between the ages of thirty and forty. Condition of occupational, marital or economic maladjustmen were present in all. By far the greatest numbe were unemployed or of unknown employment, an few skilled workers were included. As regard motivation the reasons offered for the attempte suicide were occupational maladjustment, domesti friction, depression and anxiety. Poison by mout especially iodine, the ineffectiveness of which wa probably not realized, was the most popular metho of suicidal attempt. Inhalation of illuminating ga came next, while less frequent methods were slashing jumping from high places, hanging, immersion an firearms. 136 (95 per cent) were unsuccessful in thei attempt and only 7 (5 per cent) died after admissio to hospital, as compared with 11 per cent of th total number of suicidal patients admitted. Dr Moore attributes the large number of failures i suicidal attempts among the alcoholic patients partl to the ingestion of non-poisonous substances or sublethal doses, and partly to the tendency of th alcohol to render the method of suicidal attempt les efficient.

Social and Technical Aspects of Housing

THE methods employed in Belgium, the Unite Kingdom, Denmark, Finland, France, the Netherlands, Norway and Sweden for improving urban an rural housing conditions, and in the United States of America and Canada for urban housing, are reviewed n a study entitled "Urban and Rural Housing" conducted by M. B. Helger, of the Swedish Social Board, which has been published by the Economic Intelligence Service of the League of Nations (Geneva: League of Nations. London: George Allen and Unwin, Ltd. 3s. 6d.). The study has special reference to the cost involved and the results obtained, mainly n the housing problems raised after the War of 914–18, and the attempts at solving those problems up to the outbreak of hostilities in 1939. Separate hapters are devoted to each country, and figures are iven showing the need for additional accommodation, he lack of modern conveniences in existing dwellings, nd the number of existing dwellings which should be repaired, or demolished as unfit for further use. General aspects of the housing problem are discussed n an introductory chapter in which the two aspects—ocial and technical—of the problem are distinguished.

IN regard to the social aspects, the causes of fluctuation in building activity and their bearing on he periodic shortage of houses are examined. The echnical aspects are concerned with the quality of housing and are better treated separately because the ideas of public authorities as to minimum standards appear to make it impossible to solve the housing problem merely by the operation of supply and demand. This is partly because the income of many families is inadequate to enable them to obtain housing with the minimum conditions of health and comfort, and partly because many families fail to appreciate the importance of these conditions and make no effort to obtain suitable housing even when they can afford to pay the rent for it.

Economizing on House Fuel

According to *Science Abstracts* of November 4, E. S. Draper, director of the regional planning studies, reported at a meeting of the Committee on the Hygiene of Housing of the American Public Health Association, that by using adequate insulation against heat loss when building a small house, the cost of the fuel required can be reduced by nearly one half. A simple heater suitable for the central heating of small houses was developed after tests at the Gilbertsville Dam construction community and is now being placed in the open market. The insulation studies were carried out in two identical four-roomed houses in the Niwassee Dam construction community. The installation of electrical heaters made it possible to record with great accuracy the heat loss in the two houses. One of them was insulated throughout by wool bats in the walls and over the ceiling and an insulation board under the floor joists. Both houses had both doors weather-stripped. Both families obeyed the same schedule of window-opening in bedrooms at night, windows closed by day, and the heaters were turned on and off at the same times. The reduction in the total heat loss in the insulated house was 44·75 per cent. The cost of the insulation, including labour and materials, was about £40. The simple heater described by Mr. Draper was designed to effect a reduction in the capital cost of central warm air heating over that of installing the warm air furnaces available in the market. The object was to have a primary heat source (without provision for air filtering or humidification) placed in an exceptionally small first floor heating chamber centrally located, so that it might give service to all rooms of a small house without the usual extensive system and basement.

Accessibility of University Theses

"The Accessibility of British University Thesis Literature", a pamphlet prepared for the Nottingham meeting of librarians last September by Colonel Luxmoore Newcombe, principal executive officer of the National Central Library, is a full and careful survey. A thesis usually contains original matter which may be important for the advancement of the subject, and the range of special studies has been enlarged of late. It should be easily consulted, if only that the work may not be duplicated by some other specialist. This accessibility, the writer shows, is far from being satisfactorily arranged at present. He gives a list of all the theses for degrees at British universities, and the conditions under which they can be consulted. He includes also the collections of foreign theses available. Oxford received between 1885 and 1938 about 263,000 of these. Great Britain has no great guides to her published and unpublished theses such as exist in Germany, France and the United States.

THE French issue annually a volume containing on an average 2,150 entries, well indexed. The American catalogue of "Doctoral Dissertations" during 1937–38 includes 2,768 items, but here the degree sought is so common among teachers that good subjects are getting rare, and descriptive rather than original stuff finds a place. The library of the University of Aberdeen has no printed list after 1937. Edinburgh has published an annual list since 1931, but it cannot be purchased. In London an annual list of titles is published and a cumulative catalogue is to be made out of it every five years. Medieval studies and history are fortunate in special catalogues. Only six universities have both an author and a subject index. A national guide to all British theses should be made, and its natural place would be the Central Library. It should be possible for friends of research such as the Carnegie Corporation to back the scheme with adequate funds. Colonel Newcombe also suggests that the Library might have a copy of every foreign thesis on loan. The photostat seems a suitable means of increasing the supply of duplicates at the various universities.

Astronomy in Ancient Egypt

THE traditional view that the knowledge of astronomy of the Greece of classical times had been derived from Egypt, a view to which the writings of the Greeks themselves lent support, has lost favour with increased acquaintance with the achievement of the peoples of Mesopotamia in this branch of science, and of the indebtedness of Greek thought to Babylonian and Assyrian conceptions of the nature and movements of the heavenly bodies. At the same time, research on the astronomical knowledge of the ancient Egyptians has shown that its basis of exact and scientific observation has, if anything, been overrated. At the recent autumn meeting of the National Academy of Sciences, held at Brown University, Providence, R.I., on October 23–25, Dr. O. Neugebauer, in a communication on "The Egyptian Picture of the Sky" (*Science*, 90, 410; Nov. 3, 1939), pointed out that while Egyptian and Babylonian astronomy are usually quoted as equivalent foundations of Greek, and, therefore, medieval and modern astronomy, really very little is known about Egyptian astronomy. Investigation of Demotic texts, however, has now shown that Egyptian methods of treating the movements of the moon and planets were only very approximate, and without any consideration of details. This picture, Dr. Neugebauer stated, has now been completed by a Demotic text recently purchased by the Egyptological Institute in Copenhagen, which shows how the aspect of the sky and the setting and rising of the stars was connected with the religious myths. The close connexion of religion, especially so far as the underworld is concerned, with the changing aspect of the sky during the year indicates that the main interest of Egyptian astronomy was not a mathematically detailed description of very complex effects, but merely a rough scheme, just good enough to reflect the main traces of the observed facts.

Submarine Valleys

DURING the last nine years, the United States Coast and Geodetic Survey has made an intensive acoustic survey of the Atlantic continental shelf and slope of the United States. The surveys are now so far advanced that the surface topography can be studied in detail. Charts of most of the slope have been published by the Geological Society of America (Special Paper No. 7; 1939). The *Geographical Review* of October 1939 publishes "Atlantic Submarine Valleys" by Mr. R. A. Smith, with a chart on a scale of 1 : 1,000,000 of the shelf and slope, and adjacent land, between New England and Albemarle Sound. Even on this reduced scale many striking features are shown. The flatness of the shelf is so remarkable that only by the use of a five-fathom contour interval can any noticeable relief be shown. The slope, on the other hand, shows a topography so irregular and broken that a 100-fathom contour interval has to be employed for the sake of lucidity. While the shelf, for a distance of 60–125 miles seaward, shows beach forms, the outcome of marine erosion, or modified river forms, the continental slope is deeply dissected and shows forms characteristic of subaerial erosion. In many places the complexity of relief is much greater than that found in the Appalachian Mountains and is more comparable, according to Mr. Smith, with that of the western mountains of North America.

Lancashire and Cheshire Fauna

THE twenty-fifth annual report of the Lancashi and Cheshire Fauna Committee adds a large numbe of insects to the dual county lists and also to th British area and some species new to scienc Among Coleoptera, *Philonthus jurgans* Tott. was di covered new to science from a specimen obtained a Ashton-under-Lyme in 1935, since when it has bee found widespread throughout the British Isles, als occurring in Cheshire at Tarporley and Arden. *Aph davidsoniella* Theob., a species that has been separate from *A. rumicis* L., has been obtained on dock a Preston and Stalybridge. The fly *Bairamlia nidicol* Ferriere is described as new from material obtaine from flies breeding in birds' nests at Mobberley Cheshire. Six new moths are added to the dua counties' lists and one new to Lancashire. The bird mammal and Lepidoptera notes are largely of loca interest, but some of the more general items includ the breeding of the death's head moth from larvæ a Raby, Cheshire, a 1927 specimen of the rare migran Camberwell Beauty at Alderley Edge, Cheshire numerous foreign insects collected from importe fruit and other goods, the beetle *Cryptophagu acutangulus* Gyll feeding abundantly on the moul on damp plaster in almost all the new houses in th district, increasing numbers of red squirrels in th Ribble valley and in west Cheshire, detailed report of the surveys on reed-warblers, tufted duck an turtle-dove surveyed for the British Trust fo Ornithology, Lapland bunting at Ainsdale, where th little tern is nesting again, the spotted crake nestin in Cheshire, the bittern at Rostherne, the quail nea Nantwich and increasing numbers of reports abou many wading birds and duck formerly considered rar in the districts but which are obviously much mor frequently seen now. The committee, of which Prof J. H. Orton is chairman, has a membership of 28 and commences the year with a surplus of £146.

Merseyside Naturalists' President

THE annual meeting of the Merseyside Naturalists Association (the Merseyside Branch of the Britis Empire Naturalists' Association), held at Liverpoo Museum on December 3, elected Mr. R. K. Perry keeper of vertebrates at the Museum, president fo 1940, Dr. J. C. P. Miller, lecturer in applied mathematics in the University of Liverpool, as chairman, and Mr. Eric Hardy as honorary secretary. Formed last winter, the Society faces the War with a surplu in its ordinary and its sanctuary accounts, and wil shortly issue a portfolio of its faunal and floral work during the past year.

Horticulture of the Lily

THE eighth number of the Royal Horticultural Society's Lily Year-book (from the Society's Office, Vincent Square, Westminster, S.W.1, 5*s*. paper, 6*s*. cloth), makes a very effective attempt to keep pace with the multitudinous variations of these plants. Mr. A. Simmonds lists the names and origins of 114 hybrid lilies, and there are papers which arify the taxonomic positions of *Lilium bulbiferum* d its varieties, by Dr. Fred Stoker, *L. myriophyllum*, y Mr. A. D. Cotton, and *L. pardalinum* and its allies, y Dr. Vollmer. A happy personal note is struck by r. A. D. Cotton, in a biography of the late Dr. . H. Wilson, a vigorous botanical explorer who ntributed greatly to liliaceous garden beauty. apt. F. Kingdon Ward describes a new lily which e discovered in the Assam Himalayas, and Mr. . Ogilvie-Grant has collected several new fritillaries Greece. Other papers deal with the cultivation and orticultural grouping of the lilies which are now ell-tried favourites of our gardens. Scientific work pon lily matters does not appear to have been great amount. Dr. M. A. H. Tincker describes the rates f growth of roots in several species, and there is an ccount of a discussion on propagation. The net sult, however, is to show the need for more accurate ientific knowledge of all phases of lily horticulture—e relation of lilies to soil conditions, to nutrition in eneral, to pests and diseases. There are, indeed, fficient unanswered questions in the book to employ lily research station for a considerable period.

lant Growth-Substances

A RECENT report in the *Kew Bulletin* describes experiments conducted in co-operation with the garden aff but designed by Dr. C. R. Metcalfe and Dr. W. G. empleman to test the influence of synthetic growth-ubstances upon the rooting of cuttings of many lants ("Experiments with Plant Growth-Substances r the Rooting of Cuttings". By C. R. Metcalfe nd W. G. Templeman. *Bull. Misc. Information*, o. 8; 1939). Their results show that some 45 per ent of the species they selected have responded avourably to one or other of the treatments, which ncluded the use of solutions of indolylacetic acid, dolylbutyric acid, and α-naphthylacetic acid, at ifferent concentrations. The list of plants is a horoughly representative one including many well nown to practical propagators to be exceedingly ifficult to root from cuttings. Their successes include ome seventeen plants already listed by the Plant ormone Committee as difficult to propagate in this ay, but their results also show that other difficult lants have failed to respond to the treatments. The abular presentation of the data affords ready reference, and many nurserymen and gardeners generally ill consult their list, which, however, contains records f failures with a few species which have been successully propagated elsewhere at perhaps other seasons f the year. It is hoped that this work will be extended to include tests of these substances applied n powder form.

lant Disease Nomenclature

THE "List of Common Names of British Plant Diseases" compiled by a sub-committee of the British Mycological Society's plant pathology committee as been accepted by the principal societies and nstitutes in Great Britain which need to use such ames. A certain number of emendations to the econd edition are published in the Society's *Transactions* (23, Pt. 3; October 1939). No major correction appears to be necessary; the changes are such as give increased exactitude about the authorities for the names adopted, or which remove doubts previously felt about the nature of some diseases. Reasons and references are given for the more significant changes, and any mycologist interested further in this standard nomenclature may obtain additional information from Dr. G. C. Ainsworth, secretary of the Plant Pathology Committee, Imperial Mycological Institute, Kew, Surrey.

Demography of Dublin

IN the recently published report on the State of Public Health of Dublin for the year 1938 the Medical Officer of Health, Dr. Matthew Russell, states that the estimated population of the city was 477,000, the density of the population being 25·4 per acre, compared with 40·4 in 1929. The birth-rate, which was 24·4 per 1000 of the population, has shown a continuous decline since the beginning of the century, when the rate was 33 per 1000. The death-rate has shown a continuous but greater decline. In 1900 it was 30·5, whereas in 1938 it was 13·31, a drop of approximately 57 per cent. The infant mortality, while showing a considerable decline from that in the previous two years, was 98 per 1000 births, as compared with 106 in 1937 and 115 in 1936, is higher than the average—97—for the previous ten years. In 1934 the figure was as low as 74. The maternal mortality in childbirth showed a rate of 2·5 per 1000 births; the average rate for the previous ten years had been 3·07.

Earthquakes Registered at Kew

DURING November 1939 eleven earthquakes were registered on the seismograms at Kew Observatory, this number being probably fewer than the average. Nine of these are reported to have been small or confused by microseisms, and the other two both occurred on November 21. The first was received at 8h. 55m. 8s. G.M.T. with the *P* and *S* waves of small amplitude followed by large amplitude surface waves, and is stated to have been destructive in north-east Anatolia. The second was registered at 11h. 10m. 30s. G.M.T. and has been estimated to have occurred about 85 degrees distant in a direction north-east of Kew, with a deep focus, approximately 175–200 km. below the earth's surface.

Earthquake in New England

ON November 15 at about 3h. G.M.T. an earthquake was registered on the seismograms at the observatories of Weston, Georgetown, Ottawa, Pittsburgh, Fordham, Williamstown and Philadelphia. The United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the probable epicentre of this shock to have been near latitude 39° 45′ N., longitude 75° 18′ W., and that it had an origin time 2h. 53m. 48s. G.M.T. with a depth of focus near 25 km. below the earth's surface. Large earthquakes are very rare in these regions, though small shocks and tremors have occurred very occasionally in the past. That the present shock released only a very small amount of energy, thus being no exception, is shown by the facts that no damage has been reported in this well-populated region, and that the earthquake was not registered on the seismograms obtained at Kew.

American Association: Columbus Meeting

THE one hundred and fifth meeting of the American Association for the Advancement of Science is being held during December 27–January 2 at Columbus, Ohio. General sessions will be held on December 27, when Dr. Wesley C. Mitchell, of Columbia University, will deliver an address as retiring president of the Association on "The Public Relations of Science"; on December 28, when Dr. Kirtley F. Mather, of Harvard University, will deliver the annual address arranged jointly by the Association and the Society of Sigma Xi, taking as his subject "The Future of Man as an Inhabitant of the Earth"; on December 29, when Dr. Julian S. Huxley will deliver the first address in the United States under the arrangement between the American and British Associations to provide lecturers in alternate years, speaking on "Science, War and Reconstruction"; and on December 29, when Dean Marjorie Nicolson of Smith College, will deliver the annual address under the auspices of the United Chapters of Phi Beta Kappa, and will speak on "Science and Literature". Symposia have been arranged on "Isotopes", "Photosynthesis", "Speciation", "The Relation of Ecology to Human Welfare", "Defence Mechanisms in Plants and Animals", "The Internal Environment and Behaviour", "Effects of Science upon Human Beings"and "Blood, Heart and Circulation", among other topics.

Awards of the Geological Society

THE following awards of the Geological Society of London have recently been announced: the Wollaston Medal to Mr. Henry Woods, formerly University lecturer in palæontology in the University of Cambridge, in recognition of the value of his researches into the mineral structure of the earth, especially his studies of fossil Mollusca and Crustacea from the Cretaceous formations of Great Britain, Africa and New Zealand; the Murchison Medal to Prof. Arthur Holmes, professor of geology in the University of Durham, in recognition of the value of his petrological researches and of his stimulating studies concerning the composition and physical state of the earth's interior; the Lyell Medal to Prof. H. L. Hawkins, professor of geology in the University of Reading, for his eminence in palæontology, particularly in his studies of the Echinoidea, and for his researches in Eocene stratigraphy; the Wollaston Fund to Miss Dorothea M. A. Bate for her investigations of Pleistocene mammalian faunas in Palestine and the Mediterranean; the Murchison Fund to Archibald Gordon Macgregor, for his petrological researches into Scottish rocks and his work on the geology of Monserrat; a moiety of the Lyell Fund to Miss Dorothy Hill, for her researches on Palæozoic corals; anothe moiety of the Lyell Fund to Mr. L. H. Tonks, fo his work on the Carboniferous rocks of Lancashir and Northumberland.

Announcements

PROF. F. G. DONNAN, emeritus professor c chemistry in the University of London, has ha conferred on him the honorary degree of D.Sc. o the National University of Ireland.

DR. MARY EVELYN LAING MCBAIN, formerly o the University of Bristol and now of Stanfor University, California, has been elected nationa president of the American Women's Chemical Hono Society, Iota Sigma Pi, for the new triennium. Th Society comprises 2,500 women chemists. The nev secretary is Dr. I. Macy Hoobler, director of th Research Laboratory for the Children's Fund o Michigan.

A UNIVERSITY OF POLAND ABROAD was institute at a meeting held in the Polish Library, Paris, o December 1.

IT is reported in *The Times* that many of the sta and students of the University of Poznan are bein held under arrest as hostages. It is believed tha the intention is to repress Polish culture and scienc in this overwhelmingly Polish province.

THE University of Bern has awarded the firs international prize for researches on encephalitis t the Italian neurologist, Dr. Beppino Disertori.

THE January meeting of the Pathological Societ of Great Britain and Ireland will be held on Januar 12 in the Department of Pathology at Cambridg and not at Guy's Hospital.

THE London Scientific Film Society proposes t open its 1939–40 season early in the New Year. Th Society would be glad to hear from readers of NATUR of films on scientific subjects, either completed or i the process of production, which could be considered fo inclusion in the Society's programmes. Applications fo membership should be sent to the Secretary, L.S.F.S. 30 Bedford Row, London, W.C.1. The subscription for the season is 10*s*. or 15*s*., the higher rate entitling the subscriber to the better seats at the shows o the Society.

ERRATUM.—Referring to his communication entitled "A Peculiar Phenomenon Observed in Larval Populations of the Flour Beetle *Tribolium confusun* Duv.", Prof. John Stanley writes that the appearances of the various larval instars as indicated in Fig. 1 were given incorrectly in his original communication. They should read as follows: first insta 6·04 days, second instar 8·47, third instar 12·10, fourth instar 15·13, fifth instar 18·40, sixth insta 21·74.

LETTERS TO THE EDITORS

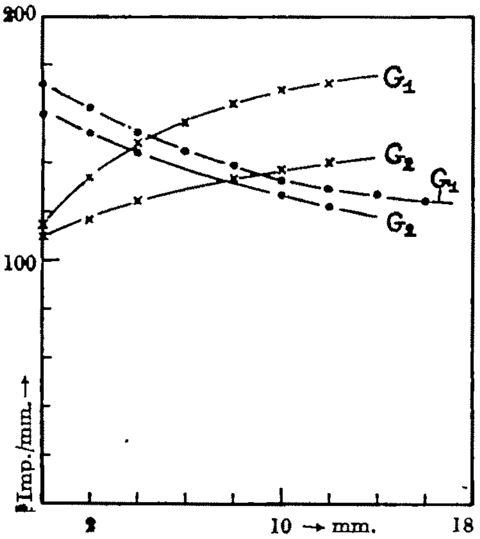
The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1051. CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Radioactive Gases Evolved in Uranium Fission

In this letter, a brief account is given of the preliminary results of an investigation of the radioactive gases evolved in the fission of uranium nuclei. This investigation was commenced this summer but was interrupted by the outbreak of the War. Even if the results so far obtained are not more complete than those obtained in the meantime by other investigators[1], it may still be of interest to describe the method employed, which follows somewhat different lines.



×, increase; •, decay

The radioactive gases evolved in the fission process were carried by a circulating stream of an inactive gas through two Geiger-Müller counters placed in succession. The time lag of the arrival of the gas in the two counters could be varied within wide limits by means of a system of capillary glass tubes of various bores placed in parallel and fitted with stopcocks. The magnitude of the lag was ascertained by separate experiments in which actinon or thoron was circulated. As a carrier gas, acetone vapour at a pressure of 10 mm. mercury was used because of its favourable properties for the working of the counters. The circulation was kept up by means of a Vollmer glass pump.

The uranium vessel, containing about 30 gm. of uranium oxide (U_3O_8), was surrounded by paraffin and provided with a well to allow introduction or removal of the neutron source, which consisted of about 30 mgm. of radon + beryllium. In the experiments, the counting rate of both counters was recorded for a period of time immediately following the commencement or cessation of irradiation. Typical results, using a time lag between the counters of 15 sec., are shown in the accompanying figure, from which it may be seen that the curves obtained for increase and for decay are almost complementary, and indicate several periods, of which some are of the order of a minute, while others are evidently much longer, giving rise to a residual activity almost constant within the time of the experiment.

The shorter periods were estimated from a decay curve obtained in a separate experiment, in which the flow of gas was stopped at the same time that the source was removed, and the records of the two counters at any subsequent time simply added. This gave two periods of about 30 sec. and 4 min., the ratio between the rates of production of the corresponding gases being estimated as 1·82. (Glasoe and Steigman (*loc. cit.*) find two gaseous products of uranium fission of periods 30 sec. and 5 min., of which the first transforms into a product of 3 min. period. It is possible that the period of 4 min. found in our experiments results from a combination of the periods 3 min. and 5 min.)

A test of these estimates was further obtained by calculating from them the values of the ratio between the counting rates of the two counters for steady flow with the various circulating periods obtained by inserting different capillary tubes in the circuit, and comparing the calculated values with the values measured 12 min. after the beginning of the irradiation. This interval of time is not quite sufficient for complete equilibrium to be established, but, on the other hand, it is sufficiently short compared to the periods of the long-lived transformation products to ensure that the values obtained do not depend on the formation of these products to any appreciable extent.

Assuming that the radioactive gas consists only of the two short-period components of decay constants λ_1, λ_2 produced at the rate of n_1, n_2 atoms per sec., the counting rate in any of the counters can readily be shown to be given by

$$G = n_1 e^{-\lambda_1\tau} \frac{1-e^{-\lambda_1\theta}}{1-e^{-\lambda_1 T}} + n_2 e^{-\lambda_2\tau} \frac{1-e^{-\lambda_2\theta}}{1-e^{-\lambda_2 T}},$$

where τ is the time taken by the circulating gas to travel from the uranium container to the counter in question, θ the time taken by the gas to flow through the counter, and T the period of the whole circulation process.

In the table are recorded the counting rates, G_1, G_2,

$\tau_2 - \tau_1$	G_1	G_2	$G_1 : G_2$	$(G_1 : G_2)$ calc.
15 sec.	108	63	1·72	1·31
50 sec.	94	45	2·09	2·01
2 min.	52	24	2·15	2·10
3 min.	42	21	2·00	2·01

for the two counters measured 12 min. after the beginning of the irradiation for four capillary tubes corresponding to values of the time lag $\tau_2 - \tau_1$ between the counters stated in the first column.

The agreement between the experimental and calculated values for the ratio $G_1 : G_2$ is seen to be very good except for the fastest circulation, for which the calculated value depends mostly on the shorter period and on the short time-lag, the determinations of which are the least precise.

Baade and Zwicky's Theory of Cosmic Rays, and the Helium Content of Beryls

PANETH and co-workers[1,2] have discussed the possibility that cosmic radiation may have produced the helium found in beryls by disintegration of beryllium nuclei, and they give experimental evidence that to do this the intensity would need to be at least sixty times greater. However, to reject cosmic radiation as a possible cause, on the experimental evidence, requires the assumption that, during the life-time of the beryls, the cosmic radiation has had its present intensity, whereas if the theory of Baade and Zwicky is true this is not so. These authors[3] have suggested that cosmic rays are produced at the flare-up of super-novæ. These, of which ten or so have been observed during recent years, rapidly reach a peak of brightness some 20,000 times that of the sun, lasting two or three days. During twenty-five days of maximum brightness they each emit, on the average, as much visible radiation as the sun does in 10^7 years, and after a life of a year or so they become faint stars[4]. They suggest that Tycho Brahe's nova of 1572 was a super-nova occurring in our Milky Way system. Zwicky estimates their frequency of occurrence as one per stellar system per 600 years[5]. They estimate that during its brief life a typical super-nova emits from 10^{52} to 10^{54} ergs, almost all in cosmic rays, and by averaging throughout the heavens they calculate a cosmic ray flux at the earth's surface of the same order of magnitude as the observed, namely, 3×10^{-3} ergs/cm.^{2} sec. However, they point out[3] that a super-nova occurring in the Milky Way 30,000 light years away would, for a short time, produce a cosmic ray flux at the earth some 10,000 times greater.

Evidently, if this theory is true, when considering the production of helium in beryls by cosmic rays, we must take not only the present cosmic ray flux into account, but also the average value due to one super-nova in the galaxy each 600 years. Let us assume that, in the past, super-novæ have occurred throughout the galaxy in proportion to the present density of visible stars. Then from Kapteyn's star distribution, as given by Jeans[6], I calculate the mean value of $1/D^2$, D being the distance from the earth to each super-nova, to be 4×10^{-8} (light years)$^{-2}$. An emission of 10^{54} ergs at the corresponding distance gives an energy at the earth's surface of 2×10^9 ergs/cm.^{2}, account being taken of the fact that a point on the earth can see only half the heavens. This equals the energy received in about 2×10^4 years at the present rate, so that, average over 600 years, the average rate of cosmic ray recep tion is about 35 times the present rate.

In view of the uncertainties of this type of calcula tion, it seems possible that the theory of Baade an Zwicky and the *experimental* data regarding th helium content of beryls are compatible. However there is a theoretical difficulty which is pointed ou by Fay, Glückauf, and Paneth[2]. The cross-sectio of the beryllium nucleus for disintegration by cosmi ray particles and quanta would need to be far greate than that predicted by the quantum theory eithe for photons or fast electrons, but as the quantum mechanics is inadequate to describe other qualitie of cosmic radiation, perhaps this theoretical difficult is not conclusive.

The suggestion that cosmic radiation has playe any appreciable part in the production of biologica effects, such as mutations, has also been discarde because of the small intensity. If Baade and Zwicky' theory is true, this conclusion also will need recon sideration.

"The Relativity of Time"

PROF. H. DINGLE has put forward[1] the view that, while it is correct to deduce the "Fitzgerald contraction" of moving bodies from the Restricted Principle of Relativity, it is incorrect to deduce the slowing down of moving clocks. His main ground is that the second statement is meaningless, because a clock is not a well-defined measuring instrument. If, for example, it takes the form of a stream of equal grains of sand falling regularly in an hour-glass, the time elapsed may be measured equally well by the *number* of fallen grains, N_1, or by their total *mass*, N_2, or by their total *volume*, N_3. Since mass and volume have different transformation laws for moving axes, Prof. Dingle infers that N_1, N_2, and N_3 also have different transformation laws, some showing the retardation and others not.

If this argument is intended to show a real difference between kinds of clocks, it must mean that if two hour-glass clocks are synchronized and moving together, and if one contains a counting apparatus and the other an apparatus for finding the mass of the fallen sand, then although at any instant they show the same reading for an observer relatively at rest, they show different readings for a moving observer. This is clearly not true, if the distance between the clocks is negligible: if the two dials look the same, at any given instant, to one observer, they look the same to all, no matter what mechanism is behind them. What appears to have been overlooked is that the sand and the measuring apparatus both form part of the clock, and therefore move together: the mass involved is the rest mass, and its effect on the transformation law is *nil*. To obtain Prof. Dingle's transformation law the mass of the moving sand would have to be measured by the stationary observer, an arrangement which can scarcely be called a "clock".

In any event, if it is equally legitimate to read a sand-clock by counting grains and by weighing them, must also be equally legitimate to read a measuring od by counting its divisions or weighing a piece of it, o that any difficulties on this score about clocks will e paralleled by difficulties about rods. The problems of a logical theory of measurement appear to be ymmetrical with respect to space and time.

M. H. A. NEWMAN.

St. John's College,
Cambridge. Nov. 27.

NATURE, 144, 888 (1939).

I CANNOT agree with Mr. Newman that an instrument which measures time in terms of the mass of allen sand is not a clock. If such an instrument is assed by a recognized observatory, I should be glad o know on what authority Mr. Newman would reject t. If it is accepted, then the mass must be measured, directly or indirectly, whenever it is used, whether moving or at rest. A consideration of what an observer would see on a dial is not sufficient to determine such a measurement, as perhaps the ollowing example will show most convincingly. Suppose we wish to find how mass varies with velocity. Insert a body in an apparatus which ndicates its mass by a pointer reading on a dial. Now recede from the apparatus with velocity, *v*. o long as the dial can be seen its reading will, learly, appear the same. Hence if Mr. Newman is right, mass is invariant. It is not "equally legitimate o read a measuring rod by counting its divisions or weighing a piece of it", because the standard of space measurement in physics is defined as the length, and not the weight, between two fixed marks.

I should add that I did not say that "it is correct to deduce the 'Fitzgerald contraction' of moving bodies from the Restricted Principle of Relativity". The Restricted Principle of Relativity is an expression of the Fitzgerald contraction.

Flame Method of Spectrochemical Analysis

UNDER the present troubled conditions there is no prospect of Dr. F. Majewsky's publishing in the near future his six months' work here ending August 1938. I therefore wish to place his main results on record.

His main work consisted in improving and adapting for routine use Ramage's flame method of spectrochemical analysis. Ramage[1,2] burnt a small quantity usually 50 mgm.) of powdered plant material rolled n filter paper in an oxy-coal-gas flame in front of a spectrograph. Reproducibility of results depended on the uniformity of feeding the roll into the flame. This was made difficult by the roll bursting into flame just outside the oxy-coal-gas flame.

The difficulty was overcome by raising the roll to a sufficiently high temperature to drive off inflammable gases and carbonize it before burning it in the oxy-coal-gas flame. This improvement alone resulted in increased reproducibility of results and increased sensitivity of the method.

We affected a further improvement by combining with the heat treatment immersion in ammonium chloride vapour to convert the minerals into their chlorides. This resulted in an increased sensitivity which varied from thirty-fold for calcium, the chloride of which is much more volatile than the carbonate, to nil for potassium, the chloride and carbonate of which are about equally volatile.

Dr. Majewsky was able to burn a roll treated in this way always in 75 seconds, whereas untreated ones were consumed in about 50 seconds, but the actual time varied by some seconds from roll to roll.

Quantitative results were obtained by comparing the unknown spectra with those given by rolls impregnated with known mixtures of salts. A statistical analysis of the results obtained with strawberry leaves showed that the means of two determinations each done in triplicate must differ by 12–18 per cent to have a twenty to one degree of significance. This degree of accuracy is sufficient for many horticultural purposes.

Differences between replicate determinations were much less for solutions than for leaf material, and the apparent amounts of most of the minerals showed parallel variation in the spectra of solutions but less so in those of leaf material. These results suggested that the comparatively small variation between replicates of determinations on solutions was due to faulty standardization of burning, and that the increased variation between replicate results on leaf material was due to lack of homogeneity of the leaf sample. These and other facts raise the hope of a further considerable increase in sensitivity and accuracy.

The comparatively simple and inexpensive method worked out by Majewsky was then used by S. G. Thompson for examining leaf samples sent to East Malling by me from South Africa, and proved adequate for a preliminary survey of the mineral status of fruit trees. The results obtained showed some remarkable agreements with horticultural performances and with diagnosis by plant injection.

As there is unfortunately no prospect of Majewsky's paper being published in the near future, it seems desirable to report briefly his contributions before their importance is masked by the superstructure which we hope to build on them.

Surnames and Blood-Groups

As is generally known, very large series of blood-groupings have been made in recent months in connexion with the emergency blood transfusion service. Among these depots, one has about 12,000 cases on record.

As the district is one of recent industrial development associated with immigration, it occurred to us to examine whether the blood-group frequencies are associated with surnames. A group of characteristically Welsh surnames was chosen centred on the eight types, Davis, Edwards, Harris, Jones, Lewis, Morgan, Phillips and Roberts, a selection for which we are indebted to Mr. B. S. Bramwell of the Society of Genealogists. This accounted for 5·2 per cent of our sample.

The percentages of the four blood-groups and the two sexes are shown in the accompanying table.

PERCENTAGES CONTRIBUTED BY THE SELECTED WELSH SURNAMES TO DIFFERENT GROUPS.

	O	*A*	*B*	*AB*
Women	5·4	4·3	5·7	3·8
Men	5 7	5·1	5·9	4·5

It may be observed that in each group the percentage of men is higher than that of women, as might be expected from recent immigration of a number of unmarried men. This difference is, however, not statistically significant. In both cases, however, the percentage is lower in group *A* than in *O*, and again lower in *AB* than in *B*. This difference is quite significant, and confirms the conjecture that recent population movements, even within Great Britain, can lead to significant association between surnames and blood-groups.

There are probably many other places in which empanelling for blood transfusion is now sufficiently active for local heterogeneity to be detected by the same method. Local surname frequencies may be obtained rapidly from telephone directories, and more thoroughly from marriage registrations, of which the Society of Genealogists has a large collection.

Human Origins and Taboo

IF we think of the evolution of man from some anthropoid stock as the evolution of mainly instinctive (innately conditioned) behaviour into mainly customary (socially conditioned) behaviour, we can both see the possibility of the formation of a larger group than the family one characteristic of extant anthropoids and can relate the said possibility to the facts of taboo—and totemism.

It is commonly and plausibly assumed that the reason why anthropoids do not form larger groups than family ones is the difficulty the larger group would have in finding sufficient food. This difficulty would not arise to the same degree in the case of anthropoids whose behaviour-habit was becoming less instinctive, more customary. The more variegated the dietary customs of family-groups of such a species became in course of ages, the more possible it would be for such groups to combine permanently together without undue strain on the food-resources of the larger group thus formed. It is a matter of pooling experience. When two heads began to be better than one, *Homo sapiens* was in sight.

Customary behaviour is initiated by individuals acting consciously in a novel manner, making a habit of novel and 'agreeable behaviour' and making a negative habit of novel and 'disagreeable behaviour'. In general, the agreeable behaviour *is* viable and the disagreeable *is* unviable. But accidents of conditioning occur in Nature as they occur, not as accidents, in the experimental psychologist's laboratory. A dog can be conditioned to regard anything whatever as 'taboo', so to speak; it is merely a matter of administering some unpleasantness concomitantly. Similarly, in a state of Nature negative customs *could* be formed by accidents of conditioning in regard to objects suitable for food, and it is almost a statistical necessity that our family-groups of anthropoids during the ages while, *as* family-groups, they were evolving their respective customary diets, should have formed one or more such negative customs. There would be nothing to distinguish these 'mistakenly' conditioned negative customs for their 'owners' from customs normally conditioned by di agreeable experience until *after* families were combined in larger groups. Even then we are still long way from the name and concept of 'taboo' an from totemistic theories of food-taboo practices an social organization, but all that follows easily enoug

This hypothesis is an application of my "Novu Organum" (Longmans, 1931), namely, the assumptio of 'nature as habit' in a sense of 'habit' quite th reverse, in relation to 'mind', of Hering's and Butler notion of 'habit'.

Metaplasia and Adenoma-like Changes in the Uter of Rats Injected with Sex Hormones

SQUAMOUS metaplasia in the uterine epithelium ca be considered as the first stage of pre-cancerou changes. In a previous publication[1], we have give the literature on the subject and have described ou own experiments, which showed that metaplasia i the uterine epithelium, produced by injections int the rats of œstrogenic hormones, can be decreased c prevented by the simultaneous administration (progesterone, the hormone of the corpus luteum.

In another paper[2], on the basis of a few exper ments only, we have suggested that male hormone when injected simultaneously with œstrogens, migh influence the metaplastic changes.

We have now completed a series of experiments o 105 normal or ovariectomized rats. The animals wer injected for 2–3½ months with œstradiol dipropionat or benzoate-butyrate (0·018–2 mgm. a week) alone or simultaneously with male hormones (androsteron 7·5 mgm., testosterone propionate 2·25–7·5 mgm and testosterone dipropionate 7·5 mgm. a week In one experiment progesterone (4·5 mgm. a week was given in addition to œstradiol dipropionate an testosterone propionate. The results obtained ca be summarized as follows:

(1) The percentage incidence of the metaplasti changes may be the same in the rats injected wit œstrogens as in those injected with both œstrogen and male hormones.

(2) With the doses used, however, adenoma-lik changes in the uterine glands and the most sever degree of squamous metaplasia of the uterin epithelium were found only in the latter group of rat

(3) The addition of progesterone considerabl decreased or in most cases prevented the metaplasti changes.

(4) The results obtained add weight to th suggestion that disturbances of the ratio of th male and female sex hormones, simultaneousl present in the organism of either sex, may be a important factor in the occurrence and developmen of some types of neoplastic growths.

ffect of Œstrogens on the Pouch of the Marsupial *Trichosurus vulpecula*

Trichosurus vulpecula, the common Australian ossum, has a well-developed pouch which shows arked reactions towards the administration of strogens. After the injection of small doses of strogen (200–1,000 I.U.), development of the pouch d mammary glands becomes evident, particularly in xually immature animals. Furthermore, hyper-asia of the pouch muscles is noted as well as the cretion of a pigment which is deposited within the uch and which stains the hairs a deep orange ithin the pouch as well as those around it. After e administration of one or several moderately large ses of œstrogen (1,000–10,000 I.U.), hyperplasia and pertrophy of the muscles of the pouch occur, and e pouch decreases in size. After the administration of single large dose of œstrogen (50,000–1,000,000 I.U.), e hypertrophy and hyperplasia of the pouch muscle come marked and it goes into a state of contraction hich is accompanied by an almost complete dis-pearance of the pre-experimental pouch.

If the injections of large doses of œstrogen are aintained, the contraction of the pouch remains rmanent, but the animal dies from the action of e hormone on the internal reproductive organs. his end result is similar in animals which possess nall or large pouches pre-experimentally; but it cessarily becomes more obvious in animals which d large pouches before injecting the œstrogen. his reaction indicates that the muscle of the pouch, hich is voluntary muscle, is contracted by œstrogen.

evere Mortality of *Mactra corallina cinerea* (Montagu) off the Lancashire Coast

I was informed by Mr. J. H. Duggan that enormous umbers of molluscs had been thrown up on the coast etween Southport and Hightown on October 28. hey then formed a continuous belt averaging six et in width and ten inches in depth at the crest, tending nine miles from Southport towards High-wn. The majority were, at this time, alive.

I visited the area on November 1 and found that e tides since October 28 had scattered the molluscs ver a zone averaging twenty-five yards in width. hey were arranged in drifts parallel with the high ater mark and usually five in number, the heaviest posit being in the most shoreward drift. In many laces this drift was five inches deep and five feet ide.

Most of the molluscs, at this time, were dead, but the deeper drifts the ones underneath were still live, having been protected from the wind and sun y the upper ones. The fact that no deposits were und in which all or most were alive suggests that one had been cast up since October 28.

Only one species of mollusc was present, namely, *actra corallina cinerea* (Montagu), and all were nall specimens, averaging 0·9 in. in length, and bviously the same year's spat.

It was found that one cubic foot of the drifts con-ined approximately 3,600 specimens of Mactra, so hat Mr. Duggan's figures imply a belt nine miles long, six feet wide and, say, seven inches average depth, from which a conservative estimate of the mortality of the Mactra can be obtained. This figure is in the order of 600 millions and, as Orton has stated[1], represents a tremendous loss in fish food.

Two previous records of great numbers of molluscs being cast on to this beach have been made: Chaster[2] recording *Cardium echinatum* being washed up in great numbers in January 1891, and Orton[1] recording great mortality of *Abra alba* and *Donax vittatus* in November 1929.

Orton suggested that the mortality was due to a certain wave action set up by a combination of the action of spring tides and a strong inshore wind, which washed out the organisms in the surface layer of the sea bed. In the present case, however, the mortality occurred at the time of the spring tides, but an offshore wind was prevailing.

It is interesting to note that on each of these three occasions a different species was cast up. This might be due to one of two alternatives: either the population of the sea bed off the shore has changed in the time between each of these events, or a different area of the sea bed has been affected by the tides on each occasion.

Chitin Content of the Mandible of the Snail (*Helix pomatia*)

The presence of chitin in the above-mentioned organ has been indicated so far by means of colour reactions only, probably owing to the lack of material. During the course of another investigation, we came into the possession of 650 mandibles (1 gm.), and an acetolytic breakdown experiment was carried out. After boiling with dilute alkali and hydrochloric acid, the remainder weighed 70 mgm., and yielded upon the application of Bergmann's method 8 mgm. of colourless needles which were identical with octa-acetyl chitobiose: m.p. 290°, nitrogen content 4·4 per cent. The experiment shows that the presence of chitin can be proved in even minute amounts of natural substances.

Potential Hosts of Potato Viruses in Garden and Field

In the spring and summer of 1938 one of us (R. N. S.) was working on potato leaf roll with the object of producing an attenuated strain of the virus. To this end, attempts were made to convey leaf roll not only to members of the Solanaceae but also to a wide range of unrelated genera. Two successes were secured by means of grafts, one with Matthiola, the other with a garden Campanula, both of which behaved as carriers.

Encouraged by these results we have explored, during 1939, the possibility of such infections occurring in plants grown as field crops. In particular, we attempted to infect cruciferous weeds and cultivated

Brassicæ both by means of graft and by the agency of the aphid *Myzus persicæ*. We succeeded in conveying leaf roll twice, once through a turnip and thence to a President potato, in both instances by graft; and again through a Brussels sprout and on to a President potato, both by means of the aphis *Myzus persicæ*. Neither hosts showed any symptoms, but the virus which was recovered on the Presidents produced a typical leaf roll in the first case and a poorly developed and ambiguous syndrome in the second.

We were from the start, however, confronted with an unexpected complication: in a large number of cases the virus carried over to the potato and thence to tobacco or *S. glutinosa* plants from infected Brassicæ or other foreign host was the *Y* virus (Sol. Virus 2, K.M.S.), and not leaf roll. Careful checking of all controls and examination of our potato leaf roll sources showed that it was these latter which were harbouring the *Y* virus, notwithstanding that they had been exhibiting acute leaf roll for nearly twenty years without a sign of the usual *Y* virus symptoms.

Our researches have proved that the *Y* virus can be carried by turnips, cabbages, kale and Brussels sprouts without symptoms, and that from them it can be conveyed to potatoes by graft or by means of *Myzus persicæ*, and thence to tobacco or *S. glutinosa*. In addition, we have shown that red clover, the garden pea and bindweed may be infected with the *Y* virus by means of *Myzus persicæ* without producing symptoms. The Brassicæ are frequently the overwintering hosts of *Myzus persicæ*: may it be that they and the well-nigh ineradicable bindweed may also act as reservoirs for these destructive potato viruses during the winter months?

A Bacterial Disease of Forsythia

A BACTERIAL disease has appeared in an East Anglian nursery on bushes of *Forsythia spectabilis* and *F. intermedia*. When, early in the year, the two-year-old branches are removed to the forcing house, the flower buds remain dormant or open imperfectly. Sometimes only a few twigs on a branch are affected; more often the branch as a whole remains dormant. Examination of the cut end of the shoot shows a stain in the wood, usually crescent-shaped, and varying in colour from scarlet to dark brown. At the time of cutting, the diseased branches cannot be distinguished superficially from healthy branches, but the stain in the wood betrays the presence of the disease. On any bush, healthy and diseased shoots arise from different stools. Excision of diseased branches (but not of the diseased stools) has been practised, but the bushes continue to die back, indicating that the disease can spread from the diseased to the healthy stools.

From stained wood a bacterium was readily isolated; this produced green fluorescence on beef-infusion agar and in Uschinsky's solution. Its reactions in culture media show it to be closely related to *Pseudomonas syringæ*. The Forsythia organism was inoculated into the wood of young Forsythia bushes growing in pots, and produced a dark stain in the wood; the following spring the flower buds opened normally. Inoculated int swelling flower buds, the organism caused a delay opening of about a week compared with wounde controls. When inoculated into young succulent lil and Forsythia shoots, blackened lesions appeared shortly afterwards the shoots died. *Ps. syringæ* w inoculated into the wood of Forsythia bushes b produced no stain in the wood and did not affe the opening of the flower buds. When *Ps. syring* was inoculated into young succulent shoots Forsythia, black lesions developed and shortly afte wards the shoots died and turned black.

It thus seems probable that the organism isolate from Forsythia belongs to the *Ps. syringæ* grou Wormald[1] records a disease of Forsythia, probabl caused by *Ps. syringæ*, the symptoms of which we elongated black lesions on the shoots and spots o the leaves.

Excretion of Thiamin and Biotin by the Roots o Higher Plants

THE fact that soil in the immediate vicinity plant roots supports a much higher microbial population than that existing outside the plant's zone influence has been recognized for many year Although it has been suggested that 'root excretion account for this effect, these hypothetical exudate have never been identified, nor has their mode action been satisfactorily explained. In studying th relation of plants to soil-borne diseases, it was considered desirable, therefore, to examine the possibilit that excretion of minute amounts of bacterial growt factors by the growing plant might be a fundament factor in determining the character of the rhizosphe microflora.

One hundred representative bacteria were isolate from each of the rhizospheres of Bison and Novelt flax, after three weeks' growth in uniform soil unde greenhouse conditions, and from the rhizospheres o two varieties of tobacco grown in the field. A simila number of control organisms was isolated in eac case from soil outside the root's zone of influenc Each of the isolates was inoculated into two medi one containing glucose, potassium nitrate an inorganic salts, and the other containing, in additio cysteine 50 mgm., *m*-inositol 100 mgm., thiami 100 γ, β-alanine 100 γ, nicotinic acid 100 γ, an biotin 0·5 γ, per litre. All growth-substances wer used in pure form except biotin, a concentrate o which was prepared by the procedure of Kögl an Tonnis[1] and shown to be approximately 0·5 per cen pure[2].

Results in every case showed that those organism dependent for their development on a supply o previously synthesized growth-factors were markedl more abundant in the rhizosphere than in contr soils[3], suggesting that the plant may excrete th necessary factors for their nutrition. In testing th growth-factors separately on twenty-five organism selected from flax and tobacco rhizospheres, fo which the more complex medium was essential, a were found to require either thiamin or biotin o both, but in no case did inositol, β-alanine, or nicotinic acid show any growth-promoting properties.

Although these findings indicate that the plant possibly exerts at least a part of its 'rhizosphere effect', through ability to excrete thiamin and biotin, more direct evidence to support this tentative assumption was desired. Seeds of Novelty and Bison flax were sterilized, and germinated in petri plates. After four days at 28° C. the seed-coats were carefully removed from the cotyledons and the seedlings planted in 8-in. test tubes containing 15 ml. sterile utrient solution. A circular disk of cheese-cloth supported by short lengths of glass tubing held the plant at the surface. Following one, two and three weeks of growth, the nutrient solutions from five tubes, containing one plant per tube, after being checked for sterility, were combined and concentrated n volume to 10 ml.

The plant excretions were assayed for thiamin by the growth response of *Staphylococcus aureus* in a medium containing all essentials except the substance to be determined[4]. The presence of thiamin was readily detectable by this method; the excretion from five Bison flax seedlings was 0·23 and 0·64 gammas, nd from five Novelty flax 0·24 and 0·64 gammas after one and two weeks of growth respectively. The appearance of inhibitory material in the plant excreions after two weeks interfered with this assay on older seedlings.

Biotin was assayed by the response of *Rhizobium rifolii* (Wisconsin Strain 205) according to the technique described by West and Wilson[2]. The amounts of this factor excreted in one, two and three weeks were in the neighbourhood of 0·06, 0·25 and 0·21 gammas, and 0·08, 0·20 and 0·20 gammas for five Bison and Novelty flax seedlings respectively. While it is recognized that the accuracy of these results depends on the validity of the assay methods concerned, it is believed that the specificity of these microbiological tests has been satisfactorily established for the strains employed[2,4,5,6,7].

From these observations it appears that the excretion of significant amounts of thiamin and biotin from young roots of higher plants occurs normally, even under sterile conditions, and accounts, at least in part, for certain quantitative and qualitative differences characteristic of the bacterial flora of the rhizosphere.

Points from Foregoing Letters

L. Wertenstein was investigating the radioactive gases evolved in the fission of uranium at the Mirosław Kernbaum Radiological Laboratory of the Warsaw Society of Sciences when Poland was invaded. Writing from Turczynek, near Warsaw, he describes some of the results he had obtained. The radioactive gases were carried through two Geiger-Müller counters placed in series and the time lag of arrival of the gases in the counters could be varied by a system of capillary tubes. Typical curves indicate bodies of period of the order of a minute, and others of much longer period, giving almost constant residual activity within the time of experiment.

J. Read points out that if Baade and Zwicky's theory of cosmic radiation is true, the experimental vidence regarding the helium content of beryls is ot incompatible with the assumption that this helium was produced by cosmic rays. The possibility f biological effects due to cosmic rays would also eed reconsideration.

M. H. A. Newman questions Prof. H. Dingle's view hat the current doctrine of the slowing down of moving clocks in relativity is incorrect. Prof. Dingle, n reply, maintains that the clocks described by him are legitimate, and that the uncorrected dial readings referred to by Mr. Newman are not relevant to the problem.

F. Majewsky and W. A. Roach have rendered Ramage's flame method of spectrochemical analysis more sensitive and the results more reproducible. The roll containing the sample is introduced into mmonium chloride vapour to drive off volatile gases nd convert the minerals into their chlorides before the roll is burnt in the oxy-coal-gas flame.

J. C. McKerrow suggests that some anthropoid became man as behaviour became more and more conditioned by custom. Confirmation of this hypothesis, itself based on the view of Nature which he has propounded in "Novius Organum", is found in the facts of taboo and totemism.

Since adenoma-like changes and the most severe degree of metaplasia appear in the uterus of rats only when male hormones are administered in addition to oestrogens, V. Korenchevsky and K. Hall conclude that disturbance of the ratio of the male and female sex hormones may be an important factor in the occurrence and development of some types of tumours.

Heavy mortality of *Mactra corallina cinerea* (Montagu) on the Lancashire coast is reported by G. E. Williams. Comparisons are made with two previously recorded mollusc mortalities on this part of the coast.

R. N. Salaman and W. R. S. Wortley have shown that the cultivated Brassicæ, as well as the garden pea, red clover and common bindweed, may be induced to behave as symptomless hosts of two destructive viruses which affect the potato crop. It is suggested that certain of these plants may serve as virus reservoirs as well as overwintering hosts for the aphid vector.

G. Metcalfe describes a disease of Forsythia, apparently caused by *Ps. syringæ*.

The excretion of thiamin and biotin from young roots of higher plants has been found by P. M. West to be of significance in explaining the occurrence of high numbers of bacteria requiring those growth substances, in the soil adjacent to the root surface.

RESEARCH ITEMS

Rock Art in North Africa

M. **Raymond Vaufrey** has now added to his previous reports on the results of his researches on the rock art sites of southern Oran and their bearing on the origin, affinities and chronology of the north African neolithic, further details of the sites, comparative studies, and full illustration (*Arch. de l'Instit. de Pal. Humaine*, Mém. 20; 1939). On four groups of sites, in the mountains of Figuig, Ksour, Géryville and Jebel Amour, the association of a stone industry with these rock-engravings of animal and human figures, an association previously undetected, made it possible to assign this art to a neolithic with Capsian traditions, which is shown to extend to northern Oran and beyond, linking up with the neolithic of the Sahara and a neolithic pluvial period, to which a date is assigned ranging from the middle of the sixth to the middle of the second millennium before our era. In order to test the application of this dating to the North African neolithic with Capsian tradition and the associated rock art of Oran, the comparison, obvious on both geographical and cultural grounds, is made with proto-historic and pre-dynastic Egypt. Here it is found that certain cultural elements in the North African neolithic are to be assigned to the various cultural stages or 'civilizations' now distinguished—Tasian, Badarian, Amratian, Gerzean—dating from at most 6000 B.C. to about 2000 B.C. But whereas these cultural elements or traits appear at various stages in Egypt according to the 'civilization' to which they belong, in North Africa they appear together—a fact which is explicable only on the ground that the North African is 'colonial' in character in relation to Egypt. A possible affinity of certain rock engravings showing a chariot with galloping horses fixes the latest dating at the opening of the Eighteenth Dynasty, 1580 B.C. As regards its racial character, the culture in Oran is linked with the race of Mechta el-Arbi, which has been shown to have Cro-Magnon affinities.

Tardenois Site in Western Scotland

Microlithic sites in Scotland have been discovered chiefly towards the east coast, while the well-known exception of Shewalton Moor, near Irvine, is probably to be assigned to well into the Bronze Age. A newly discovered site at Ballantrae, Ayrshire, described by the Rev. W. Edgar (*Trans. Glasgow Archæol. Soc.*, N.S., 9, 3; 1939) has so far yielded only the earlier types of microliths and may, therefore, be assigned to the Middle Tardenoisian. The site is situated on the 50-ft. beach extending from Laggan Burn to Downan Point over a distance of about a mile and a half, with an average breadth of about one quarter of a mile. Two streams intersect the area, which with the Laggan Burn supply an abundance of water. The area is fertile and mostly under the plough. Up to the present, only surface finds have been made, nor has the area been examined where not turned by the plough. So far no evidence of pit-dwellings or occupation floors, or traces of charcoal have been found, though concentrations of implements suggest the activities of craftsmen at localized centres, in two or three instances supporte by an abundance of cores. The implements collecte include blades in comparatively large number generally of the small battered-back type. Th triangular is not frequent, but some crescent-lik forms have been found; also micro-burins in number the majority of the usual type; scrapers in larg numbers and in different varieties; notched flak not uncommon; gravers, though rarely, two bein 'accommodation pieces'; and cores in abundanc mostly pyramidal.

Origin of the Grasping Movement in Man

Prof. Davenport Hooker, reporting on researc work towards which financial support has been give from the Penrose Fund of the American Philosophic Society (Year-Book, Amer. Phil. Soc., Philadelphi 1938), states that observations on the developmen of the grasping reflex in human fœtuses prove th independence of its two phases, finger closure an gripping, as they develop sequentially. Finge closure appears at about 11 weeks of menstrual ag as a quick, though only partial, flexion of the finger in which the thumb is not involved. Though th thumb may become feebly mobile so early as 12 week in response to tactile stimulation of the palm it play no part in the grasp by 25 weeks—the terminal ag of the present observations. Finger closure become progressively more complete. At and after 16 week tactile stimulation of the palm usually evokes com plete closure. Gripping has first been observed at abou the eighteenth week. It continues feeble for th remainder of the age-span studied. Further stud may modify the age-levels at which these charac teristic responses appear. Up to the present 4 individuals have been studied in a period of six years the age-span covering from 7 to 25 weeks. It is th second largest series ever studied and the only on documented by objective records, the fourteenth wee being exceptionally well covered. An atlas coverin fœtal activity from its initiation, about the eight week, through the 14 weeks stage has been prepared

Robin Redbreast Pigment in Fowls

Mary E. Rawles (*J. Gen.*, 38, 517–431; 1939 grafted small pieces of skin from the head of a 90–96 hour-old embryo robin on to the right wing bud of 73-hour-old White Leghorn. On hatching, the host showed areas of down coloured cinnamon brown o part or all of the right wing. In one case this wa later replaced by juvenile contour feathers of colour typical of the robin. After moulting, th feathers were host coloured. The barbules were o the structure of the White Leghorn. Hence th robin-coloured feathers arose from the host's feathe germs and were coloured by melanophores whic migrated from the grafted tissue into the epiderma 'collar' of the host's feather germs.

Hybridization and Tumour Formation in Mice

C. C. **Little** (*Proc. Nat. Acad. Sci.*, 25, 452–455 1939) has shown that the first generation hybri between females of the *C57* race of *Mus musculu* d males of ***M. bactrianus*** showed a larger incidence 5·5 per cent) of tumours as compared with that the parents 14·4 per cent and 3·8 per cent respec- vely. The parental strains are different in the mount and type of tumour present, but the hybrids ave an incidence much greater than the addition of e tumour-tendencies of the parents. Also, multiple mours in one individual occur in 11·57 per cent of e F_1 and in not more than 1·14 per cent in one arental strain. Internal physiological 'unbalance' creased by hybridization is given as the most asonable cause for the results.

scular Anatomy of the Apple

THE developmental anatomy of two different arieties of apple has been studied by Mary Mac- rthur and R. H. Wetmore (*J. Pom. and Hort. Sci.*, 7, 218; 1939). The varieties McIntosh and Wagener ere chosen, as having the same chromosome number 4), a similar growth period, and distinct shape ifferences. The McIntosh apple is uniform in shape ith very faint angulation and with the stamens asal to medium in the distal depression. The agener is unequal-sided, definitely angulated, and ith stamens attached higher up. The outline of the rimary vascular bundles in the former case is rcular, and in the latter lobed, corresponding with e respective shapes of the two fruits. In McIntosh, e ventral lobes of the carpels never unite. The cules are thus never completely separated from the ntral cavity, leaving the core 'open'. In Wagener, e ventral lobes of a carpel are joined, no opening nnects the locule with the central cavity, and the re is thus 'closed'. The ovules of Wagener are ranged longitudinally with one ovule in each half f a locule. In McIntosh they are horizontal and retch across both halves of the locule or occupy the ntral cavity. This irregularity in McIntosh is sociated with irregularity in the separation and irection of the ovular traces. The authors have xamined in detail the anatomy and development of e floral parts, and in particular their ontogeny in lation to the nature of the fleshy part of the fruit. hey conclude that this is essentially a fleshy calyx ube or 'floral cup', that is, the consolidated ases of the calyx, corolla and stamens.

ontrol of Club-root

CLUB-ROOT (*Plasmodiophora Brassicae*) is normally ontrolled by correction of soil acidity and adequate rop rotation. Where applications of lime are ndesirable or ineffective, as may occur with some orticultural crops, mercuric chloride has been suc- essfully used on a small scale. Chlorinated nitro- enzenes have been tried by Margaret J. Smieton *J. Pom. and Hort. Sci.*, 17, 195; 1939) as an alterna- ive lacking the objectionable properties of mercury ompounds. Seed box experiments on white mustard ith mercuric chloride, pentachlornitrobenzene and richlordinitrobenzene showed that the latter com- ared favourably with mercuric chloride. The same ubstance applied at 1·5–3 oz. per sq. yard gave ariable control of the disease on cabbages, sprouts nd broccoli in outdoor seed beds. Mercuric chloride as, however, most effective. The trichlordinitro- enzene reduced the stand of seedlings when applied greater amount than 1¼ oz. per sq. yard. Sub- tantial control of the disease, though not always qual to that given by mercuric chloride, was obtained by the addition of a small quantity of trichlordinitrobenzene to the dibble hole at the time of transplanting. Pentachlornitrobenzene was less effective except in cases of mild attack, but was less phytocidal than the other substances. All the substances tested were liable to check the growth of the plants. With trichlordinitrobenzene the check was greater when lime was used as a diluent than when chalk or talc was used.

Exchange between Nitrogen Isotopes on Metal Surfaces

FOUR years ago Taylor and Jungers (*J. Amer. Chem. Soc.*, 57, 660; 1935) concluded that both in the synthesis and decomposition of ammonia on an iron surface the rate-determining step was $N_{2(gas)} \rightleftarrows 2N_{adsorbed}$. The correctness of this view has now been investigated by observing the velocity with which the isotopic exchange reaction $^{28}N_2 + {}^{30}N_2 = 2{}^{29}N_2$ occurs on iron and on tungsten surfaces from room temperature to 725° and 900° respectively. The exchange reaction is immeasurably slow below 450°, and even above this temperature is very slow in comparison with the exchange reaction of molecular hydrogen isotopes at the surfaces of hydrogenation catalysts. Reaction is, however, accelerated by the presence of hydrogen. To explain the slowness of the reaction two alternative mechanisms are put forward involving either (*a*) the rupture of valency bonds of adsorbed molecular nitrogen, or (*b*) if the nitrogen is adsorbed as atoms, migration of these atoms over the surface. On either hypothesis the acceleration by hydrogen is readily understood due to formation of imido or amido groups which, in (*a*), would lessen residual valency forces of adsorbed molecular nitrogen and, in (*b*), would diminish the Fe-N forces inhibiting migration. The high activation energy of approximately 50 kgm.-cal. indicates that the adsorption of nitrogen on synthetic ammonia catalysts is true activated adsorption.

Activity Coefficients of Strong Electrolytes

IT is well known that the formula of Debye and Hückel for the activity coefficient of an electrolyte holds only at high dilutions, and for moderate concentrations an empirical term involving the first power of the concentration must be added to obtain satisfactory results. P. van Rysselberghe and S. Eisenberg (*J. Amer. Chem. Soc.*, 61, 3030; 1939) have investigated the consequence of assuming a van der Waals' force of repulsion between ions, and as this is related to the mean distance of closest approach between a positive and a negative ion, which is already contained in the Debye and Hückel equation, the result is a one-parameter formula. A term proportional to the volume concentration and to the cube of the distance of closest approach, and another term proportional to the square of the volume concentration and to the sixth power of the distance of closest approach, are added to the Debye and Hückel expression for the logarithm of the activity coefficient. It is shown that precise determinations of the distance of closest approach can be made only at high concentrations, when the activity coefficients become sufficiently sensitive functions of this parameter. Activity coefficients in 0·001 and 0·01 molar solutions are calculated for several electrolytes, and in eight cases out of fifteen comparison with experimental values is possible and shows very promising agreement. The mean ionic diameters are calculated by the method of least squares.

RECENT RESEARCHES ON EARLY MAN IN CHINA. I

Late Cenozoic History of North China

P. TEILHARD DE CHARDIN opens a review[1] of the geological and palæontological evidence bearing on the late Tertiary and early Quaternary epochs in northern China by pointing out that, in the course of the past ten years, a continuous outpouring of new facts has necessitated a constant readjustment of number and relative importance of the successive physiographic stages recognizable in that part of the world, which has to be explained periodically.

Thus, the original conception of the Late Cenozoic of China as a massive and continuous formation, in which the lower and uppermost terms only (Pontian Hipparion red clays and the Pleistocene loess) were explicitly distinguished as two separate horizons, was modified through a succession of discoveries by the conception of the "Sanmenian", an intervening polymorphous complex rather vaguely referred either to the Late Pliocene or to the Lower Pleistocene. It soon became more and more clear, however, that several marked differences in species and genera were separating in the so-called Sanmenian the faunas of Nihowan and of Choukoutien, representing a definite faunal and physiographic break, the former being left in the final Pliocene and the latter representing the true Lower Pleistocene of China. The evidence has now become overwhelming that fundamental changes separate the upper (Choukoutien) and lower (Nihowan) parts of the former "Sanmenian".

Although views are still far from definite, they may be expressed provisionally as follows. Notwithstanding physiographic changes, the Equus-Camelus beds of Nihowan and the underlying pre-Nihowan (Middle Pliocene) have lithological and faunistic affinities. Both are lacustrine in facies and both are characterized by the same 'sub-tropical Asiatic' fauna. By this term it is intended to indicate that in the Middle Pliocene two different faunistic blocks were mixing in the forested steppes of north China—one of south-eastern affinities, including an abundance of Cervulids, and another, a peculiar Central Asiatic block, characterized by a harvest of beautiful, mostly strepticere, antelopes, apparently a special antelope province, parallelizing the modern African province, but separate from it since the base of the Pliocene.

The bearing on the present point is that these two blocks were still thriving in North China after the appearance of such forms (horse, bison, camel) as characterize the Villafranchian of Europe. In spite of many important differences in their respective faunas, the Middle Pliocene and Villafranchian (Nihowan) of North China are marked by the same general topography, the same climate, and the same fundamental types of deer and antelope.

These conditions being realized, it is difficult to escape the conviction that a change of the first magnitude occurred between the end of the Sanmenian (Nihowan) stage of deposition and the beginning of the following 'Choukoutien sedimentation', and that this change corresponds to a positive epeirogenic movement rejuvenating the entire Pli
cene topography. Supposing that at the end of t
Pliocene the whole of the Asiatic plateau has bee
moving upward, while a few compartments only-
Ordos (?), Fenhotrough, Peking plain—sink betwee
the rising blocks of Mongolia, Shansi, Tsinling, etc
then an increasing number of facts, so far overlooke
or unexplained, find a natural connexion and ea
explanation, among those mentioned being th
dislocation of the Pliocene lakes drained by new-c
gorges, the replacement of the lacustrine tilted
faulted sediments by thick loamy fans sloping dow
in the basins from rejuvenated ranges, the enormo
accumulations of Pleistocene sands and silts (Tientsi
800 metres; Taiyuan, 300 metres), the first appea
ance of the modern Hwang-ho, and probably the fin
separation of Japan from the continent.

As a natural consequence the antelopes die, th
Malayan deer and Stegodon retreat southward,
western or northern wave brings new types of de
(Œuryceroids, Pseudaxis, etc.), and probably fro
the south with the water-buffalo, man (Sinanthropu
appears.

Still somewhat African-looking up to the end
Nihowan times, Asia was essentially our present As
at the dawn of the Choukoutien cycle. This prov
the positive reality and gives the measure of th
post-Villafranchian break in North China.

Among conclusions which follow, it would appe
that in North China, as in France and North Indi
the first appearance of horse (more and more general
accepted by palæontologists as indicating the base
the Pleistocene in the Old World) antecedes clear
the major diastrophisms which would be the best lim
between the Tertiary and Quaternary from a ge
logical point of view; and, therefore, the advanta
of keeping the Villafranchian in the Pliocene instea
of the Pleistocene should be reconsidered. So far a
North China is concerned, the most natural bas
of the Quaternary is given by the appearance
man on a modernized topography after the Vill
franchian.

Origin of Mankind[2]

As a result of his researches on the skeletal remain
of fossil man found in the cave of Choukoutien, Pro
Franz Weidenreich maintains that the importan
body of knowledge gained from the numerous spec
mens of Sinanthropus (structure of the teeth, crani
capacity, variability of type, etc.) call for a radic
transformation of our conceptions of the problem o
the origin of mankind. The true Anthropoidea o
one hand, and the Hominidæ and Australo-Pithe
coidea on the other hand, have been derived fron
a common primitive anthropoid stock. Sinanthropu
and Pithecanthropus, representing a pre-human stag
of development, belong to the second group. Th
different specimens of the Neanderthal group repre
sent a higher, and recent man yet a third stage.

Development has been decidedly orthogenetic, an
has come about as a combination of primitive an
progressive characters. The diversion of mankin
into geographic varieties (races) is an old phenomeno

and is traceable so far back as the early stages of development of the Hominidæ. It would be wrong to suppose a polygenetic development of the Hominidæ, as the development of the common group took place only once. But the development has been polycentric, and four centres of the genesis of the Hominidæ can be distinguished—European – Western Asiatic, Middle East African, North Chinese, South-East Asiatic – Sundaic. As the development in these centres took place not at the same time and at different speeds, young and old races are to be found in every stage.

The developmental factors of Lamarckian and Darwinian conception are considered to be of no importance, the essence of evolution being an independent progressive differentiation of the type itself. The phylogenetic development is the result of internal causes, and is, like the ontogeny, an evolution of innate character.

Forerunner of *Sinanthropus Pekinensis*[3]

Certain deductions as to the character of a hypothetical forerunner of *Sinanthropus Pekinensis* are drawn by Prof. Franz Weidenreich from the skeletal material from Choukoutien. The line of argument followed is that Sinanthropus, representing the most primitive hominid known hitherto, and it being possible to connect it with recent man by a continuous line of characteristic types such as Javanthropus, Neanderthal man and the man of Mount Carmel, we may trace a picture, imaginary, but based on ascertained fact, of the forerunner of Sinanthropus in a complete and uninterrupted line of evolution, by attributing to it those specialities which, as we know, have gradually disappeared in the course of human evolution.

Thus, taking the evidence of the brain-case, its main peculiarities in Sinanthropus are the extraordinary lowness, the greatest breadth coinciding with the bi-auricular breadth, thick and far projecting supraorbital tori separated from the receding forehead by a broad and relatively deep furrow, a strong and rounded occipital torus combined with a low inion angle, and finally the location of the foramen magnum in a rather posterior level. The persistence of this bulkiness of superstructure, which in all great apes is a direct and indirect result of the misproportion of the size of the brain-case affording insufficient space for attachment of powerful nuchal and masticatory muscles, but is reduced in extent and bulkiness as the brain-case is enlarged in the course of the evolution of more advanced human types, indicates that in regard to this feature the forerunner of Sinanthropus could not have been very different from the great apes of to-day.

As to the general configuration of the brain-case, neither the relation between length and breadth, nor that between length and height, could have been considerably different from that of Sinanthropus, in whom these ratios are about the same as in the great apes.

The character of the forerunner is also suggested by the teeth, in which Sinanthropus has several features in common with the apes, but differs completely from recent man. As human evolution proceeds, the teeth undergo a reduction in size, height, length proportions and a simplification of their patterns. It is probable, therefore, that the characteristics of the teeth were still more developed in the forerunner. The canines, however, require special consideration, and there are indications that the crowns of both upper and lower canines may have been much higher in the forerunner, as is characteristic of the anthropoids of to-day. Further, the dental arcade of Sinanthropus suggests that in the forerunner the jaws were more salient.

All these facts thus outlined lead to the conclusion that the immediate forerunner of Sinanthropus was an anthropoid primate the general appearance of which with regard to skull, jaws and teeth did not differ in principle from that of female anthropoids of to-day. To know the special relations of this anthropoid-like hominid to the ancestor of recent anthropoids, we must compare Dryopithecus or Sivapithecus with Sinanthropus; but in actual fact the closest resemblance is found in neither of these, but in Australopithecus, which, therefore, must be regarded as representing an anthropoid with some relation to the anthropoid forerunner of Sinanthropus.

Such other parts of the skeletal structure of Sinanthropus as are known—or rather the collar-bone and the humerus fragment specifically—indicate that his immediate forerunner probably had abandoned the arboreal mode of living; and judging from the size of brain-case, jaws and teeth, could not have been a pygmy.

The question as to which of the anthropoids of to-day Sinanthropus bears the closest resemblance is not so easily answered as may be imagined. In some peculiarities of the teeth he approaches the gorilla (cingulum), in others (for example, wrinkles) the chimpanzee, and then again the female orang in 'taurodontism'. But when reviewed in general among all anthropoids, recent and fossil, known hitherto, Australopithecus seems to be the closest relative of Sinanthropus and his assumed forerunner.

Duration of Life in Fossil Man in China[4]

Investigation of the evidence of individual age in the remains of fossil man discovered at Choukoutien corroborates the conclusion at which Prof. H. Vallois arrived in his study of similar evidence relating to Neanderthal man, that only rarely, if ever, was death due to natural causes, and that in consequence the duration of life was not prolonged. In the Sinanthropus population, now numbering approximately thirty-eight individuals, fifteen, or 39·5 per cent, were children up to the age of fourteen years old, three skulls may have belonged to individuals aged less than thirty years old, three may range between forty and fifty years, and only one skull, that of a woman, unfortunately in a fragmentary condition, may have been that of a really old individual of more than fifty years, or even sixty years of age.

It is interesting to note that in the Pithecanthropus group, the nearest relatives to Sinanthropus, complete fusion of the sutures of the skull cap points to an age of more than fifty years, while the recently discovered third skull (1938) belongs to a juvenile.

It must be remembered that these conclusions as to age are subject to the reservation that it is assumed that the eruption of the teeth and the fusion of the sutures correspond in time to the respective processes in modern man, though it is known that in the anthropoids they take place at a much earlier age than in man. This, however, would only serve to confirm the conviction that the actual duration of life in Sinanthropus was shorter than in modern man.

With regard to late palæolithic man of the Upper Cave, of the seven individuals there were three juveniles, a fœtus or new-born infant, a child of about five years, and one of an age of fifteen to twenty years. Of the four adults, two, probably women, may have been slightly more than twenty years of age; the third is indeterminate, but probably not advanced in years, and the fourth was an old man of at least sixty years. Thus in the late palæolithic population also old age was seldom reached.

In both groups, Sinanthropus and late palæolithic man, the brevity of duration is to be attributed to the conditions of primitive life. In both groups, also, the cause of death is clear. It was due to violence—wounds inflicted by club and axe or spear as the case may be—whereas the members of the Pithecanthropus group died by accident as the consequence of a volcanic eruption.

Neither bones nor teeth show evidence of disease, while the repair of fractures and the ready formation of secondary dentine points to greater powers of recuperation than in modern man. Further, th absence of decay in the teeth suggests a resistance t bacterial infection which may account for the absenc of disease, with the doubtful exception of an arthriti affection in the vertebræ of the old man of the Uppe Cave. In undomesticated animals a natural power o resistance to disease and influences of a detrimenta character destroying the efficiency of the organ apparently compensates for the dangers of attack and extermination by their enemies, and the same may hold good of primitive man.

EIGHTH AMERICAN SCIENTIFIC CONGRESS

THE Eighth American Scientific Congress will be held in Washington, D.C., during May 10–18, 1940, under the auspices of the Government of the United States of America. Invitations on behalf of the President have been extended to the Governments of the American republics members of the Pan American Union to participate in the meeting, and scientific institutions and organizations are being invited to send representatives.

On April 14, 1940, the Pan American Union will celebrate its fiftieth anniversary. Although the Eighth American Scientific Congress will meet a few weeks after the anniversary date, the Congress will be one of the important phases of that celebration. It is hoped that the presence in Washington of many distinguished scientific workers of all of the American republics as participants in this Congress will serve as one of the many tributes to the Pan American Union for its work in the fostering of goodwill and better understanding among the republics of the western hemisphere.

This series of inter-American meetings, serving as a medium for the exchange of scientific information of particular interest and importance to the Governments and peoples of the Americas, dates from the first Latin American Scientific Congress held at Buenos Aires in April 1898 in commemoration of the silver jubilee of the Argentine Scientific Congress. The Second Latin American Scientific Congress was held at Montevideo in 1901 and the Third at Rio de Janeiro in 1905.

In 1908 the Government of Chile, which had offered to act as host to the Fourth Latin American Scientific Congress, enlarged the scope of the meeting and invited the Government of the United States of America to participate. At the same time, the name of the meeting was changed to the First Pan American Scientific Congress.

The Second Pan American Scientific Congress was in session in Washington, D.C., during December 27, 1915–January 8, 1916, and inspired a wide interest on the part of the Governments and scientific workers of the other American republics. A total of 2,566 participated in the sessions, including ninety official delegates of twenty Governments and a hundred and thirty representatives of scientific organizations and institutions in the other American republics.

The Third Pan American Scientific Congress was held at Lima, Peru, in December 1924 and January 1925. The fourth meeting in this second series of scientific congresses was held in Mexico City in September 1935, and in recognition of the continuity of the preceding conferences was designated as the Seventh American Scientific Congress. A resolution adopted at the Seventh Congress reposed in the governing board of the Pan American Union the responsibility for the selection of the date and place of the next meeting. In due course it was decided that the necessary steps would be taken to arrange for the convening of the Eighth Congress in Washington in connexion with the celebration of the fiftieth anniversary of the founding of the Union.

An organizing committee has been set up including the Hon. Sumner Welles, Under Secretary of State (*chairman*), Dr. Warren Kelchner, acting chief, Division of International Conferences, Department of State (*vice-chairman*), and Dr. Alexander Wetmore, assistant secretary of the Smithsonian Institution (*secretary*), to collaborate with the Department of State in formulating definite plans for the Congress. Dr. Wetmore has been appointed also as Secretary General of the Congress.

It has been decided that the Congress will be divided into the following sections, each to be in charge of a chairman, assisted by a vice-chairman, secretary and section committee: I, Anthropological Sciences; II, Biological Sciences; III, Geological Sciences; IV, Agriculture and Conservation; V, Public Health and Medicine; VI, Physical and Chemical Sciences; VII, Statistics; VIII, History and Geography; IX, International Law. Public Law and Jurisprudence; X, Economics and Sociology; XI, Education.

In accordance with established precedent at inter-American conferences, the official languages of the Congress will be English, Spanish, Portuguese and French. Papers may be submitted in any one of the official languages and appropriate arrangements will be made for the presentation of these papers, or résumés thereof, in the other official languages of the Congress.

MEMORIAL TABLET TO LORD RUTHERFORD AT McGILL UNIVERSITY

THE Historic Sites and Monuments Board of Canada recently presented to McGill University a memorial tablet in honour of Lord Rutherford and the work he did while in Montreal. This tablet is now placed on the outside wall of the Macdonald Physics Laboratory, McGill University. As many of the plaques and tablets prepared by the Monuments Board commemorate historic events such as battles, it is gratifying that there should be national recognition of scientific activities which, although they transcend in importance historical incidents of conflict, are so often neglected in the public recognition of important persons and events.

Tablet in commemoration of Lord Rutherford, recently presented to McGill University by the Historic Sites and Monuments Board of Canada.

A short unveiling ceremony was held in the Physics Laboratory at McGill on October 6, immediately preceding the Autumn Convocation for the granting of degrees. About a hundred persons attended the ceremony, including many old pupils and colleagues of Lord Rutherford. Sir Edward Beatty, chancellor of McGill University, presided, and a number of visitors from other universities and institutions were present. For the unveiling ceremony, the tablet was placed in the large lecture theatre of the laboratory, and surrounded by an exhibition of the apparatus used by Lord Rutherford during his nine years at McGill University, when he elucidated the phenomenon of radioactivity, and laid the foundations of much of his subsequent work. This apparatus has been admirably catalogued and described by Dr. F. R. Terroux (*Transactions of the Royal Society of Canada*, 32, Sec. III 9-16; 1938), who acts as custodian of the collection.

The ceremony was opened by Sir Edward Beatty with a tribute to Lord Rutherford, and a statement about the tablet and its formal acceptance with the gratitude of the University for this recognition. Prof. A. Norman Shaw, director of the Laboratory, referred to "the depth of feeling and the warm affection with which Rutherford is regarded in this Laboratory . . . our scientific ideals, our long and continued output of research, and the irrepressible urge to better our own limited efforts, are derived in large measure—and will continue to be derived—from the undying influence of Rutherford within these walls. It was in this very room he first announced some of the greatest of his discoveries and revealed his uncanny instinct for the next best step. Here are some of his famous pieces of apparatus which reveal the ingenuity and simple directness of much of his early work".

The Honourable Justice E. Fabre Surveyer, who is professor of civil law in McGill University, performed the unveiling ceremony, acting on behalf of the Historic Sites and Monuments Board of Canada. He said: "The Historic Sites and Monuments Board of Canada received with enthusiasm the suggestion made to it by a citizen of Montreal, Mr. Arthur J. Livinson, to commemorate by a tablet the important services rendered to science by the late Lord Rutherford. The members of the Board only divided on two questions: the site of the tablet and the date of its inauguration. Some were of opinion that the most suitable place was the house Lord Rutherford lived in while in Montreal, which, by the way, is for sale, and should, in my opinion, be secured by a friend of the University and turned into rooms for students or bachelor professors. Some also thought it advisable to postpone the inauguration so as not to affect too seriously our budget for 1939–40. Neither of these suggestions appealed to me." Eventually it was decided to place the tablet in the wall of the laboratory where Rutherford worked.

At the conclusion of the ceremony the guests remained for an informal inspection of Rutherford's apparatus, some of the essential features of which were explained by Dr. F. R. Terroux to the audience.

SCIENCE NEWS A CENTURY AGO

Davies Gilbert, F.R.S., 1769–1839

ON December 24, 1839, Davies Gilbert, president of the Royal Society from November 6, 1827 to November 30, 1830, died at Eastbourne at the age of seventy-two. Gilbert was born on March 6, 1769, at Tredrea, in the parish of St. Erth, Cornwall, his father being the Rev. Edward Giddy, curate of that place, who had married an heiress of considerable property. Educated at first by his father, he afterwards attended schools at Penzance and Bristol and in 1785 became a gentleman-commoner of Pembroke College, Oxford. He had already devoted much study to the physical sciences, and he became known as "the Cornish philosopher". In 1791, at the early age of twenty-four, he was elected F.R.S. Being free to follow his own inclinations, he left Oxford in 1793 and returned to Cornwall, acting as sheriff, dividing his time between his magisterial duties and the cultivation of science and literature, and was the friend and correspondent of Beddoes, Davy, Hitchins, Hellins, Trevithick and Hornblower. In 1804, a new sphere of activities opened for him by his election as M.P. for Helston. Two years later he was elected to represent Bodmin and he continued to sit for that borough until December 1832. "He was," says Wild, "emphatically the representative of scientific interests in the House of Commons, and contributed by his exertions to carry many very important objects. Indeed, he was continually called on to serve on committees of inquiry touching scientific and financial questions." In 1808 he married Mary Ann Gilbert, only niece of Charles Gilbert of Eastbourne and then assumed the name and arms of Gilbert.

Gilbert had a wide range of interests. He contributed papers to the *Philosophical Transactions*, and the *Quarterly Journal of Science and Arts*, was a collector of traditions, songs and carols of Cornwall, and in 1838 published "The Parochial History of Cornwall". From 1814 until his death he was president of the Royal Geological Society of Cornwall. He calculated for Telford the lengths of the chains for the Menai Straits Suspension Bridge, selected Brunel's design for the Clifton Suspension Bridge, suggested the founding of an observatory at the Cape of Good Hope, was chairman of the committee for rebuilding London Bridge, and was an advocate for the construction of Plymouth Breakwater.

J. D. Forbes, Baden Powell and Melloni

WRITING from Edinburgh on December 27, 1839, to Prof. Baden Powell, J. D. Forbes said: "I own that I should be very glad to see a good synopsis of what has been done during the last eight years, well aware that, so far as my own contributions are concerned, they were published in a form repulsive to the generality of readers, and even to many men of science who would willingly glean from your critical pages how much has been established, and on what kind of evidence, without troubling themselves about details. . . .

"I hope that you will not treat Melloni's papers so slightly as you propose. His earlier ones are full of interesting and original experiments. So far as I am concerned, I have nothing to wish but that everything Melloni has done should be fully and accurately known, for by a rare good fortune there is not a single debate in point of priority between us, and every experiment we have in common, with a single exception—the variable polarizability—cor firms each other's results. It is for you as a criti to judge how far, if in any case my right conclusion were founded on false grounds, for this is the sur of Melloni's captious criticisms."

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on before the dates mentioned

ASSISTANT LECTURERS IN AGRICULTURE at the Essex Institute Agriculture, Writtle—The Clerk to the Essex County Council, Count Hall, Chelmsford (December 30).

HEADMASTERSHIP OF THE HEREFORD CATHEDRAL GRAMMAR SCHOO—The Clerks to the Governors, A D Steel and Son, 30 Castle Stree Hereford (January 13).

LECTURER IN ENGINEERING—The Principal, Dudley and Staffordshire Technical College, The Broadway, Dudley.

SECTION ENGINEER for the Nigerian Government Railway—Th Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/9071

ASSISTANT ENGINEER in the Chief Engineer's Department of th River Great Ouse Catchment Board—The Chief Engineer, River Gre Ouse Catchment Board, Brookland Avenue, Cambridge.

SPECIALISM, DEPARTMENTALISM AND PUBLIC SERVICE

IT has long been an argument against the admission of the scientific worker to adminisrative responsibility that the specialist is too mmersed in his own particular subject to be capable of taking the wide and detached views involved in administrative decisions, and that he does not possess either the wider vision or sense of values required. Even in scientific work excessive specialization is to-day an admitted evil, and the eam work necessary in the attack on many modern problems, whether in pure or in applied cience, is already tending to break down such solation and stimulate contacts between workers in different fields, to their mutual advantage.

While, however, this charge is still freely levied against the technical or scientific expert, it is trange that the analogy of this tendency with what may be termed 'departmentalism' is usually overlooked. The departmental mind, which limits its ange to the efficiency or welfare of one particular department without regard to the efficiency of the whole, is one of the commonest causes of weakness in industrial firms and one of the greatest obstacles o the introduction of new ideas and new methods. Nor is the trouble confined to industry. How erious it can be in great Departments of State is well shown by Sir Arthur Salter in one of the most suggestive passages in his recent book, "Security: Can We Retrieve It?" Even the most efficient department tends to be innately onservative and unresponsive or unreceptive to new ideas, which are rarely fostered in accordance with their deserts, either in regard to staff or o finance.

This tendency is all the stronger if the specialized character of the department takes on the professional type and is reinforced by the characteristic conservatism of the professions. Only a detached administrator, possessing both knowledge, vision and judgment, as well as the requisite authority, can hope to override such professional departmentalism and prevent the prestige and ideas inherited from the past from blocking the effective development of new ideas. Nor is this indeed purely a technical or professional question. As Sir Arthur Salter points out in a further illuminating chapter on the personal equation, even in the administrator there is a grave tendency to adopt a purely defensive attitude, and to be occupied solely with the immediate need.

The question of executive administration and leadership to-day is indeed only partly a question of securing the effective utilization of technical knowledge. It is at least as much a question of finding and training men free from the departmental mind and outlook, who, while imbued with all the highest ideals of professionalism in respect of service and competency, are willing to accept responsibility, to face new issues frankly, to explore new methods, to accept criticism and to try bold measures when required. This is true of leadership and administrators alike in national affairs as in local government.

It is to the question of national leadership that Sir Arthur Salter directs attention; but the question of local government has been raised from this point of view almost simultaneously in an admirable broadsheet, "The Mechanism of Local Government", issued by P E P (Political and Economic Planning) and by G. M. Harris in his study of the practice of local government in ten of the largest British centres ("Municipal Self-Government in Britain", by G. M. Harris. P. S. King and Sons). These two publications set forth very clearly the problems and issues involved both in the complexities of local government and the provision of councillors and officers of the requisite calibre for their service.

In local government, as in national government, there are three basic problems: the efficient development of each particular service; smooth co-ordination of different services to ensure the reconciliation of conflicting claims within each area; and the education of the citizen to create and maintain a vital and healthy community life, through both official and unofficial channels. The stress which in recent years has been laid on the efficient development of particular services has already shown that the attainment of a certain level of efficiency by arbitrary or bureaucratic methods may obstruct rather than help the general raising of standards. It may stifle personal initiative and judgment and encourage attitudes incompatible with the spread of a sense of responsibility. Local and sectional efficiency threaten at times to strengthen departmentalism and thus to hinder the development of the community as a whole.

This factor, as well as the growing complexity of central and local government, calls for councillors and administrators of the highest intellectual capacity, and above all of the constructive type who see possibilities and opportunities rather than difficulties and dangers, and who possess creative ability and the capacity to promote energetic and far-reaching projects. Technical factors in possibly half a dozen or more fields have to be assessed, and the indirect as well as the direct effects of the proposed action or policy have to be considered. Even if the administrator himself possesses the high capacity and foresight to determine the policy which will give the maximum social result or efficiency, he may still have to convince a council or cabinet of the soundness of his judgment and proposal.

Mr. Harris's inquiry into local government provides disturbing evidence that we are not getting men and women of the requisite intellectual calibre on our local or municipal councils. The increasing demands of time alone in such service deter many of the ablest industrial leaders from taking office, apart from their frequent reluctance to engage in the small politics of local elections. An analysis of the occupation of councillors will readily demonstrate the reluctance of professional men to take up such work, and the absence of int lectual leadership is accentuated by the delibera or indirect discouragement from engaging in lo or national politics given by many large organi tions to their employees.

The position is in fact equally serious fr the point of view of elected representatives a permanent staff. The large problem now confro ing us is that of achieving further co-ordinati between the efforts of public services in differe areas and between the effort of all the differe services operating within the same area. Su co-ordination raises many issues. Even from purely technical or business angle, a high order administrative capacity and advanced techniqu are required to determine the most efficient uni and areas of operation of many different servic and for keeping their development in step accor ing to a balanced programme to be realized ov a long period of years. Even when coupled wi dictatorial powers, such a task could not be pe formed satisfactorily without a clear grasp principle, knowledge of the essential potentialiti and limitations of different services, foresight a flexibility of outlook, and a keen eye for loc conditions.

What complicates the situation is, of cours the fact that the representative bodies which co trol the administrative officers are at the san time expected to serve as a large-scale experime in adult education. However firmly convinced w may be of the value of this system of responsible sel government, we cannot in the face of the deman and dangers of to-day ignore its weaknesses exposed in practice. Ways and means must b found of delegating the discussion of administrati detail on purely technical matters on which expe advice is available, and ensuring that long-ter issues and broad questions of principle recei adequate attention from the representative bodie This means that, on one hand, some attem must be made to give the average citizen son fuller insight into the functioning of democrat methods, their method of use and appropria fields of application, and on the other hand ensure that the recruitment of staff by loc authorities is not limited by local resources bu secures the ablest and most promising tale available.

Considerations of this kind of themselves ma determine the size of areas of local governmen If the unit of administration is too small poverty-stricken, it may be impossible to staff with administrators and experts who are really competent to advise the local councillors. The methods of recruiting the most efficient staff and particularly the senior administrative officers become all the more important if they are to co-ordinate a number of large departments. Even if the size of an area is satisfactory and the authority has able officials and far-sighted councillors, efficiency will not be attained if the local government machine is faulty. Apart from the difficulties which inevitably arise in the co-ordination of departments, the traditional system of committee rule has aggravated the situation, and without a delicate adjustment of the machinery and co-ordination of committees, departmentalism may be further encouraged.

While, however, as the P E P broadsheet points out, the present internal machinery of local government can be criticized from the point of view of its ability to secure the working of a consistent long-term policy applicable to all spheres of the work of a council, this does not imply that the committee system is a failure. A committee may be efficient as a representative body, bringing with it local acceptance, or as an executive body carrying out or directing the administration, or more rarely as both. The danger is that in seeking to combine the two we fashion an instrument efficient for neither purpose. Unless clear thinking and vigorous leadership can secure the integration of objectives throughout local services, a co-ordinating body may in practice prove no more than another committee in a committee-ridden world.

It should, of course, be remembered that already regional developments in such fields as national defence, transport, power supply or the water catchment areas are beginning to modify both the sphere and character of local government. Some of the new bodies are appointed, not elected. While this may make for efficiency on the part of the full-time officers and draw into public service a considerable body of qualified people who would not stand for public election, these developments raise questions of some importance, whether from the point of view of efficiency or of self-government. The overlapping of functions of local authorities and independently appointed *ad hoc* bodies merits close consideration in the light of scientific management, as well for national as for local welfare.

The dangers of the present situation are indicated both by the P E P broadsheet and by Mr. Harris's book, and there can be no doubt as to the urgency of the problem. While the complexity of the problems of government increase, plans for improving its efficiency in a democratic society are much slower to develop. One factor in this is obviously the necessity for the education of public opinion as to the imperativeness of reform. Only under the pressure of enlightened public opinion can we hope to remedy effectively some of the weaknesses in our present system and stimulate the best brains and ablest administrators to take their place in the local and national council chambers. Much the same stimulus will be required to implement proposals already detailed for the more efficient utilization of the university graduate in local government, and for improved methods of recruiting and promoting staff. It is only simultaneously with the improvement in the recruitment of the permanent staff and the attraction of the best brains of the community to the council chamber that we can hope for the vision and leadership which will promote the constructive integration of services and administration so seriously needed. Meanwhile there is a wide field open for investigation into the size of administrative units, the comparative merits and value of different methods or techniques for their administration, apart from the exploration of such ideas as the staff college in reference to training and selection for the higher administrative posts in the permanent staff of industrial or local government or the civil service, and the much more difficult question of personal competence or qualification for executive responsibility in positions at present filled primarily on grounds of election and influence. Moreover, as the self-interest or profit motive in large-scale industry is replaced by a basis of service and team work, the problem of industrial management and leadership becomes closely allied to that of leadership and administration in public affairs. Here at least is an opportunity which should not be neglected by scientific workers any more than the responsibilities which they must accept as citizens for participating in the educational work required and in contributing their own share of service in the work of local and national government. Only as such opportunities are voluntarily seized can we expect that the services of the scientific or technical expert will be more wisely and effectively used, and the scientific administrator take the place in government which his administrative abilities as well as his scientific outlook both merit and demand.

JAMES GREGORY (1638-1675)

James Gregory Tercentenary Memorial Volume Containing his Correspondence with John Collins and his hitherto Unpublished Mathematical Manuscripts, together with Addresses and Essays communicated to the Royal Society of Edinburgh, July 4, 1938. Edited by Prof. Herbert Western Turnbull. (Published for the Royal Society of Edinburgh.) Pp. xii + 524 + 5 plates. (London: G. Bell and Sons, Ltd., 1939.) 25s. net.

THAT James Gregory was an outstanding figure in the scientific world of the seventeenth century must be generally known. The Gregorian telescope and Gregory's series are familiar evidence that he was an exceptionally gifted man. It is also known that his name, the Anglicized form of Macgregor, is that of a family distinguished in academic circles in no ordinary degree. Perhaps that celebrity owes something to the powder, wholesome but nauseous, prescribed by the great-grandson of James. At the same time it is probably less well known that in a space of two centuries this family produced a round score of men who rose to professorial or equivalent rank. But of James himself even the few who had studied his published works could have gained only an imperfect estimate. For a more adequate view it will be necessary to consult this admirable volume produced under the editorship of Prof. Turnbull for the Royal Society of Edinburgh.

The largest section of the book contains the correspondence. Of the 111 documents now printed the chief source is a collection of 57 letters at St. Andrews. These include fifty letters from Collins to Gregory. The letters from Gregory to Collins are partly reprinted from Rigaud's "Correspondence of Scientific Men" (being now inaccessible otherwise) and partly from Royal Society MSS. The other documents, less than thirty, are drawn from various sources and involve other writers. No correspondence passing directly between Gregory and Newton has been included.

Gregory's life was unhappily short. After publishing his early work, the "Optica Promota", he travelled on the Continent as far as Rome during the years 1664–1668. The greater part of the time was spent at Padua, where he imbibed the ideas of Cavalieri (d. 1647) and published two of his works, the "Vera Quadratura" and the "Geometriae Pars Universalis". The "Exercitationes Geometricae" is a short and remarkable tract published in London during the winter after his return. In the meantime, in the autumn of 1668, Gregory had been appointed to the professorship of mathematics newly founded by Charles II at St. Andrews. The last year of his life he spent as the first occupant of a similar chair at Edinburgh.

It was in 1663 and in London that Gregory became acquainted with Collins. John Collins was a remarkable man, with a gift for correspondence which has made him a pivot in the scientific history of the seventeenth century. He is described as an accountant; but as he was generally employed in government service, he may be regarded like Pepys as an early type of civil servant. Like Pepys he, too, was drawn into the circle of the Royal Society. His own special interest lay in the theory of equations, but the problem of quadratures appealed to him in his professional capacity and he had a wide appreciation of all the mathematical developments and writers of his time. Gregory, on the other hand, was cut off from the outer world and intellectually isolated at St. Andrews. He therefore found in Collins an invaluable correspondent and agent.

Each letter is here followed by editorial notes which give a lucid and succinct explanation of the allusions. Letters and notes together afford a mine of information on the scientific events and personalities of the day. On the tercentenary of the first observation of a transit of Venus, references to Horrocks have a topical interest. His "Opera Posthuma" appeared about August 1672, and reached Gregory the following spring, bringing the acknowledgment: "I received these letters ye mention, as also that box, together with the things contained, and particularly Horrocii Posthuma, for which I must acknowledge myself exceedingly engaged to you. I have perused him, and am satisfied with him beyond measure. It was a great loss that he died so young, many naughty fellows live till eighty." A month later Newton closes a letter to the same intermediary Collins with the laconic sentence: "I must joyn with Mr. Gregory in admiring Mr. Horrox."

These characteristic appreciations are familiar to readers of Rigaud. What is new is the account of an incident which might have led to a rupture between Gregory and Collins, and did in fact lead the latter in his agitated apology to pen a sentence which has fair claims to be considered the longest in the English language. Gregory had produced a series solution of Kepler's equation and Collins had offered to have it printed at the end of the "Opera Posthuma". Gregory assented, but the addition was not made. Taxed with the omission, Collins explains very late in the day that "Hickman a Bookseller the undertaker broke" and the printer refused to throw good money after bad by making any addition. Prof. Turnbull blames Collins for not keeping Gregory informed of these circumstances. Possibly also Collins may have exceeded his authority in making the original suggestion, since Wallis, not Collins, was the editor of the work. In any case the piece had only a mathematical interest, and though it must be deplored that it was not published, a book consecrated to Horrocks was not the place for it.

But valuable and interesting as the correspondence will be found, illuminated as it is by editorial comments, the book owes its most important feature to another circumstance. Gregory was a careful man and he used the blank spaces of the letters he received to record his own mathematical notes. With patient industry and no little ingenuity Prof. Turnbull has reconstructed these notes, and the result reveals the remarkable progress made by Gregory in attacking the mathematical problems of his day. Though this work was, with slight exceptions, never published, it must be taken into account in arriving at any estimate of Gregory's powers.

The notes touch on a variety of subjects. Not the least interesting are those which deal with the theory of numbers and show that Gregory, like Wallis, had entered seriously into a field in which it has commonly been supposed that Fermat reigned supreme and alone. But in view of their date, it is naturally the notes which deal with the calculus which possess the most general interest.

Since the days of the "Commercium Epistolicum" the dispute over priority between Newton and Leibniz has lost its edge. If the question is asked: Who was the inventor of the calculus, the preliminary question arises, what is meant by "the calculus"? If the answer is made to depend, as it reasonably can be, on the notation which is now associated with the operations of the calculus, the inventor was Leibniz, and about that there has never been any dispute. If the question refers to the general ideas and principles of the calculus, the invention can scarcely be attributed to one of two men, for it was the work of a generation of which the history has certainly not been fully explored yet. As to the subject, the problem of quadratures was old enough, and isolated solutions had been found as early as the Greeks. Similarly the calculation of rates of change (fluxions) could present no great difficulty when the need arose. Hence the critical step is to be seen in recognizing the inverse relation between these two processes. Now this relation was first pointed out, if in only a geometrical and limited form, by Gregory in his "Geometria pars universalis" (1668), two years before Barrow published the same result.

It is therefore of peculiar interest to follow the evolution of Gregory's ideas as Prof. Turnbull has reconstructed them. At the time, the knowledge of geometry was far in advance of what Gregory calls "analyticks" He himself was well equipped for the task of promoting this side of mathematics. In his "Vera Quadratura", where convergent sequences are explicitly introduced, he had shown an exceptional sense of the nature of infinite processes. The resulting conflict with Huygens was most unfortunate, for Huygens was essentially a fair-minded and generous man, as he showed afterwards when he recommended Gregory for a position in the Paris Academy. It was from the geometrical side that Gregory approached the subject, and indeed by calculating the subtangents of curves ($y. dx/dy$). Only later he recognized the primary significance of the derivative, and from this point he was quickly led to the process of successive differentiation. Armed with this weapon, he used his results to calculate power series and thus anticipated Taylor's theorem by nearly half a century. It has always seemed strange that this discovery was reserved for Brook Taylor; perhaps Colin Maclaurin appears a more natural heir to his own part of the legacy. But Prof. Turnbull has now shown that Gregory was in effective possession of the secret. By his failure to publish the method not only has Gregory lost his due recognition, but also, what is more important, the progress of mathematics must have been retarded at the time. As it is, while applications of the method by him have been established, there is no trace of a general proof. It is also to be noticed that there is no sign of any attempt to devise or employ an appropriate notation. Apparently Gregory felt no need for one. He was working for his own satisfaction.

Gregory's short life closed in 1675. The date and the shortness of the span combine to make what he accomplished remarkable. The more important formulæ of interpolation were his discovery. So was the general binomial theorem, under the guise of finding "the number of a logarithm". A set of excellent essays on the published works of Gregory completes the work, and suggests that a valuable source of information has been too little regarded. But the feature which distinguishes this from the generality of memorial volumes is the reconstruction of Gregory's fragmentary original notes. Under Prof. Turnbull's expert guidance it is possible to look over the mathematician's shoulder and see him actually at work. For this reason the book is not only a valuable contribution to the history of mathematics: those who are interested in the subject cannot fail to find it as fascinating as it is instructive.

H. C. PLUMMER.

CHEMISTRY OF THE ALKALI AND ALKALINE EARTH METALS

Gmelins Handbuch der anorganischen Chemie Achte völlig neu bearbeitete Auflage. Herausgegeben von der Deutschen Chemischen Gesellschaft.

(1) System-Nummer 22: Kalium. Lief 4: Verbindungen bis Kaliumacetat. Pp. 805–932+xxv. 15 gold marks.

(2) System-Nummer 22: Kalium. Lief 5: Verbindung bis Kalium und Wismut. Pp. 933–1074. 19.50 gold marks.

(3) System-Nummer 24: Rubidium. Pp. xviii+x+250. 31.50 gold marks.

(4) System-Nummer 25: Caesium. Lief. 1: Verkommen, Darstellung und Eigenschaften des Metalls. Pp. 104. 12 gold marks.

(5) System-Nummer 25: Caesium, mit einem Anhang über Ekacaesium. Lief. 2: Verbindungen des Caesiums, Ekacaesium. Pp. xx+105–268+ix. 21.75 gold marks.

(6) System-Nummer 27: Magnesium. Teil B, Lief. 1: Verbindungen bis Magnesium und Jod. Pp. vii+200. 23.25 gold marks.

(7) System-Nummer 27: Magnesium. Teil B, Lief. 2: Verbindungen bis Magnesiumcarbonat. Pp. 201–330. 15.75 gold marks.

(8) System-Nummer 27: Magnesium. Teil B, Lief. 3: Verbindungen bis Magnesium und Wismut. Pp. 331–422+xiv. 12 gold marks.

(Berlin: Verlag Chemie, G.m.b H., 1937–38.)

(1, 2) SECTIONS 4 and 5 of the volume on potassium of this great work deal with its compounds with boron, silicon, phosphorus, arsenic, antimony and bismuth. Three derivatives of the boranes have been identified, namely, $K_2B_2H_6$, $K_2B_4H_{10}$ and $K_2B_5H_9$, of which the first is the most stable. Stock and his collaborators have shown that although boroethane acts as a dibasic acid, it is also unsaturated, so that when potassium acts upon it the ionized hydrogen is not discharged but is used to saturate the boron complex, its charge being transferred to the metal: $H_2(BH_2:BH_2) + 2K = K_2(BH_3.BH_3)$. On hydrolysis of the product, a dihydroxydiborane $K_2[H_4B_2(OH)_2]$ is formed, which was formerly regarded as a hypoborate, KH_3BO. Further hydrolysis yields potassium metaborate. The existence of five anhydrous and three hydrated potassium borates is indicated on the phase-rule diagrams, but only one borofluoride is mentioned.

In dealing with the manufacture of potassium carbonate, although many different methods are given, chief stress is laid upon the Engel-Precht process from sylvine and magnesium carbonate and the electrolytic process. The manufacture of potassium cyanide is dealt with fully and some organic salts are also described. Varying results seem to have been obtained for the solubility of potassium bitartrate according to the method chosen.

The constitution of the metaphosphates of potassium is not yet completely established. Only polymeric forms appear to exist, namely, tri-, tetra- and hexametaphosphates. The hexametaphosphate is obtained as a hygroscopic mass by precipitating the lead salt and allowing it to react with potassium sulphate. On heating this to 660° C. the insoluble Kurrol salt is formed. There is also some uncertainty as to the actual constitution of the antimonate and of tartar emetic, for the latter of which three possible structures are suggested.

(3, 4) The heavy alkali metals rubidium and cæsium are both obtained from artificial carnallite, a by-product in the extraction of potassium from the mineral, which contains 0·02 per cent of rubidium chloride and only 0·0002 per cent of cæsium chloride. By the action of water much of the potassium chloride can be crystallized out, when both rubidium and cæsium may be precipitated from the concentrated mother-liquor as silicomolybdates. The molybdenum is then removed by volatilization as oxychloride in a current of hydrogen chloride. From an acid solution of the residue, potassium and rubidium free from cæsium can be precipitated as chlorides by addition of alcohol, and antimony chloride will precipitate cæsium antimony chloride free from the other alkali metals. The rubidium is freed from potassium by repetition of the silicomolybdate process. It is obtained pure by the electrolysis of the fused hydroxide. Iron wire surrounded by magnesite is used as cathode and two diaphragms are needed to protect the metal from anodic oxidation.

Cæsium is obtained chiefly from the mineral pollucite, a cæsium aluminium silicate found in the felspar quarries in the State of Maine, U.S.A. It can be obtained pure from its cyanide by electrolysis, and on account of its low melting point (28·6° C.) it can be filtered under petroleum. The metal is used in the construction of photo-cells and thermionic valves. Very thin layers of cæsium on a metallic surface give a much stronger photo-electric effect than compact layers, but the action is rather complex. Up to a certain minute thickness, while the cæsium is held solely in the form of *ions* on the surface it produces no selective effect, the photo-emission proceeding entirely from the under layer of metal. Beyond that point *atoms* of cæsium begin to be adsorbed which can themselves emit photo-electrons, but when the layer is about one atom in thickness reversal of the dipoles occurs with a consequent shift of the photo-chemical threshold towards shorter wavelengths.

Rubidium chloride and bromide become coloured under the influence of radium or X-rays, and rubidium tri-iodide, unlike potassium tri-iodide, can be obtained in the anhydrous form. The rubidium salts of the tartaric acids show reversal of sign in optical rotation for sodium light.

(5) Compounds of cæsium, though similar to those of other alkali metals, exhibit certain peculiarities. Thus we find no fewer than four sub-oxides in addition to the basic monoxide and the two peroxides, and although the fluoride crystallizes like sodium chloride and other alkaline halides in face-centred cubes, the chloride, bromide and iodide of cæsium assume the body-centred cubic lattice. Of the last three compounds the chloride alone is dimorphous, its crystal form changing at about 445° C. to the face-centred type. Again, various polyhalides such as $CsBr_3$, CsI_3, CsIBrCl, etc., have been isolated in stable unsolvated form. The cæsium analogue of tartaremetic has been prepared and like the latter is now formulated as a co-ordinated aquo-salt $Cs[Sb(C_4H_2O_6).H_2O].\frac{1}{2}H_2O$.

Many attempts have been made to isolate element No. 87, Mendeléeff's eka-cæsium, but so far the evidence of its existence rests on a somewhat slender basis. If the element exists at all, it appears to be extraordinarily scarce. In 1929 Papish and Wainer obtained several alums from the alkalis extracted from samarskite, a mineral rich in uranium, and after repeated recrystallizations the fraction richest in cæsium and poorest in potassium was found to give five of the X-ray spectral lines calculated for eka-cæsium by Moseley's rule. Examination by the mass-spectrograph of this alum indicated the existence of ions of mass 220 ± 1 at 600–700° C., but their intensity was about 10^{-4} of that of the cæsium ions.

(6, 7) Compounds of magnesium with most of the non-metals are described in Parts B 1 and 2. At present only spectrographic evidence is available of the existence of a hydride. The oxide is very stable and is not reduced by hydrogen at 2,500° C. under a pressure of 150 atmospheres. The dioxide has not been obtained in the pure state, but by the action of hydrogen peroxide on salts a product rich in oxygen has been obtained which gives a stable compound, $MgO_2.3MgO.Aq$, on exposure to air. In addition to the well-known nitride, magnesium yields an explosive azide MgN_6, a diamide, a hexammine and many co-ordination compounds with organic bases.

The hydrolysis of magnesium chloride by water vapour occurs in two stages, the formation of basic salt being exothermic, whereas above 505° C. an endothermic decomposition to oxide occurs. On the other hand, the salt is not hydrolysed by liquid water even under pressure, although the solution has a strong corrosive action on metals and alloys. At room temperature, pyrites is oxidized in presence of a solution of magnesium chloride to ferrous sulphate and sulphuric acid. Magnesium chlorate and its tri-hydrate are very powerful dehydrating agents, the anhydrous salt being twice as effective as the hydrate. Both can be used with advantage for drying gases; and since they are neutral in reaction, have a greater capacity for absorbing water than phosphoric anhydride, do not become pasty on exposure to air and can be regenerated after use, they may be regarded as superior to other dehydrating agents. The tri-hydrate can absorb about 20 per cent of its weight of water to form the hexahydrate. As it yields a hexammine, it is not suitable for drying ammonia.

Magnesium sulphide can be obtained in an exceptionally pure state by the action of carbon disulphide on magnesium sulphate in a current of nitrogen at 700–900° C. It is not luminescent unless it contains traces of other metals with smaller atomic diameters than magnesium. The colour of the phosphorescence depends on the foreign metal.

Several hydrates of the sulphate are known; the anhydrous salt is not obtainable from a solution in water, but can be prepared by careful dehydration of the heptahydrate, although hydrolysis is apt to occur during the process. The dehydration of magnesium carbonate tri-hydrate is generally accompanied by loss of carbon dioxide unless the experiment is carried out in a closed vessel, when the basic salt which is first formed slowly reabsorbs the gas to form the anhydrous salt. The precipitation of *magnesia alba* is a rather complex process. When the proportion of sodium carbonate to magnesium sulphate in solution is insufficient to cause precipitation, magnesium carbonate trihydrate can be crystallized out, whereas excess of the alkali will precipitate a basic salt. A table is given showing the composition of the mother-liquor resulting under various conditions.

(8) In this part will be found accounts of salts of magnesium with a few of the commoner organic acids, together with compounds containing silicon, phosphorus, arsenic, antimony and bismuth.

Naturally occurring silicates of the metal are dealt with elsewhere, although the phase-rule diagram of the system MgO : SiO_2 is given and also full details of the physical properties of the anhydrous orthosilicate and the varieties of metasilicate, namely, clino-enstatite, enstatite, and the monoclinic and rhombic amphiboles. The phosphates present some rather formidable structural problems on account of their number and variety.

It would be interesting to discover the orientation of the stable salt $Mg_3(PO_4)_2.22H_2O$, which Bassett and Bedwell observed to change to the octahydrate, in presence of the mother-liquor, in the course o a few weeks. The work of these authorities on the glowing of orthophosphates and pyrophosphate might have been given in fuller detail, particularly their observations on the heat evolution on glowing and their co-ordination theory of the structura changes which accompany the glow. A structura formula has recently been assigned by Beintema from X-ray analysis to magnesium antimonate $MgO.Sb_2O_5.12H_2O$, in which six molecules of water are co-ordinated with the cation and six hydroxyl groups with each of two anions, thus : $[Mg(H_2O)_6]\,[Sb(OH)_6]_2$.

CLIMATE AND MAN

Klima, Wetter, Mensch

Von E. Brezina, W. Hellpach, R. Hesse, E. Martini, B. de Rudder, A. Schittenhelm, A. Seybold, L. Weickmann. Herausgegeben von Heinz Woltereck. Pp. viii + 446. (Leipzig : Quelle und Meyer, 1938.) 18 gold marks.

THE subject of this book is climate and weather as part of man's environment—*Lebensraum* in the literal sense—including not only the natural air of the free countryside, but also the modified air of great cities, houses, air-conditioned buildings and, on a still smaller scale, within clothing. These studies on the borderlands of meteorology and biology or medicine are highly specialized, and they are dealt with in a series of memoirs by different authorities. In the first and longest section, Prof. L. Weickmann sets out the fundamental basis, the elements of climate and weather. This is to some extent orthodox meteorology, but with a difference. It starts with a detailed account of solar radiations of all wave-lengths and their biological effects ; other climatic elements in turn are treated from the same point of view. 'Sensible' temperature and the cooling power of air are fully discussed, while for humidity the important quantity is taken as the physiological saturation deficit.

The processes of weather come next ; here the biological aspect is to some extent lost sight of, and the author is drawn aside into his favourite topic of rhythms in barometric pressure. This is followed by an account of seasonal and other long-period weather changes, and the section ends with a thorough and interesting account of the modern study of micro-climatology, the effect of small surface features—hills and valleys, streets, forests and growing crops. These minute studies have been pursued very thoroughly in Germany in recent years, and the book contains a great deal of information which is not otherwise readily available, as well as some striking illustrations.

In the rest of the book the emphasis is mainly on the biological aspect. B. de Rudder has an important memoir on the basis of human bioclimatics, divided into the influence of the separate climatic elements, of climate in general and of weather (meteorobiology). Solar radiation still holds pride of place, from such diverse aspects as rickets, sunburn, and the coincidence between outbreaks of cerebro-spinal meningitis and sunspot maxima. In questions of bioclimatics there are still plenty of unknown quantities. A. Schittenhelm deals with the curative factors of different types of climate, stressing the need for medical advice in selecting the correct treatment, for example, for nervous diseases. E. Martini describes the part played by climate in the causation of disease—a highly complex subject involving the life-history of the organisms responsible for epidemics such as malaria, which is treated at length. The remaining chapters, comparatively short, are : Man in an Artificial Climate (E. Brezina) ; Plants, Climate and Weather (A. Seybold) ; The Animal and the Climate (R. Hesse) ; and Culture and Climate, by W. Hellpach, a philosophical essay on 'culture', relating not only material civilization but also political development, religion and other spiritual values to the natural environment, of which climate is an important part.

The book is well printed, but in the Gothic type which he who runs (or travels by train) finds difficult to read. There are no exact references, merely citations of a few names ; there is no bibliography and no author index, so that it is very difficult to follow up or find the authority for any particular statement.

C. E. P. BROOKS

A SYNOPSIS OF GENETICS

An Introduction to Genetics
By Prof. A. H. Sturtevant and Prof. G. W. Beadle.
Pp. 391. (Philadelphia and London: W. B. Saunders Co., Ltd., 1939.) 14s. net.

THE increasing number of publications of recent years which deal with the subject of inheritance is testimony to the keen interest in the laws and principles of this science. Our knowledge of it increases daily through the research activities of universities, experiment stations and other institutions, and it is becoming exceedingly important now to disseminate this knowledge in order to make further progress possible. Genetics is taught in the universities of the United States as an important subject in biology, and in Great Britain, where the teaching of biology is still backward, genetics has been given the place of a Cinderella. A few years ago it was perhaps sufficient to acquaint the student only with Mendelian ratios; nowadays, however, the rapid advancement of genetical discoveries makes it necessary to study in greater detail the intricate mechanism by which characters are transmitted.

At present there are several introductory textbooks. All have some defects due chiefly to over-simplification, omissions, or lengthy discussions of insignificant details, which prevent these textbooks from satisfying in all respects the needs of teachers and students of genetics. The book under review is written by two well-known authors, and it is planned as an introduction to genetics for the use of students with an elementary knowledge of biology. The senior author is one of those pioneers who are responsible for the foundation of modern genetics; to him we owe much of our concept of the linear arrangement of genes in the chromosomes and the construction of the first chromosome map. Dr. Beadle's researches on maize genetics are widely recognized, and his recent contributions in collaboration with Dr. B. Ephrussi have opened up a new approach to the study of the developmental properties of the hereditary material. Obviously, a book written by such eminent authors should be judged by a high standard.

The order in which the material is presented is claimed to be a natural one and the reader will find the approach to genetics entirely novel. The opening chapter deals with the inheritance of sex, sex being the most widely spread and generally recognized discontinuous character and the mechanism underlying its inheritance the most simple and easily understandable. The other chapters follow in logical sequence, though it is difficult to explain why Chapter xv, inheritance in trisomics and tetrasomics, is separated from that on polyploidy (Chapter xix) by discussions on sex determination, population genetics and selection. An encyclopædic tendency is often revealed by bringing together apparently unrelated phenomena; for example, Chapter xvii, which deals with multiple genes, also includes a discussion on asexual reproduction and identical twins.

Throughout the book emphasis is laid on the mechanical aspect of heredity. Mendelian laws and probability expectations are presented in a way that will soon convince the student that genetics is a 'mathematically developed subject'. Nothing has been omitted which will help to elucidate to the student the method of character transmission. The authors direct special attention to crossing-over, a process responsible for new combinations of characters. It is the first textbook of genetics in which the consequences of crossing-over are presented correctly; crossing-over is described as an event which takes place during the meiotic prophase when the associated homologous chromosomes are in the four-strand stage, and its products are interpreted in this sense throughout the whole book. To illustrate the various characteristics of the process of crossing-over, the behaviour of attached-*X* chromosomes in Drosophila is presented at great length. One may wonder, however, why the authors failed to direct attention to the effects of age, sex and temperature upon crossing-over, since these are of practical importance. Teachers and students will regret that the various topics are discussed too briefly, for while in this way the student can get a clear idea of the principles involved, he will need a teacher's assistance to understand all the essentials. This difficulty will become obvious in working out the problems, for in many cases the student will not be able to solve these very interesting and instructive problems unless he makes use of the references quoted at the ends of the chapters.

The authors, wishing to appear impartial and objective, confine themselves to a strict presentation of facts. Certain data are recorded without any interpretations whereas others are completely omitted, presumably because the authors do not consider them proved experimentally. This alone is probably the reason for omitting an account of Haldane's interesting method and results relating to partial sex-linkage and the first chromosome map in man. No reference is made to Fisher's theory of dominance, which as a scientific thought is worthy of report. As an example of where caution can be excessive, we should like to direct attention to a statement (p. 301) that new shoots which develop from the callus tissue in decapitated tomato seedlings "for some unknown reason" are frequently tetraploid. It would appear entirely reasonable—and it is moreover supported by Mather's observation (*J. Genet.*, **27**, 127; 1933)—that somatic doubling of chromosomes may have resulted from failure of wall formation in the dividing cell, followed by a fusion of the two nuclei during the next resting stage or division. May not such extreme caution in avoiding references to plausible suggestions defeat the very purpose of the book, namely to stimulate thought and inspire inquiring reasoning in the student?

However, these few criticisms cannot belittle the great value of the book. The most striking impression which the reader gets is of the great wealth of information which has been condensed into the twenty-three chapters it contains. Much of this has been gained by the personal experience of the authors. Various genetical phenomena, especially those which have been experimentally tested, for example, homozygosis attached-*X* chromosomes, ring chromosomes. somatic crossing-over, preferential segregation and others too numerous to mention, which are either omitted or only briefly dealt with in other text-books, are here described and explained in detail. The diagrams are particularly excellent and instructive. It is evident that the authors' interests are centred in Drosophila and maize genetics, most of the examples given to illustrate the working mechanism of heredity being taken from these fields—perhaps more than are necessary. The novelty of presentation and inclusion of fresh material render this book a particularly important contribution to genetical literature, and its value will be fully appreciated only when it has been in use. The book is comprehensive, up-to-date and reliable, and the information which it contains is accurate—thus it can claim to be more than a text-book; it will be regarded by many a teacher and student as a veritable encyclopædia of genetics.

P. C. KOLLER.

RADIO-COMMUNICATION

(1) The Elements of Radio-Communication
By O. F. Brown and E. L. Gardiner. Second edition. Pp. viii + 551. (London: Oxford University Press, 1939.) 16*s*. net.

(2) Télégraphie et téléphonie sans fil
Par C. Gutton. (Collection Armand Colin: Section de physique, No. 6.) Neuvième édition entièrement refondue. Pp. 183. (Paris: Armand Colin, 1939.) 15 francs.

(3) The Radio Manual
For Radio Engineers, Inspectors, Students, Operators and Radio Fans. By George E. Sterling. Third edition. Pp. vi + 1120. (London: Chapman and Hall, Ltd., 1938.) 25*s*. net.

THE science and practice of radio-communication have, during recent years, advanced at such a rate that it is desirable that the books dealing with fundamental principles should be revised to keep abreast of the progress, and also that new books or monographs should deal in an up-to-date manner with the latest phases or applications of the subject.

(1) The first book under consideration here was produced by the first-named author about twelve years ago, and a second edition has now been prepared in co-operation with the second author. This work gives a comprehensive survey of the elementary principles underlying radio-communication and is suitable either for the general reader or for the student making an early acquaintance with the subject. Although it is almost entirely devoid of mathematics and formulæ, the treatment of the whole subject is on a very sound and easily understood basis. This second edition covers the whole subject from the generation and study of high-frequency oscillations to their application in the various forms of radio-communication, including telegraphy, telephony, broadcasting and television.

In covering this wide field, the authors have very wisely avoided giving any detailed attention to those specialized sections of the subject which are adequately treated in other works, to which the serious student may refer. They rightly suggest that this work forms a useful elementary text-book on the subject, and with the view of enhancing its utility in this respect, a number of questions have been appended to each chapter, the majority of these questions having been extracted from the examination papers of various technical institutions granting certificates to successful candidates.

The general production of the book is very good; misprints are rare, but it would have been an advantage if more of the chapters had been sectionalized and provided with sub-headings.

(2) Although the second book under notice is

described as the ninth edition, it is explained in the preface that the text has now practically been rewritten in order to produce a comprehensive survey of the principles of radio-communication in the light of modern knowledge and practice. The subject is treated in a general but not too elementary manner, it being assumed that the reader has some slight acquaintance with electrical circuits and alternating currents. The volume is of a very handy pocket size and should be appreciated by those who desire a general survey of the subject in the French language.

(3) The sub-title of the third book indicates the class of reader for whom it has been especially prepared, namely, those engaged in the production, operation, inspection or maintenance of radio-communication apparatus of all types. The first edition of the work was published in the United States some ten years ago, and it has undoubtedly been a success in its right sphere. The present edition of more than a thousand pages is a working manual of the practice of radio-communication on land, at sea, and in the air, with illustrated descriptions of the equipment used, and including detailed explanations of the general regulations and operating procedure appertaining thereto.

So far as the publication of the book in Great Britain is concerned, its usefulness is severely limited by the fact that the majority of the systems, apparatus and regulations described are representative of American practice, and so they are not of general direct interest to those engaged in radio-communication outside the United States.

R. L. S.-R.

STEAM DATA

(1) Abridged Callendar Steam Tables

By the late H. L. Callendar, revised by G. S. Callendar. Fourth edition. Centigrade Units. Pp. 8. 1*s*. net. Fahrenheit Units. Pp. 8. 1*s*. net. Charts for above. 18½ in. × 16 in. 6*d*. net each. (London: Edward Arnold and Co., 1939.)

(2) The 1939 Heat-Entropy Diagram for Steam Plotted from the 1939 Callendar Steam Tables

Based on Research by Prof. A. C. Egerton and G. S. Callendar. (Published for the British Electrical and Allied Industries Research Association.) 38½ in. × 33½ in. (London: Edward Arnold and Co., 1939.) 4*s*. net.

(1) IN association with the 1939 Callendar Steam Tables [Fahrenheit Units] there have also been published, in convenient octavo pamphlet form, two sets of Abridged Callendar Steam Tables. These, which are now in their fourth editions, are available both in centigrade units and in Fahrenheit units, and appropriate to each there has also been prepared a total heat-entropy chart, 15 in. × 18 in.

In these tables and charts a considerable amount of revision has been effected in order to bring the figures presented into accord with the results of recent work in this field of research. To meet also the extending needs of those concerned with the design, testing and operation of steam plants, the values have been carried on to a pressure of 3,000 pounds per square inch. Included are a number of equations for saturated steam and general equations for steady flow, so that for most general purposes these publications supply such information as will be required at very moderate cost—a consideration which should place them within the reach of students.

(2) Where, however, the nature of the work demands more extensive data and a chart of larger scale, the 1939 Heat-Entropy Diagram for Steam is now available. This is of large size, on a sheet 38½ in. × 33½ in., and has been plotted from the 1939 Callendar Steam Tables based on research by Prof. A. C. Egerton and Mr. G. S. Callendar, on behalf of the British Electrical and Allied Industries Research Association. It has been produced in three colours and, as a result, any one of its closely grouped series of lines can be followed with ease to the desired point or vice versa. The lattice on which the diagram is plotted and which represents co-ordinates of entropy and heat is shown in green, the scales being 1 cm. to 0·01Φ and 1 cm. to 10 B.Th.U. per pound. The pressure, temperature and dryness curves are in black, while those of volume and superheat appear in red. Recalling the trend of these several curves in this type of chart, it will readily be seen that the arrangement adopted is the most favourable to ease of interpretation.

The care which has been taken in plotting the vast number of values which have been necessary for the preparation of so extensive a diagram, and the remarkable accuracy with which it has been reproduced in three different colours, reflect the highest credit on those responsible for the original and on those also to whose technical skill its reproduction is due.

TISSUE RESPIRATION

By Prof. R. A. Peters, F.R.S.,

Department of Biochemistry, Oxford

A DISCUSSION on tissue respiration was organized for August 31 jointly between Sections B and I (Chemistry and Physiology) of the British Association at Dundee. Owing to the imminence of war several of the proposed speakers were unable to attend, namely, the organizer and opener Prof. R. A. Peters, Dr. Malcolm Dixon, Prof. H. Theorell, Dr. D. E. Green and Dr. T. Mann. Prof. D. Keilin also did not attend. Prof. H. S. Raper, who was intending in any event to give a contribution towards the end of the discussion, kindly offered to introduce the subject and ably substituted for the absent speakers, so that the comparatively large attendance was not in vain. In order to give a more comprehensive survey of the subject, it has been thought advisable to follow in this account the lines of the addresses as originally planned.

To make a coherent account of tissue respiration for the benefit of those unfamiliar with it, the subject was divided into the parts concerned with the organized tissue cell and those relating to the isolated tissue component. Starting with the present position of knowledge of the isolated components, the discussion worked through to the respiration of the more highly organized tissue slice, and ultimately to the chemical control of the whole system.

The address of the opener was intended to deal briefly with the historical background, pointing out that the subject had roots in the distant past, but had developed rapidly only in the most recent years. In a short time it was clearly impossible to do justice to the work of the pioneers; but the following must be especially mentioned: the importance of Wieland's theories of hydrogen activation, of Hopkins' isolation of glutathione, of Thunberg's methylene blue technique, of Keilin's cytochrome, and of the various contributions from Warburg and his co-workers and from the Stockholm school under von Euler. Much advance in knowledge had come from the use of the *in vitro* study; to allay any doubts as to the value of the isolated tissue preparation, it must be emphasized that in studies at Oxford there has been found to be a remarkable parallelism between the improvement of respiration in the avitaminous pigeon's brain by the addition of vitamin B_1 *in vitro*, and the similar action of the latter in curing symptoms of deficiency *in vivo*. Such studies form a valuable bridge for the interpretation of *in vivo* happenings by the use of *in vitro* preparations. Owing to the short time available, some important aspects of the subject had to be pruned, among them being glutathione, vitamin C, oxidation-reduction potential in relation to tissue respiration processes, adequate discussion of the Szent-Györgyi catalytic system of C_4 acids, also the plant oxidase reactions, which, though not strictly tissue respiration in the animal in this sense, have been so valuable a feature of contributions from the laboratory of Prof. Raper.

Dr. Malcolm Dixon's introductory address (Cambridge) dealt with the general subject "Catalysis in Respiration". Defining tissue respiration as the utilization of molecular oxygen for the oxidation of organic substances in tissues, Dr. Dixon stressed the fact that tissue respiration is essentially a problem of catalysis, and dealt with the questions: How do the catalysts work? What is their chemical nature? And how do they cooperate in respiration? Owing to recent work, the main features of this mechanism are now fairly clear. We have the two types of respiratory catalysts, the *activators* and the *carriers* respectively. "The *activators* are enzymes, very highly specific in many cases, which combine in a loose but highly specific way with their substrates, so that the combined substrate is reactive". The *carriers* work differently; though mostly not enzymes, they enable two compounds which we may designate AH_2 and B, incapable of reacting with one another directly, to react through their agency along the lines of equations 1 and 2:

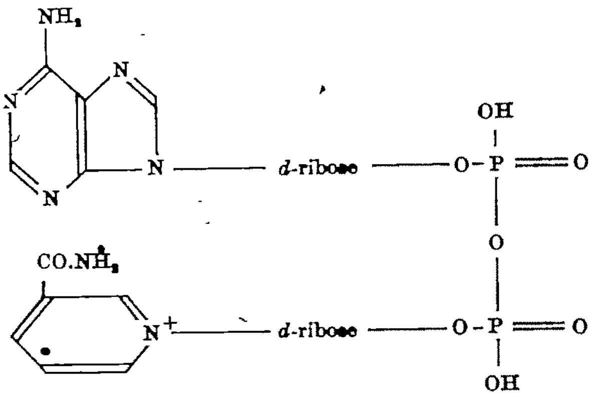
$$AH_2 + C = A + CH_2 \qquad (1)$$

$$CH_2 + B = C + BH_2, \qquad (2)$$

in which 2H is so transferred from A to B. Since the organic 'substrates of respiration' are oxidized in an ordered series of successive reactions (steps of 2H at a time), a large number of activating catalysts is involved; about twenty-five distinct dehydrogenases (enzymes concerned in H transfer) are known. There is the further complication that activated substrates require further carriers to bring them into relation with molecular oxygen. As an example,

$$\underset{\text{(Triosephosphate D)}}{\overset{(1)}{\text{Triosephosphate}}} \rightarrow \overset{(2)}{\text{CoZ}} \rightarrow \overset{(3)}{\text{FP}} \rightarrow \underset{\text{(Cytochrome oxidase)}}{\overset{(4)}{\text{Cytochrome}}} \rightarrow \overset{(5)}{O_2} \qquad (3)$$

FP = Flavoprotein D = dehydrogenase



COZYMASE

Fig. 1

In such a scheme H is transferred in the direction of the arrows. The carrier cozymase (CoZ) (Fig. 1) is very important. It is a compound of adenylic acid and nicotinic amide-ribose-phosphate, in which the essential group is the nicotinic amide; one double bond of this is capable of reversible reduction. The cozymase like the triosephosphate combines loosely with the dehydrogenase; the enzyme then catalyses the bimolecular reaction which results in the oxidation of the triosephosphate and reduction of the cozymase. The latter then combines loosely with the flavoprotein and becomes re-oxidized. In its turn the reduced flavoprotein reduces Keilin's cytochrome *C*, a specialized hæmochromogen, the latter being oxidized by oxygen in presence of the enzyme cytochrome oxidase. This means that the real function of respired oxygen is to keep the tissue cytochrome in an oxidized state; and that the oxidations of tissue constituents are really a succession of H transfers from them to the oxidized cytochrome, sometimes interpolated with reactions involving the addition of the elements of water.*

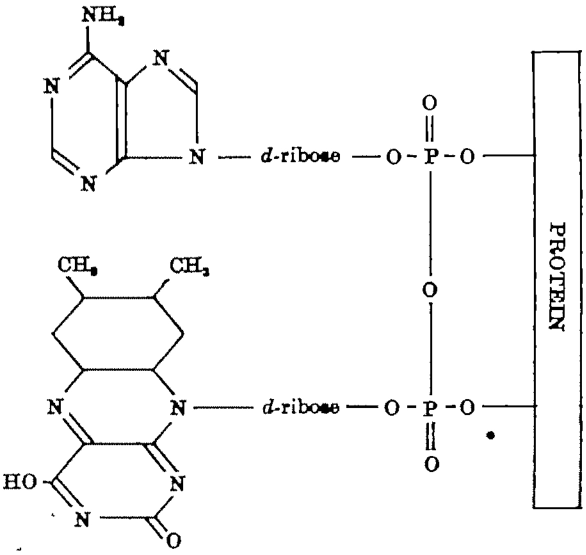
It is important to realize that these enzymes are quite general for both yeast and animal tissues. Parts 2, 3, 4 and 5 of equation 3 are common for the oxidation of many different substances; only the dehydrogenases are different; the reactions in which cozymase plays a part are reversible and in the absence of oxygen the dehydrogenase systems may react with one another through cozymase, producing fermentations. Dr. Dixon concluded by reference to known variations upon the main theme. In some cases there is a substitution of coenzyme · II (triphosphopyridine nucleotide) for cozymase; there exists a small group of dehydrogenases which react direct with cytochrome; Szent-Györgyi has produced evidence that in total respiration a definite part is played by the C_4 dicarboxylic acids (fumaric, etc.) which bring about the oxidation of reduced cozymase by cytochrome in an indirect way. Dixon further pointed out that most links in the chain can be represented artificially with other substitutes such as dyes. The use of methylene blue instead of molecular oxygen plus the cytochrome system is the basis of the well-known Thunberg method of investigating dehydrogenases.

Dr. Dixon's succinct but comprehensive paper was to be followed by Dr. Theorell (Sweden), dealing with the developments in our knowledge of the flavoproteins (Fig. 2). These are compounds of proteins with the component of the vitamin B_2 complex, which is known as riboflavin, di-methyl-alloxazine-ribose-phosphate. The old yellow ferment of Warburg and Christian, which was finally obtained in quite pure condition by Theorell himself, and which consisted only of riboflavin-protein, is probably an artefact. In its place now six new flavoproteins have been described. All of these have as their prosthetic group riboflavin and adenylic acid, called after Warburg alloxazine-adenine-dinucleotide; the protein component differs.

FLAVOPROTEINS

No.	Transfers H between		Workers	Source
1.	O_2; di-H_2-pyridine		Warburg and Christian	Yeast
2.	O_2; amino-acids	Krebs' *d*-amino-acid oxidase	Das, Straub, Warburg and Christian	Kidney
3.	Meth. blue; di-H_2-pyridine		Haas	Yeast
4.	O_2; xanthine	Xanthine oxidase	Ball, Green	Milk
5.	Cytochrome; di-H_2-pyridine		Corran and Green	Milk
6.	Cytochrome; di-H_2-pyridine	Diaphorase	Green, von Euler, Straub	Heart muscle

With the exception of No. 1, all have protein



FLAVOPROTEIN (STRAUB)

Fig. 2

---

* Such a view of the function of respiratory oxygen is revolutionary as compared with views of, say, ten years ago.

components different from the original Warburg and Christian 'yellow ferment'.

The contribution given by Dr. F. Dickens (Newcastle) formed the first bridge between the properties of the isolated systems and those systems organized in the tissue cells themselves. Directing attention to the tissue slice technique of Warburg for studying respiration, he considered that this proved in practice a fruitful compromise between the intact and macerated state, though minced tissue 'brei' where cell boundaries were destroyed was valuable for substances to which intact cells were impermeable. Tissue slices must be of appropriate thickness to allow of proper gas and substrate exchange. Under good conditions, slices of tissue in glucose solutions (Ringer bicarbonate or phosphate) will maintain remarkably constant rates of respiration, whereas with succinate as substrate this is not so; useful information as to the type of substance undergoing change can also be obtained by an estimation of the respiratory quotient, CO_2/O_2, as also by employing poisons which inhibit certain parts of the respiratory system. Dr. Dickens pointed out in a striking way the essential difference between the views of Szent-Györgyi and Krebs and Johnson as to the effect of the C_4 dicarboxylic acids. In the former case, catalysis is considered to be due to a series of reversible reactions, whereas in the latter the reactions proceed only in *one* direction, citric acid being supposed to form part of the reaction chain. In a discussion of this, Dr. H. A. Krebs (Sheffield) considered the dismutation of keto acids in bacteria and animal tissue, along the lines indicated by the following equations.

Anaerobic:

$$\begin{aligned}2\mathrm{COOH.CH_2CH_2.CO.COOH} + \mathrm{NH_3} = {} & \mathrm{COOH.CH_2CH_2CHNH_2.COOH} + {}\\ & \mathrm{COOH.CH_2CH.COOH} + \mathrm{CO_2} \qquad (4)\end{aligned}$$

Aerobic (with O_2 present):

$$\begin{aligned}\mathrm{COOH.CH_2CH_2.CHNH_2.COOH} + \mathrm{O} \rightarrow {} & \\ & \mathrm{COOH.CH_2CH_2.CO_2.COOH} + \mathrm{NH_3} \qquad (5)\end{aligned}$$

Glutamic acid can here act as a hydrogen carrier. This is a special modern example of the so-called Krebs' dismutations of α-keto acids in which carbon dioxide arises by decarboxylation of one molecule with simultaneous formation of the corresponding hydroxy acid from another molecule. In this paper we get the first introduction to one mechanism for the formation of carbon dioxide, probably a subsidiary one. In other cases in bacteria Dr. Krebs alluded to the use of succinic acid as a hydrogen carrier in the oxidation of acetic acid, part of the C_4 catalytic system being so employed. Dr. Mann's contribution should have dealt not only with the processes of H transfer involved in fermentation and respiration, but also with that of phosphate transfer; attention was directed to the coupling of oxidations with phosphorylations recently shown by Meyerhof, Needham and Lipmann, and to the fact that these reactions can be studied with advantage in tissue brei in which the fundamental cell organization has been destroyed.

With the contribution of Dr. J. H. Quastel (Cardiff), we turn to the reactions of the organized tissue respiration system (as found in the brain-slice) to the action of narcotics. Though it has been long considered that narcosis was due to diminished oxidations, it has only recently been emphasized by his school at Cardiff that narcotics have specific effects on tissue oxidizing systems; at low concentrations they greatly inhibit the oxidation by brain tissue of glucose, lactate and pyruvate, but not that of succinate or α-glycerophosphate, leaving cytochrome oxidase unaffected. Their inhibiting effects on brain respiration in the presence of glucose are definite at concentrations of narcotic which would be narcotizing *in vivo*; and with several narcotics the effects even on the tissue slice can be proved to be reversible. Though anaerobically there is no inhibition of pyruvate dehydrogenation by low concentrations of narcotics, in presence of oxygen there is marked inhibition; this may be related to the cocarboxylase (? diaphorase). These experiments were carried out with pyocyanin and ferricyanide. In a new point, they had found that suspensions of bacteria grown in media deficient in vitamin B_1, and suspended in pyruvate, showed a stronger inhibition of oxygen uptake by narcotics in absence of added vitamin B_1.

While Dr. Quastel's paper showed how tissue respiration could be altered by the action of drugs, Prof. Raper dealt with the equally fundamental and fresh point of how *in vivo* the cell controlled the rate of its respiration; How is the increased respiration consequent upon tissue activity regulated? He described experiments with slices of cat's submaxillary gland; the oxygen uptake is markedly stimulated with acetylcholine, this stimulation being inhibited by atropine. This important observation brings the whole question into relation with modern work upon the nervous system in its relation to these two substances, and forms a further valuable and much needed 'bridge' study. Acetylcholine did not affect anaerobic glycolysis though it slightly increased aerobic glycolysis. The effect of atropine suggests that acetylcholine does not act by increasing the available substrates, but rather by changing the availability of the catalysts concerned. (I think that this may have interesting relations to the address by Prof. E. K. Rideal upon surface film action.)

The question of carbon dioxide production through one of the main channels for this in tissue respiration was dealt with by Dr. S. Ochoa (Oxford), namely, the oxidation of pyruvic acid ($CH_3.CO.COOH$). There is a strong probability of a common path of carbohydrate breakdown to the pyruvic acid stage; the phosphorylated triose is oxidized anaerobically by dismutation, aerobically by giving up hydrogen to the cytochrome system through coenzyme I, flavoprotein and C_4 dicarboxylic acids. The phosphorylated oxidation product (phosphoglyceric acid) yields pyruvic acid which anaerobically is reduced to lactic acid, but aerobically is decarboxylated and oxidized; this gives, so far as is known, the main reaction in which carbon dioxide is liberated in the cell, and so forms the main source of respiratory carbon dioxide. It is catalysed, as has been shown for brain in Oxford, by cocarboxylase (vitamin B_1 pyrophosphate). (1 mol. cocarboxylase catalyses optimally the uptake of 1,500 mol. oxygen, producing 2,000 mol. carbon dioxide per min.) For complete oxidation inorganic phosphate, fumarate, adenylic acid and coenzyme I are required. During oxidative decarboxylation in brain brei, there appears to be an unstable C_2 intermediate which may appear as acetic acid in the absence of the rest of the enzyme system. There is some indication of a possible cycle of phosphorylation of pyruvate beyond this stage. Recent available evidence suggests that when dialysed brain preparations are incubated aerobically with fluoride, some inorganic phosphate disappears and a phosphate ester (not phosphopyruvate) accumulates in equivalent amounts only if pyruvate is present.

Striking a much more practical note, Dr. E. P. Poulton dealt with the question of local tissue anoxia in arterial disease and its treatment with oxygen, by the use of an oxygen tent. The improvement in the oxygen saturation of the tissues *in vivo* was of the greatest value in conditions such as rheumatism, a man being kept in the tent for days on end. That this is related to the oxidation changes in the tissues is shown by the fact that a high level of blood lactic acid, which would be caused by tissue anaerobiosis, is much reduced.

To summarize, it may be said that, with the exceptions mentioned in the opening address, the whole field of tissue respiration was well covered in summary form as it stands at the present time. As compared with twenty or even five years ago, the advance is truly marvellous and forms a fitting further chapter to the accurate knowledge of the carriage of oxygen and carbon dioxide in the blood, which has formed until now a main line of physiological research and thought upon respiration. From the purely chemical as distinct from the biochemical point of view, the strange medley of substances assembled by the cell to form the complex of catalytic systems necessary for the combustions in the tissue must always appear without logic and in strong contrast to the ordered schemes of pure organic chemistry. They will only receive a chemical meaning when we know more about the details of electron activation and exchange. Then we may be able to understand better why catalyses requiring low conditions of temperature and comparatively neutral reactions necessitate the compounds which we find. Until then, with biochemists, we can merely continue to record and wonder, and to enjoy the opportunities of intellectual interest to scientific workers of varied outlook which are presented by a study of this subject; actually it lies at the basis even of the material foundation of thought.

NOTE.—I am grateful to Dr. M. Dixon for access to the manuscript of his proposed address, and also to Dr. S. Ochoa for valuable notes of the proceedings at the meeting.

TWO BRITISH EXPEDITIONS TO UBEKENDT ISLAND, WEST GREENLAND

BY DR. H. I. DREVER, UNIVERSITY OF ST. ANDREWS

THE motive directly responsible for the organization of two British expeditions, the Cambridge West Greenland Expedition, 1938, and the St. Andrews University West Greenland Expedition, 1939, to West Greenland, was the inviting geological problems of Ubekendt Island (see Fig. 1) first encountered in 1937[1]. It was clear to me that apart from geological research, other work could also be undertaken in the same area, and that a party with a varied programme would offer, among other things, the further intrinsic interest of an 'expedition', the successful organization and conduction of which is in direct relation to the best working conditions and congenial co-operation. It is, in itself, a real problem in a non-scientific sphere.

Apart from the detailed geological examination of Ubekendt Island and similar work in parts of Upernivik Island, psychological, ethnological, archæological and botanical work was carried out, and high-altitude balloons flown in 1938[3] and, again in addition to geology, a small area in the south of Ubekendt Island was surveyed in 1939.

A detailed geological study of Ubekendt Island and also an extension of the work regionally in Nugssuaq south and in Svartenhuk north of the island had been planned in 1938. The rocks of these areas largely belong to the Tertiary Igneous Series. Geological work on Ubekendt Island was of first importance, but it was clear that the study of such an isolated area must necessarily be supplemented by more extended observations on a regional scale. This regional work was curtailed in favour of a Danish geological expedition under A. Rosenkrantz, although the Cambridge expedition was in no way restricted by the Greenland Commission for Scientific Research. Eventually it was thought fit to withdraw entirely British geological 'interests' in the regional aspect of the problems. Accordingly, in 1939 further work was confined to the areas examined in 1938, while a relatively large Danish expedition devoted its attention to the more extensive areas of Upper Cretaceous and Tertiary rocks (see Fig. 2 in black).

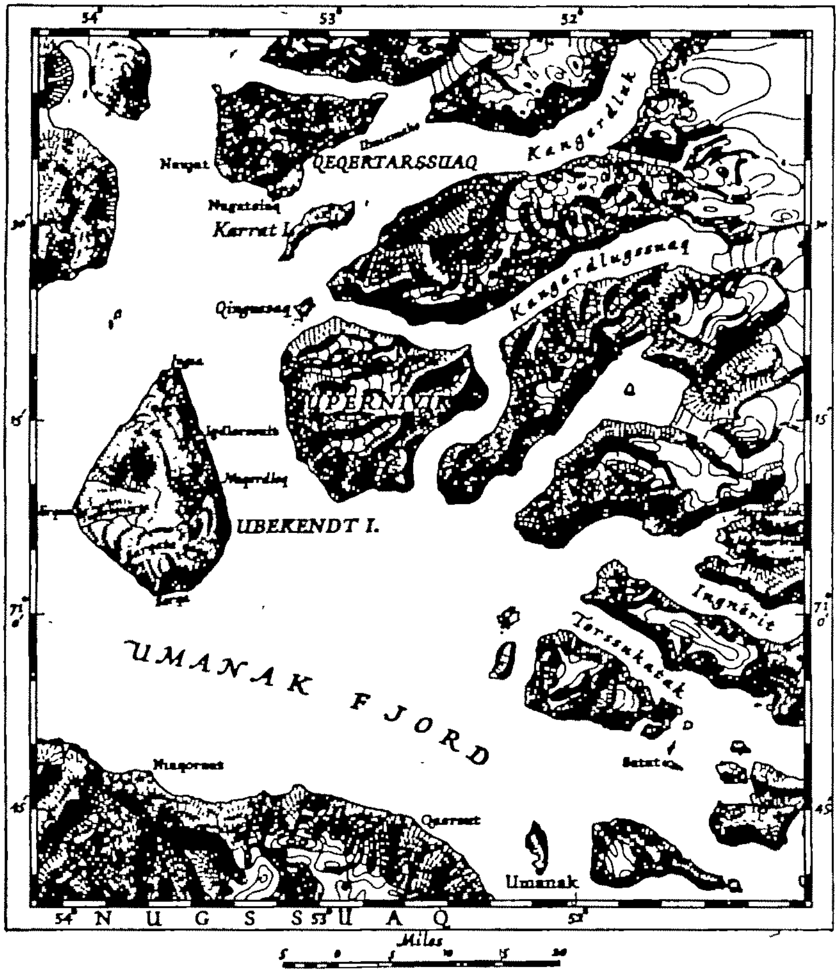


Fig. 1.

FROM THE *Geographical Journal*, 94, 388 (NOVEMBER 1939).

Recent research on the Scottish, Icelandic and East Greenland Tertiary igneous rocks has been of great petrological value, particularly that of H.M. Geological Survey. It was the purpose of the two expeditions to further our knowledge of this—the North Atlantic—Petrographical Province.

Ubekendt Island is composed essentially in the north of basic lavas and an intrusive complex of granite, gabbro and acid dykes in the south. Pyroclastic rocks are almost confined to the west coast near the remnant of a large volcanic neck. Cutting the lavas over the whole island are a large number of basic dykes with a local and variable rather than a constant regional trend. Representative collections have been made of all the rock types and the island has been geologically mapped.

Upernivik Island, on the other hand, is mainly Archæan orthogneiss, except in the south-west corner, where Cretaceous-Tertiary grits, sandstones and shales are faulted against the gneiss. A number of basic dykes and sheets cut the sediments, and there is one large sheet between 40 ft. and 60 ft. thick which has, in one place, a gabbroic centre. This area has been examined in some detail. Excursions were organized round the island, through the centre, up three of the western glaciers and the highest peak (6,893 ft.).

The psychological work was conducted in Igdlorssuit, the outpost settlement on the east coast of Ubekendt Island, and also in Umanak, the administrative centre of the district. The natives were the subject of experiments in social psychology, three individual tests were used and a study was made of group-contacts referring in particular to the relationships between Europeans and the Greenlanders. Some ethnological work was

SHORT REVIEWS

AGRICULTURE AND HORTICULTURE

Los Suelos de la Peninsula Luso-Ibérica (Soils of the Lusitano-Iberian Peninsula) (Spain and Portugal)
By Emilio H. del Villar. International edition in Spanish and English, the English Text (somewhat abridged) by Prof. G. W. Robinson. Pp. 416. (London: Thomas Murby and Co., Ltd., 1937.) 40*s*. net.

THE problem of devising a universally applicable system of soil classification calls for a wide knowledge of the soils found in different parts of the world as well as an intimate acquaintance with soils in the field. An attempt at devising such a system is made, by a pedologist with both these qualifications, in Prof. del Villar's work on the soils of Spain and Portugal.

Prof. del Villar groups soils according to their stratigraphy, composition and metabolism, choosing those factors which most directly affect vegetation. Seven main series are distinguished, including acid-humic, siallitic, calcareous and hydropedic groups. The calcareous series, which embraces rendzina, terra rossa and the peculiarly Spanish *calvero* soils, is perhaps the one which will prove of most interest to soil workers beyond Spain, since information on soil processes under Mediterranean conditions is still comparatively meagre.

The somewhat refreshingly unorthodox system of classification described appears to fit the soils of the Peninsula adequately and satisfactorily, but it is doubtful whether it could be generally applied to soil groups occurring elsewhere. Prof. del Villar's exposition of his system of classification includes many ideas and points of view which throw a new and constructive light on the difficulties of soil taxonomy, and the book is one which students of this comparatively undeveloped branch of pedology would do well to study.

The book is printed in Spanish, but it contains abridged English translations of each chapter, in which Prof. del Villar's views are clearly set forth. The translator, Prof. G. W. Robinson, in a prefatory note, adds tribute to the importance of the work, which, he says, must inevitably modify current ideas on soil genesis and classification.

The Soils of Palestine
Studies in Soil Formation and Land Utilization in the Mediterranean. By Dr. A. Reifenberg. Translated by Dr. C. L. Whittles. Pp. viii+131+8 plates. (London: Thomas Murby and Co., 1938.) 14*s*. net.

THIS authoritative account of soil conditions in Palestine, the outcome of thirteen years uninterrupted work at the Hebrew University, Jerusalem, is opportune. Part of the book is devoted to a description of soil formation within the framework of the Mediterranean type of weathering. The intense summer insolation destroys most of the soil organic matter and causes a predominantly upward movement of water containing silicic acid, ferric oxide and alumina. It is maintained that the colloidal silicic acid exerts a peptizing effect on the latter, and this accounts for their translocation in the presence of calcium during the formation of terra rossa on limestone. Terra rossa profiles are described, and theories of their formation with reference to rock weathering under different climatic conditions are discussed.

In dealing with the agricultural utilization of the soils it is emphasized that, since moisture is the main factor limiting crop production, irrigation is essential, and its success depends on the choice of water in which the concentration of salts is low enough to avoid injury to crops.

One of the most striking examples of the recent intensification of agriculture in Palestine is afforded by the citrus industry, the growth of which has revolutionized the whole of the country's agriculture. This progress is mainly due to the Zionist colonization, of which an account is given in the final chapter.

A. J. L. L.

Diseases of Bulbs
By W. C. Moore. (Ministry of Agriculture and Fisheries: Bulletin No. 117.) Pp. vi+176+20 plates. (London: H.M. Stationery Office, 1939.) 4*s*. net.

THE need for this book was great. Advisory mycologists, teachers of horticulture, and gardeners had to search for any knowledge about the diseases of bulbs among scattered journals in several languages. The almost dramatic expansion of the bulb industry in Great Britain, moreover, brought new problems in pathology, and it would be no exaggeration to say that disease occurrences had over-run mycological information.

Mr. Moore's volume is worthy of the occasion; it deals in great detail with fungal and virus parasites of all the commoner bulbs and corms of horticultural commerce, it illustrates the descriptions with fifty-eight excellent half-tone plates, and it considers several physiological irregularities akin more to ailments than to actual disease. The practical grower will find no difficulty in separating the descriptions of symptoms and control measures from the more technical matter, which the mycologist will find quite adequate to his purpose.

A list of 709 references to the world literature on bulb diseases should satisfy any further desire for study evinced by the reader, and the international scope of the volume makes it possible to provide information in advance about any maladies which are not yet widespread in Great Britain, but which may appear later. Among all the detailed excellence of the volume, the reader will probably feel the need for an alphabetical index of parasites. The book has a description of eelworm disease, which often occurs in close association with fungal maladies.

ARCHAEOLOGY AND ETHNOLOGY

The Maria Gonds of Bastar

By W. V. Grigson. Pp. xxi + 350 + 24 plates. (London: Oxford University Press, 1938.) 30s. net.

MR. GRIGSON'S anthropological investigations were undertaken largely owing to the suggestion of the late Sir Montague Butler; but his immediate objective in his contact with them was the remedy of certain grievances, more especially those caused by the application in a primitive State, of criminal, civil and revenue laws framed for British Indian districts some centuries more advanced. He found that it was by observation of their ceremonies and rituals and their daily occupations, as well as by inquiry into their family and social organization—in short through thorough-going anthropological investigation, by which science is the richer in this volume—that he was best able to arrive at their genuine and inmost opinions of, and attitude towards, the methods by which their affairs were being administered. Hence he was able, as Prof. Hutton says in his introduction, to introduce certain reforms.

Mr. Grigson's own comment on the relation of his anthropological investigation to the performance of his official duties is extremely illuminating. He points out how completely it refutes the arguments put forward by members of the Indian Legislative Assembly, in the debate on reserved and excluded areas which took place on February 18, 1936, when N. M. Joshi and M. S. Aney "heartily damned" all anthropologists as wanting to keep the primitive races in a state of barbarism as raw material for their science, and to add to their stock of knowledge. Mr. Grigson clinches the argument from his own experience by reference to the disastrous post-War attempt to force prohibition on Bhils, Gonds and Korku.

The scientific importance of this carefully detailed account of the relatively simple culture of the Marias is, however, underlined in an introduction contributed by Prof. Hutton. Dr. Ramesh Chandra Roy contributes an appendix on the physical characters of the Marias, in which he attributes evidence of a strain of brachycephaly in this predominantly dolichocephalic people to the influence of the central Asiatic or Alpine. Prof. Hutton, on the other hand, while admitting a certain subjectivity in his own view, inclines to see a Mongoloid strain, such as is present in the Assam tribes with whom he is most familiar. Turning to the cultural evidence, he supports his view in a very brief but masterly analysis of the cultural evidence.

Salween

By Ronald Kaulback. Pp. xi + 331 + 16 plates. (London: Hodder and Stoughton, Ltd., 1938.) 15s. net.

THE expedition to south-eastern Tibet which Mr. Ronald Kaulback describes in this volume started from Upper Burma in April 1935, and returned by way of Assam at the beginning of 1937. Of its twenty-two months duration, eighteen were spent within the borders of Tibet. The objective of the expedition was the exploration of the Nagong Chu valley, an affluent of the Brahmaputra, and the Brahmaputra–Salween watershed, as well as of so much of the course of the Salween as could be effected, with the upper waters of the Salween as the final goal. The project of exploring the hitherto unknown sources of the Salween had been formed by the author when a member of the Kingdon Ward expedition of 1933.

Unfortunately, this final piece of exploratory work had to be abandoned. Three months delay, while the further progress of the expedition was referred to Lhasa, made success too problematical. Not only was it questionable whether financial resources would be adequate—all cash for the needs of the duration of the expedition had to be carried—but also it was necessary to abandon the projected line of return through unexplored country, owing to local disturbances. The expedition returned by the Salween valley. Notwithstanding the disappointment of the author and his colleague, J. Hanbury-Tracy, the value of the survey work of the expedition in country, much of which had not been trodden previously by Europeans, was recognized by the award to Mr. Kaulback of the Murchison Grant of the Royal Geographical Society.

The author's graphic narrative makes light of the difficulties and discomforts of his journey, while throwing into relief the idiosyncrasies, individual and collective, of the people he encountered on his way. He was fortunate in obtaining an intimate view of several of the Tibetan seasonal festivals and of a remarkable prophetic ceremonial under possession. The photographic illustrations are of a high standard.

Philippine Pagans

The Autobiographies of Three Ifugaos. By R. F. Barton. Pp. xxi+271+24 plates. (London: George Routledge and Sons, Ltd., 1938.) 15*s.* net.

THE three Ifugao autobiographies comprised in this volume were collected in the course of an ethnographical investigation, which lasted for the greater part of 1937, in the island of Luzon. They attain a new standard in the attempt to eliminate the point of view of the white observer in cultural investigation. The subjects, two men and a woman, were told to record matters which they considered of most interest and importance in their lives. The narrative was, of course, taken down by the author, as the narrators were both pagan and illiterate. The result is significant in every sense. The topic which bulks largest is the pre-marital sexual relation, although for the woman, its special interest was its bearing on marriage and child-birth; but the influence of omens and the social ties of kinship and propinquity are also prominent in their influence on the course of events. Head-hunting figures repeatedly but it seems to be treated as of incidental, rather than of primary importance.

The institution which is pivotal in these narratives is that of the custom of the unmarried of both sexes sleeping in dormitories, either empty or occupied houses, apart from their families, and the consequent visiting of the females by the males, adolescent and mature. It is interesting to note that the author, as a result of the employment of this method of investigation and the intimate insight it has afforded him into native mentality, has had to reconsider an interpretation of the pre-marital sexual relation which he had based upon his experience of native institutions acquired in a residence among them over a period of seven years.

Archæology and Society

By Grahame Clark. Pp. xv+220+24 plates. (London: Methuen and Co., Ltd., 1939.) 7*s.* 6*d.* net.

ARCHÆOLOGY, no less than other branches of research, has profited from the increased popular interest in the results of scientific inquiry and their application to social ends which followed on the close of the War of 1914–18. If the practical bearing of archæological aims was less immediately apparent, this was counterbalanced by a number of spectacular discoveries, of which it will suffice to recall that of King Tutankhamen's tomb in Egypt and Sir Leonard Woolley's excavations at Ur. While it is beyond question that the study of archæology has profited much and gathered strength from this enhancement of popular interest, the constant stimulus of sensation needed to keep it alive has obvious dangers which may affect the quality of the investigation.

The present excellent review of the aims and methods of modern archæological investigation is designed to supply the public outside the ranks of the specialist with the basis of knowledge requisite to enable them to appreciate the bearing of archæological results achieved in the field, as well as the technical skill and the acumen in interpretation which contribute to the result. Thus in successive chapters he deals with discovery, in which it is explained how the archæologist knows where to dig, the preservation of early remains, depending upon the survival value of different materials, the methods and aims of the actual excavation, chronology, based upon stratigraphy and sequence, and interpretation, in that last tracing how the interest of modern archæological investigation no longer centres on the discovery of exceptional examples of the artistic products of the past, but in the reconstruction of the essential elements in the day-to-day life of the peoples of vanished civilizations.

In his final chapter on "Archæology and Society" Dr. Clark discusses certain aspects of archæological studies as a factor in modern life, and reviews briefly its relation to the development of nationalist sentiment in the smaller States which came into being after the War of 1914–18, as well as in Russia, Italy, Germany and Eire. While his readers will concur in his praise for what is being done in Eire, they will find his account of archæological activities in Russia, in which he relies on the evidence of Prof. A. M. Tallgren, more than disturbing, and probably feel that his view of the tendentious character of German theory under the Nazi regime is all too lenient.

BIOLOGY

British Purbeck Charophyta

By Prof. Thomas Maxwell Harris. Pp. ix+83+17 plates. (London: British Museum (Natural History), 1939.) 7*s.* 6*d.*

THE Charophyta have usually been regarded as a somewhat isolated group of Thallophyta, but the author of this monograph probably rightly regards them as a family of the Chlorophyceæ. Like some members of the Rhodophyceæ and Siphonales, they have left as records of their existence in past ages the calcareous clothing with which they invested their thallus. With the exception of the oospore membrane all the original plant substance has disappeared.

There are two important families in the group, the Characeæ and the Clavatoraceæ. By careful analysis of large numbers of fragmentary specimens which were extracted from the rock, the author has been able to distinguish some new and interesting types. A new genus, Charaxis, has been instituted for vegetative organs of fossil Charophyta, and one new species, *C. durlstonense*, is described. The most interesting and important part of the monograph consists of very complete descriptions of three species of the genus Clavator; *C. reidi* Groves, and two new species *C. grovesi* and *C. bradleyi*. A new genus, Perimneste, with one species, *P. horrida*, is of exceptional interest. These forms are all included in the Clavatoraceæ. There are careful detailed analyses of the construction of the thallus and the oogonia, and the descriptions are fully illustrated with photographs of a high order of excellence. Clear diagrammatic reconstructions are also given. Some parts of the descriptions might have been improved and clarified by the use of letters and indicator lines on some of the plate-figures. On p. 22 there is a paragraph on an exceptional cortical structure. It is not clear what is meant by opposite, and the reference to the figure in the plate (Pl. III, Fig. 8) does not help, for the figure appears to bear no relation to the written description. The technique employed in the investigation is a great advance on anything used before in work on the Charophyta, and in spite of the few obscurities to which reference has been made, the author has produced what is probably the best existing description of any collection of fossil Charophytes, and has provided us with a model of how such an investigation should be conducted.

J. WALTON.

Between Pacific Tides

An Account of the Habits and Habitats of some Five Hundred of the Common, Conspicuous Seashore Invertebrates of the Pacific Coast between Sitka, Alaska, and Northern Mexico. By Edward F. Ricketts and Jack Calvin. Pp. xxii + 320 + 46 plates. (Stanford University, Calif.: Stanford University Press; London: Oxford University Press, 1939.) 27*s*. net.

THIS delightful book, which was written chiefly for the layman interested in the seashore, deals with the littoral fauna from the ecological point of view. No scientific account of the animals is given, but most have been illustrated and their habits described. There are many beautiful photographs, though the recurring black background does not always make for clarity, and is, moreover, tiring to the eye. The sketches are variable, and one wonders whether the layman will understand a Pycnogonum or an Aplysia drawn upside down. The Latin names should have been more carefully revised; for example, *Reneira cineria* is incorrect both historically and philologically. The English reader cannot fail to note the similarity between the inhabitants of the various shore zones of California and of his own country. The species is rarely the same, but the genus often is. Even the commensals group themselves in the same way, and the description of the fat innkeeper, *Urechis caupo*, and its guests, written in the lively American style, should be read by all British marine zoologists. For more advanced readers the species are classified at the end of the volume, with references to the literature.

Animal Families and Where they Live

Written and illustrated by Arnrid Johnston. Pp. ix + 27 + 24 plates. (London: *Country Life*, Ltd., n.d.) 7*s*. 6*d*. net.

THIS attractively produced book is composed of a series of twenty-four plates (9 in. × 12 in.), each containing coloured sketches of animals grouped under such headings as 'egg-laying and pouched mammals', 'gnawing mammals', 'primates: New World monkeys', etc. Altogether 320 animals are featured, but the title of the book is misleading in that all the animals portrayed are mammals. Opposite each plate is a short description of each animal, one useful feature (often so unfortunately ignored) being the general measurements of the animal. Also on the opposite page is a world map showing distribution. This is of great value.

The book will make a very acceptable present for any animal lover, and if used during a visit to the Zoo will be a valuable aid in studying mammals especially in relation to each other.

Palæozoic Fishes

By J. A. Moy-Thomas. (Methuen's Monographs on Biological Subjects.) Pp. x + 150. (London: Methuen and Co., Ltd., 1939.) 5*s*. net.

IN view of the tremendous advances in our knowledge of the anatomy of fossil fishes during the past twenty years, the appearance of this little book should prove most opportune. A good deal of recent work, such as the classical researches of Stensiö on the Cephalaspids and Placoderms, has been published in journals not readily accessible to the average student or teacher, who will welcome the concise summary of these and equally important papers by other workers provided by Mr. Moy-Thomas. The recent work of Brough, Gross, Heintz, Kiaer, Nielsen, Säve-Söderbergh, Watson, Westoll, White and several other palæontologists, as well as that of Mr. Moy-Thomas himself, all finds a place in this volume of less than 150 pages, and the author is to be heartily congratulated upon the skill with which he has managed to reduce this mass of technical material to reasonable and readable limits. The book is at once competent, comprehensive, and concise, and may be confidently recommended to teachers and students of both zoology and geology. Evidence that it is right up to date is provided by the statement on p. 91 that the Coelacanths start in the Upper Devonian and continue to the present day, and a reference in the list of literature to the first account in Great Britain of the recent discovery in South Africa of the living Latimeria.

The many text-figures are admirably clear and well reproduced, and there is an excellent bibliography as well as an adequate index. The general production of the book well maintains the standard set by the earlier volumes of this series of pocket monographs on biological subjects.

Essays in Philosophical Biology

By William Morton Wheeler. Selected by Prof. G. H. Parker. Pp. xv + 261. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1939.) 12*s*. 6*d*. net.

THE late Prof. W. H. Wheeler began his career as a naturalist and later subjected his interests in living organisms to the disciplinary influence of scientific training. His philosophical outlook was conditioned not only by the naturalist's disciplined imagination arising out of a vast, first-hand acquaintance with animals and their behaviour, for he was, in addition, a great man of letters and a distinguished prose writer. His bibliography contains some 467 titles, most of them concerned with the classification, structure and behaviour of ants, but a considerable number deal with problems of embryology, evolution, parasitism and the social life of insects in general. These formal books have had great influence upon the world of biological thought, but his observations of insects in the field caused him to make incursions into psychology and sociology, and he became a master of the comparative branches of these sciences.

This book has been prepared in order to present in collated form some of Wheeler's philosophical beliefs which are distributed throughout the various scientific journals to which he contributed. The topics range from a discussion of instincts to a discourse about the dry-rot of academic biology, from the attractions of the field study of ants to biology and society. Reading them, one is reminded of the cogency of Prof. A. N. Whitehead's remarks about Wheeler when he described him as the only man he had ever known who would have been both worthy and able to sustain a conversation with Aristotle. Whilst the book stands primarily as a memorial to Wheeler, it represents a valuable addition to the world's scientific literature. T. H. H.

Outlaw of the Air

By Leslie Brown. Pp. x+246+8 plates. (London: Geoffrey Bles, 1939.) 8*s*. 6*d*. net.

THIS is an interesting account, told in the form of fiction, of the life of the great skua, a bird which is found only on the northern islands of Britain.

The author has evidently studied his subject with care, and he gives a convincing picture of the skuas at their island home. He describes them (as the reviewer has seen them do) standing on the backs of gannets flying at full speed, and forcing them to disgorge the herring they are carrying to their young; he has seen them attacking kittiwakes and even greater black-backed gulls. From a turf 'hide' he has watched the skua brooding its eggs and hatching its chicks, and a number of interesting photographs are a record of these hours of watching, although it is a pity that almost all the illustrations are over-enlarged, and thus suffer from a want of definition.

The book is thoroughly readable, and would make an acceptable Christmas present either to young folks or to their elders, and will keep the mind focused on the beauty and charm of Nature during the dark days through which the nation is passing. The book is very free from inaccurate observations, but surely a gannet (p. 93) does not "oar itself" cormorant-fashion below the surface when it fishes, but counts on the velocity of its aerial dive to enable it to approach, with closed wings, the fish beneath the surface; and when its momentum is exhausted re-emerges, still with closed wings, on the surface? Puffins (p. 52) do not arrive on their nesting islands off the Scottish coast so early as March—not indeed until the beginning of May as a rule. But these are minor criticisms, and the book deserves to be read by all who are interested in the birds of the coasts of the British Isles. S. G.

Physikochemische Grundlagen der histologischen Methodik

Von Prof. Dr. K. Zeiger. (Wissenschaftliche Forschungsberichte. Naturwissenschaftliche Reihe, herausgegeben von Dr. Raphael Ed. Liesegang, Band 48.) Pp. xi+204. (Dresden und Leipzig: Theodor Steinkopff, 1938.) 11.25 gold marks.

HISTOLOGICAL technique was once a mere rule-of-thumb affair, and there are some to whom it is so still! One stain gave red, another blue; one stained the nucleus, another cellulose; but how or why was no concern of the histologist so long as the result seemed good. But following Sir William Hardy's lead, men began to wonder how much of all their pretty preparations was artefact; and then came a growing desire to understand the rationale of fixing, staining and clearing in their chemical and physical relation to the colloids of the cell. So the histologist began to learn from the dyer the difference between an acid and a basic dye, and was some way along the road to skill and wisdom by the time he understood, for example, that a red blood-corpuscle was permeable to anions, and that eosin was, *ipso facto*, an appropriate dye.

Dr. Zeiger tells us in a couple of hundred pages the very things which the histologist now wants to know. He discusses hardening processes in relation to diffusion, permeability, shrinkage and so forth; staining as a chemical, an adsorptive, an electrostatic, or an electrocapillary phenomenon; Golgi's silver-method and its many variants and corollaries; intra-vital staining, including methods by which a single reagent may be made to differentiate various organs, tissues or cells; Ehrlich's methylene-blue, and its innumerable developments and consequences; *p*H and the ever-present need of keeping watch upon it (though without mentioning Bailey and Zirkle's work)—and many other useful and interesting things. D. W. T.

CHEMISTRY

Revision Notes in Inorganic Chemistry

To Higher School Certificate. By E. P. Wilson and F. W. Ambler. Pp. viii+240. (London: William Heinemann, Ltd., 1938.) 4*s*.

THE object of this book is to provide a revision course in inorganic chemistry up to higher certificate standard. The opening chapter deals with the classification of the elements, and subsequent chapters are devoted to the chemistry of the elements, arranged in the groups and sub-groups of Mendeléeff's table, though not in quite the same sequence. Questions from higher school certificate examination papers are given at the ends of the relevant chapters, and the book is provided with an adequate index.

In the reviewer's opinion the authors have considered too many unimportant compounds, and have not compared sufficiently the same compounds of different elements. In addition, the notes on 'non-certificate' elements are too brief to be of value to university students and should have been omitted. A. C. C.

The Essentials of Volumetric Analysis

By John Lambert, in conjunction with A. Holderness and Dr. F. Sherwood Taylor. Pp. vii+92. (London: William Heinemann, Ltd., 1938.) 2*s*. 6*d*.

THIS book provides a suitable course in volumetric analysis for the higher school certificate examinations. Thus an account is given of the preparation and use of standard solutions of acids, alkalis, potassium permanganate and dichromate, iodine, thiosulphate, and silver nitrate in neutral and acid solution. A concise and clear explanation is also given of the theory of indicators, including adsorption indicators. A useful feature of the book, especially from the point of view of scholarship candidates, is the list of practical problems at the ends of the chapters. Atomic weights, tables of logarithms and an index are given at the end of the book.

A. C. C.

Ergebnisse der Vitamin- und Hormonforschung

Herausgegeben von E. Mellanby und L. Ruzicka. Band 2. Pp. xv+520. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1939.) 34 gold marks.

THIS survey of current knowledge in selected fields of hormone and vitamin research, of which the first volume was reviewed in NATURE, **143**, 659 (1939), maintains the cosmopolitan aspect to which we then directed attention. Four articles are in English, all from England: four are in German, one from the United States, one from Switzerland and two from Germany: three are in French, two from France and one from the Argentine.

The authoritative nature of the various contributions leaps to the eye. Profs. Haworth and Hirst write on the chemistry of ascorbic acid and its analogues: Prof. Bertrand contributes an essay on the physiological significance of manganese and other 'trace' elements: Dr. Hans Brockmann discusses the chemistry of the antirachitic vitamins, and Prof. Rominger their physiology and pathology. Prof. J. W. Cook describes the chemical and biological properties of the carcinogenic substances, while an analysis by Prof. Lacassagne of the connexion between cancer and the sex hormones is reassuring in its conclusions. Prof. Houssay and Dr. Deulofeu have some forty-five pages on the chemistry and secretion of insulin. Prof. Karrer appropriately reviews the chemistry of the flavins. Articles by Dr. Haagen-Smit on the plant growth-hormones and by Prof. Korenchevsky on the bisexual (and other) effects of pure male hormones on females make up the eleven sections of the book.

Thus it will be seen that, like its predecessor, this volume ranges from chemistry to clinical medicine, with adequate attention to the intermediate co-sciences of bio-chemistry, physiology, therapeutics and pathology. A change of editorship is to be observed in the replacement of Prof. W. Stepp by Sir Edward Mellanby; one can only speculate as to where and when subsequent volumes will be published and hope that these "Ergebnisse" will not have to be included among the war victims.

A. L. BACHARACH.

ENGINEERING

Les gisements de pétrole

Géologie, statistique, économie. Par Prof. Georges Macovei. Pp. vii+502. (Paris: Masson et Cie., 1938.) 120 francs.

M. GEORGES MACOVEI is well qualified to write a text-book on petroleum since he brings to the task twenty years of experience as a lecturer at the Polytechnic School in Bucharest and thirty years of practical experience of the Carpathian deposits. He has not hesitated to consult the works of already established authorities on the subject in England, France, Germany, the United States and elsewhere, but in addition has embraced many of the precepts of his fellow countrymen, in particular those of M. Louis Mrazec, of whom he is an admiring disciple. Those who are looking for originality may therefore be disappointed, certainly in regard to text figures, only about twenty of which are entirely new out of a total of two hundred and twenty-two.

The first part of the book follows conventional procedure in petroleum text-books, and the accepted principles of petroleum origin, constitution, production, etc., are unfolded along familiar lines. The author relieves monotonous sequences of facts wherever possible by reference to practical examples he has encountered in the field; but, being most familiar with the Rumanian oilfields, he tends perhaps to over-emphasize their importance in relation to oil deposits in other parts of the world.

The second half of the book is devoted to a description of the known deposits of petroleum throughout the world. No attempt is of course made to give complete details of all deposits, but indications are in each case given of extent, yield and potential reserves.

Few writers of text-books on petroleum can withstand the temptation to estimate world resources of this product. M. Macovei succumbs in the last chapter and quotes some astonishing figures. From statistics gleaned from a variety of sources he estimates that world reserves at the beginning of 1938 were 5,173 million tons. He then proceeds to calculate on a basis of 1937 withdrawals that petroleum will be exhausted in Mexico in five years, in the United States in twelve years and in Rumania in thirteen. Even Iraq, the supplies of which are expected to outlast those of the rest of the world, will have exhausted her reserves in less than a hundred years according to this author's approximations.

Petroleum Production Engineering

Oil Field Exploitation. By Prof. Lester Charles Uren. Second edition. Pp. ix+756. (New York and London: McGraw-Hill Book Co., Inc., 1939.) 36*s*.

THE fact that Prof. Uren has had to expand the first edition of this work, which he wrote fifteen years ago, into two volumes and approximately twice as many pages is yet another indication of the steadily accumulating mass of technical knowledge now available to the petroleum industry. The work is of necessity still academic in its bias, but, if thoroughly digested by students during their university course, must provide an excellent preliminary to practical experience in the field. It may also prove useful as a book of reference for those who have already had practical experience in the industry and yet desire to consolidate their knowledge in terms of academic principles.

Statistical Year-Book of the World Power Conference

No. 3: Data on Resources and Annual Statistics for 1935 and 1936. Edited, with an Introduction and Explanatory Text, by Frederick Brown. Pp. 138. (London: World Power Conference, 1938.) 20*s*. net.

THE same principles are followed in this third Year-Book as in No. 1 (1936) and No. 2 (1937), the ultimate aim being to give *comparable* statistics of world power resources. Two noteworthy advances have, however, been incorporated in this volume, quite apart from progress made towards publication of complete statistics for the whole world. For the first time a table is included at the beginning of the volume showing the area and population of most of the countries from which statistics have been obtained. Also there is clear indication that the several countries have made a greater effort to return statistics in conformity with definitions adopted by the World Power Conference.

MATHEMATICS

Tables for Converting Rectangular to Polar Co-ordinates

By Dr. J. C. P. Miller. Pp. 16. (London: The Scientific Computing Service, Ltd., 1939.) 2*s*.

DR. J. C. P. MILLER has compiled these tables to facilitate the conversion of rectangular to polar co-ordinates, and after several years of experiment he is convinced that they afford the maximum efficiency. Acknowledgment is made of the advice and assistance of Dr. L. J. Comrie both in the computation and publication of the tables. A full description of the method of application with a computing machine and also with a slide rule is given, and, generally speaking, only one set-up of the machine or rule is necessary. Where maximum accuracy is essential, two settings are sometimes required with the slide rule, and examples are given which show the various degrees of accuracy that arise with one or two settings. The tables have already been extensively used in manuscript form for the transformation of harmonic constants a and b, obtained by harmonic analysis, to amplitude c and phase angle ϵ, in accordance with the relation

$$c \sin(nt + \epsilon) = a \sin nt + b \cos nt.$$

As further applications may be mentioned the evaluation of the magnitude and direction of a vector from rectangular components, and the conversion of complex numbers from the form $x + iy$ to the form $re^{i\theta}$.

The tables will be very useful in various branches of applied science.

Trigonometry, with Tables

By Prof. Howard K. Hughes and Glen T. Miller. Pp. viii+190+79. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1938.) 7*s*. 6*d*. net.

TEACHERS of elementary trigonometry may discuss the order in which to introduce the tangent, the cosine, and the sine, and there are substantial and interesting arguments in favour of each as the first to be studied, but there has been general agreement for many years that in a first course the tangent and the sine or cosine should be introduced separately, whether the actual definitions are in terms of right-angled triangles or of co-ordinates. It is typical of the teaching of Messrs. Hughes and Miller that they throw the six circular functions simultaneously at the pupil's head at the very beginning, and this implies, on the kindest interpretation, that the subject has been deferred far beyond the age at which the elements of it can profitably be studied. We need scarcely give other reasons for doubting whether this text-book is suitable for the use for which it is intended. On principle, the inclusion of a chapter on spherical trigonometry is to be commended, and an attractive set of tables is paged independently at the end of the volume. The printing and production are exceptionally good. E. H. N.

MISCELLANY

Bibliographie de Maurice Maeterlinck

Littérature, science, philosophie. Par Maurice Lecat. Pp. 208. (Bruxelles: Libr. Castaigne, 1939.) 35 francs.

M. MAURICE LECAT, the relentless and indefatigable critic of the "Belgian Shakespeare", has issued separately the bibliography which forms part of his work entitled "Maeterlinckisme", of which the first volume was published in 1937 and the third is to appear shortly. The bibliography consists of two parts devoted respectively to works by or about Maeterlinck. Appended is a bibliography of the publications of M. Lecat, who is a doctor in mathematical and physical sciences, a mining engineer, and a laureate of the Académie des Sciences.

The Psychology of Physics

By Blamey Stevens. Pp. xvi+282. (Manchester: Sherratt and Hughes; New York: G. E. Stechert and Co., 1939.) 7*s*. 6*d*. net.

NEITHER the psychology nor the physics of this book is of the conventional type. In a previous book, "The Identity Theory" (1936), Mr. Blamey Stevens put forward views which are now presented in a simpler form. To begin with, he suggests that space and time have no objective reality, and are merely two different subjective or *perceptual* aspects of an identical thing, which may be called substance. On bases such as these, a complete perceptual theory of physics is built up, rejecting many of the accepted laws, but replacing them by others which, it is claimed, are in accordance with empirical facts.

Ethics in Modern Art

By Marjorie Bowen. (Conway Memorial Lecture delivered at Conway Hall, Red Lion Square, W.C.1, on April 19, 1939.) Pp. x+50. (London: Watts and Co., Ltd., 1939.) Paper, 1*s*. net; cloth, 2*s*. net.

THIS lecture must have been a stimulating and provocative discourse, for surely many hearers must have itched to refute and debate its many inconsistencies. For example, while apparently condemning 'escape' stories, Miss Bowen praises the effect of music and poetry in taking us away from our petty troubles, trivial fears and everyday worries—surely an appeal for 'escape'.

The reviewer feels that, while admitting the complete freedom of modern art, plastic or otherwise, Miss Bowen would seem to consider that this freedom should be one-sided, and that the percipient of art should support monetarily that which to him is repulsive.

For art to have an ethical value, we must surely have some *rapport* between artist and percipient. If the artist can use his keener vision in such a way as to reinforce that of the percipient, then we admit his power, ethical or the reverse, in influencing his fellows. But the public liking for purely objective stories and pictures seems to show that the artist of the more intense school has lost rapport with the normal man, who dismisses the detailed character study and self-representation school as long-winded and faintly repulsive. The many works of this nature are meat for the few, and the rest of the world will ignore them.

Miss Bowen pleads for æsthetics in education: "Children could be taught æsthetics, to understand and to value the work of the artist. . . . Children should see, hear and read the ugly, the trivial, the silly as little as possible". Surely this was the system of the Victorians, used according to their lights, which produced the intolerance of novelty so deplored by Miss Bowen. On the same page we are told that the child is not to study great poets, nor to have fine music offered it, nor have great pictures analysed for it. As æsthetics are to be studied, and the great and the trivial alike are to be avoided, we have here the apotheosis of mediocrity.

There is much in the lecture with which all must agree, and the rest of it, being controversial, arouses the more interest.

PSYCHOLOGY

Incentives and Contentment

A Study made in a British Factory. By Patricia Hall and H. W. Locke. Pp. xii+190. (London: Sir Isaac Pitman and Sons, Ltd., 1938.) 2*s*. 6*d*. net.

THIS book describes the results of some research work carried out in a pioneer factory, which has attempted to put into practice a system of democratic government. The object was to discover those factors involved in the production of good work allied with contentment.

An analysis was made of the factors around which satisfaction and discontent centre; for example, remuneration, promotion, suitability for the job, the value of creative work, conditions inside and outside the working situation. The many motives that might play a part in actuating human endeavour were also considered. Lastly, the important subject of leadership, both managerial and in the workroom, was discussed, and this led on to the subject of the 'difficult' employee.

There is an interesting reference to the psychological department, which endeavours by vocational studies to reduce the number of maladjusted workers, by taking into account such factors as temperament, ability, interests.

This research has shown quite clearly that if incentives are to be effective, and contentment real, they must be contingent upon the satisfaction of those abiding instincts and desires that are present in every man and woman. It also emphasizes the importance of selecting for managerial posts people who have the power of leadership and can enter sympathetically into the point of view of their subordinates.

The book is one to be recommended to all students of industrial problems.

Fifty Years of Psychical Research

A Critical Survey. By Harry Price. Pp. xii+383+15 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1939.) 10*s*. 6*d*. net.

ALTHOUGH this work purports to be a critical survey of the work undertaken by psychical research workers during the last fifty years, and even to be a continuation of the late Mr. Frank Podmore's history of modern spiritualism, it is, if the truth be told, nothing of the kind. It consists of a miscellaneous collection of material, written in a popular style and forming more than anything else a kind of abstract or digest of some of the more sensational cases of recent times. There is no attempt to present the subject-matter in historical sequence with due regard and appreciation of the factors underlying the changes in technique and experimentation during the course of time, and moreover a good deal of space is given to accounts of cases of no conceivable scientific or even historical importance, whilst others of considerable psychological value are omitted altogether.

Regarded as a well-documented and popular guide to the less serious side of psychical research during the last fifty years, this work will doubtless fulfil a useful purpose; but it cannot be claimed that it is in any sense a well-balanced, historical or critical account of a period in psychical research when much has been done and foundations laid for a better and more scientific approach to the problems in dispute. In order to meet this claim, what is required is a long and detailed account of the work accomplished, together with a running commentary dealing with the developmental history of experimental methods and a careful evaluation of the results obtained, with suggestions for improving both technique and constructive criticism.

E. J. D.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST. ALBANS.

(*Continued from page* 1074)

undertaken in Igdlorssuit. An examination of five ancient habitation sites was made on Ubekendt Island, and two of these, on the south and south-west coasts, were very productive of material. In the more easterly of the two sites, two houses were excavated and showed traces of both Eskimo and European cultures. The latter is of eighteenth century origin and the former up to two centuries earlier.

A collection of 405 plant specimens was obtained for the British Museum in 1938, chiefly from Ubekendt Island.

In continuation in 1938 of the work by Carmichael and Dymond[3], a number of pilot balloon flights were made. Evidence was obtained confirming the work of the previous year, very small wind velocity being again noted in the stratosphere at heights above 15 km. and a velocity maximum about 9 km. in the troposphere. The single theodolite (R.A.F. type) method was employed on the assumption that the balloons rose at constant rate. The same type of balloon was used as in 1937.

Longitude and latitude observations made at Igdlorssuit by means of a Watts 3½-inch micrometer theodolite indicate that the position of Ubekendt Island is correctly shown in the existing charts and maps. The topography of this island and also that of Upernivik is very inadequately and sometimes wrongly represented. A detailed plane-table triangulation on the scale of 1 : 50,000 was made of a small area embodying the most interesting geological features on the southern half of Ubekendt. Observations taken during excursions on Upernivik will amplify the topography and correct some errors.

Finally, it is thought desirable, on the whole, that work along similar lines should be encouraged, and, with the permission of the Greenland Administration, continued.

OBITUARIES

Prof. W. Lindgren

PROF. WALDEMAR LINDGREN, deeply respected by all mining geologists, died at Brookline, Massachusetts, on November 3 at the age of seventy-nine. He was born at Kalmar in Sweden, and, after a general education in his own country, qualified for the diploma of mining engineer at the well-known *Bergakademie* of Freiberg in Saxony. In 1884 he emigrated to the United States, and soon after was appointed an assistant on the United States Geological Survey, where he passed through successive grades to be chief geologist in 1911.

Lindgren's field work was mostly done on the mining fields of the western States, in Arizona, California, Colorado, Idaho, Oregon, and Utah, his results being described in a series of remarkable memoirs which were characterized by carefully detailed records of the geology and mineralogy of the ore deposits, supplemented always with cautiously restrained excursions into the field of theory regarding their origin. On the data recorded in these earlier papers was built up the theory of 'secondary enrichment', especially of sulphide-ore deposits; for he noticed that the solutions formed by meteoric waters near the outcrops of the lodes passed down along the ore-bodies, and became deoxidized at greater depths preparatory to re-precipitation of the metals as sulphides by reaction with the primary ores at lower depths in the deposits. The theoretical aspects of this question and their variations due to previous changes in the physiography of the areas were afterwards discussed by Lindgren in various papers published in *Economic Geology*.

At a later stage in his long career of activity, and based partly on a study of the tin deposits in Bolivia and elsewhere, Lindgren formulated the principles of metasomatism as a process in the formation of ore-deposits. This subject he analysed in all its theoretical aspects in his presidential address to the Geological Society of America in 1925.

Occasional by-products of his main line of work appeared as descriptions of new mineral species and new occurrences of known forms. He was the first to recognize analcite as a primary mineral in igneous rocks, and this led to the necessity of re-examining the colourless, isotropic substances previously assumed to be residual glass in many basalts.

In 1912 Lindgren was appointed professor of economic geology at the Massachusetts Institute of Technology, and in the following year he published the first edition of his comprehensive treatise on "Mineral Deposits". In 1933 he retired from his chair after twenty-one years of distinguished service; and Prof. Palache, the eminent mineralogist at Harvard, two years later took the opportunity of giving the name lindgrenite to a new natural molybdate of copper, in the year in which Lindgren received also the honorary D.Sc. from Harvard. At "Technology", as the Institute is locally known, Lindgren's name is deeply respected, and is there preserved as the name given to the library of mining and geology. In 1933 he was elected president of the International Geological Congress, and two years ago the Geological Society of London conferred on him the highest honour at its disposal, the Wollaston medal, which has the peculiar interest of being struck in palladium, the relatively rare metal first isolated in 1802 by W. H. Wollaston.

Lindgren's massive record of facts about mineral deposits has been and will be extended by others; but it is unlikely that his theoretical deductions will ever undergo serious change, for he was too wise to stray beyond the deductions immediately justified by the facts, and he knew far too much about his subject to regard any present theory of ore-deposits to be complete to the exclusion of all others.

T. H. HOLLAND.

Prof. W. P. Lombard

THE death of Warren Plimpton Lombard at the age of eighty-four years removes one of the last direct links between the laboratory of Carl Ludwig and experimental physiology in the United States—a link with which American physiologists, like those of Britain, have always been proud. Born on May 29, 1855, the son of Israel Lombard by his wife, Mary Ann Plimpton, he was descended on both sides of his family from Puritan stock which had emigrated to the American continent early in the seventeenth century. He was born and spent his boyhood in West Newton, Massachusetts, and obtained his preparatory education in the public schools of that town. He received his baccalaureate degree from Harvard in 1878; and also an M.D., Harvard, in 1881.

On the advice of Henry Pickering Bowditch, who was a pupil of Ludwig as well as the first experimental physiologist of Harvard, Lombard went to Leipzig in 1881 to spend three years in the stimulating and liberal atmosphere of Carl Ludwig's laboratory. There he became interested in muscular contraction, in spinal reflexes and in the various recording techniques which Ludwig had devised and of which he was an accomplished master. His first paper, published from the Leipzig laboratory, dealt with the sequence of contractions of various muscles of the hind limb of the frog under reflex stimulation (*Arch. Anat. u. Physiol.*, 408; 1885). He designed elaborate recording myographs which made possible simultaneous records of as many as twenty muscles attached simultaneously to the lever system.

Lombard was one of the first after Descartes to consider the problem of reciprocal innervation of antagonistic muscles. Later he studied the knee-jerk, vasomotor reflexes, skin temperature and its control; and his successor, Robert Gesell, states that much of Lombard's time during his early years was devoted to the study of the mechanics of two-joint muscles (see *Amer. J. Physiol.*, 20, 1; 1907). "The fact that a two-joint muscle can make use of the tendon action of another two-joint muscle on the opposite side of the leg accounts for the paradox that a two-joint muscle, when in a position to have a stronger extensor than flexor leverage, may extend a joint of which it is a flexor". He was likewise interested in respiration and worked out a balance sufficiently sensitive to record the minute changes in weight incident to the fluid loss which accompanied each expiration. His technique for observing capillary circulation in man has been almost universally adopted in the many subsequent studies carried out in this field. As a teacher he followed Ludwig in being an ardent exponent of 'practical' laboratory instruction, and few better laboratory guides have ever been written than his "Directions for Laboratory Work in Physiology for the use of Medical Students (2nd ed. 1914).

On returning to the United States from Europe, Lombard became an assistant in physiology at the College of Physicians and Surgeons in New York City. Thereafter he went back to Europe for several years and on reaching America again in 1889 he accepted the appointment of assistant professor in physiology at Clark University in Worcester, Massachusetts. In the same year, William Howell took the chair of physiology at Michigan as successor to Henry Sewall, whose health had forced him to abandon the inclement weather of Michigan for the clearer and warmer climate of Colorado. Howell was called to Johns Hopkins in 1892 and Lombard was then asked to fill the chair of physiology at the University of Michigan, where he remained until his wife's death in 1923, at which time he retired.

Lombard was a warm and friendly person, who had wide interests apart from science, and in the years between his retirement and his death he devoted himself to drawing, water-colour painting and etching. He spent his summers at Monhegan, Maine, and his friends paid tribute each year to his increasing artistic skill. Shortly before his death, he read a paper to a scientific club in Michigan in which he characterized himself in the following terms: "I have always been an optimist and I cannot claim to have ever been religious. I have thoroughly enjoyed life and feel that the finest one can do is to bring pleasures into the lives of others. In this I find a worthy reason for living and shall be glad to live as long as I can enjoy life and help others to do so."

J. F. FULTON.

WE regret to announce the following deaths:

Mr. George Eumorfopoulos, the well-known collector of Chinese porcelain and other examples of Oriental art, on December 19, aged seventy-six years.

Prof. Eduard Fischer, professor of botany in the University of Bern from 1897 until 1933.

Senatore Prince Ginori Conti, a well-known Italian industrial chemist, on December 3.

Prof. A. J. Hopkins, emeritus professor of chemistry in Amherst College, known for his work on the early history of science, on November 10, aged seventy-five years.

NEWS AND VIEWS

Scientific Research and Technical Development

AN Advisory Council on Scientific Research and Technical Development has been set up by the Minister of Supply to advise him on scientific and technical problems. The main functions of the Council will be to ensure that the work of the Directorate of Scientific Research is carried out with due regard to recent advances in scientific knowledge, to introduce new fields of research and development, and to make recommendations regarding the most effective use of scientific personnel. The chairman of the Council is Lord Cadman, emeritus professor of mining and petroleum technology in the University of Birmingham, chairman of the Anglo-Iranian Oil Co., Ltd. and of the Iraq Petroleum Co., Ltd. The Admiralty, Air Ministry, and Ministry of Home Security are also represented on the Council, of which the joint secretaries are Mr. E. T. Paris and Mr. F. Roffey, Ministry of Supply, Adelphi, W.C.2.

THE Council is constituted as follows: Prof. E. N. da C. Andrade, professor of physics, University College, London; Dr. E. V. Appleton, secretary, Department of Scientific and Industrial Research; Sir Joseph Barcroft, formerly professor of physiology, University of Cambridge; Prof. W. L. Bragg, Cavendish professor of physics, University of Cambridge; Major-General E. M. C. Clarke, director of artillery (military adviser), Ministry of Supply; Prof. J. D. Cockcroft, professor of natural philosophy, University of Cambridge; Major-General A. E. Davidson, controller of mechanization development (military adviser), Ministry of Supply; Dr. H. J. Gough, director of scientific research, Ministry of Supply; Dr. H. L. Guy, chief engineer, Mechanical Engineering Department, Metropolitan-Vickers Electrical Co., Ltd.; Sir Harold Hartley, vice-president and director of research, L.M.S. Railway, and chairman of the Fuel Research Board; Prof. I. M. Heilbron, professor of organic chemistry, University of London; Prof. A. V. Hill, secretary, Royal Society, and Foulerton research professor (physiology); Prof. R. S. Hutton, professor of metallurgy, University of Cambridge; Sir Robert Robertson, director of the Salters' Institute of Industrial Chemistry, formerly Government chemist; Sir Robert Robinson, professor of chemistry, University of Oxford; Mr. J. Rogers, deputy director-general of explosives, Ministry of Supply; Sir Frank Smith, director of instrument production, Ministry of Supply, director of research, Anglo-Iranian Oil Co.; Prof. R. V. Southwell, professor of engineering, University of Oxford; Prof. G. I. Taylor, Yarrow research professor of the Royal Society (engineering); Sir Maurice Taylor, senior military adviser, Ministry of Supply; Sir Henry Tizard, rector of Imperial College of Science, chairman, Aeronautical Research Committee.

Early Man and his Forerunners

IN the two years 1937–39 a series of researches carried out by P. Teilhard de Chardin, Prof. Franz Weidenreich and their fellow-workers of the Cenozoic Research Laboratory of the Geological Survey of China, papers on which have only just reached Great Britain (see NATURE, December 23, p. 1054 and December 30, p. 1097) has made a notable contribution to anthropological study, not merely in so far as it deals with early man in China, but also in its bearing upon fundamental problems of the development of the human stock and the origin and distribution of its varieties. How far Teilhard de Chardin's suggested need for a revision of Tertiary and Quaternary classification in geology and palæontology will be accepted as of general application may remain in abeyance for the moment; but his brilliant synthetic study of recent geological and palæontological discovery provides a new diagnosis—in China at least—for the much-debated division between Pliocene and Pleistocene in the form of the definite break, almost catastrophic in its proportions, in fauna and physiographic conditions between the Nihowan and Choukoutien phases of the so-called Sanmenian, which is followed by the appearance of man, who in some sort, it may be suggested, now might be regarded as a characteristic fossil.

THE work of Prof. Weidenreich, more especially with the supplement of the cultural study of the contents of the palæolithic cave at Choukoutien, by W. C. Pei, offers too many points of interest for detailed comment here. One matter of special moment is the inference he draws that the important body of knowledge which has been derived from the specimens of Sinanthropus calls for "a radical transformation of our conceptions of the problem of mankind", and he then proceeds to the significant conclusion that while human development has been orthogenetic, it has also been polycentric, certain consequences following logically upon this as affecting the mode of that development, in which Lamarckian and Darwinian conceptions are set aside as unimportant in favour of an evolutionary progressive development of the type. At the same time, his remarkable diagnosis of three racial types—Melanesian, Eskimoid and Mongoloid—in a single and small palæolithic population at so early a date is scarcely less significant for the further development of racial theory at large. Mr. Pei's cultural study of this same palæolithic population affords a view of its technological capacity which is little less than surprising. This is also, be it noted, the first site in China on which cultural material of palæolithic age and human skeletal remains have been found in association.

Universities and Government Grants

IT is generally known the Government grants to the universities of Great Britain have been stabilized for a limited period from the beginning of the War. As that time approaches its end, the Government and the University Grants Committee will be faced with a difficult task. The incessant call for economy at this time of stress must be heeded. No sum that can be saved, however small it may be, is negligible in the present circumstances; indeed it may be in the multitude of minor economies that the best hope lies. Nevertheless, in the matter of the universities, great caution and careful scrutiny will be necessary. Any move which curtails the efficiency of the universities in the discharge of their duties would be sharply criticized. It will readily be granted that the undergraduate population of the universities has decreased substantially, and national service has also claimed a varying proportion of the teaching and supervisory staffs. Teaching and research must, however, still go on. Apart from present needs, there is the future to consider. When the time comes for reconstruction, the universities must be ready to expand rapidly and to play their part in building up the new order. This they can do only if they retain their efficiency throughout the days of war-time activity. The task of those in authority will be to satisfy present needs and also to enable the universities to meet their obligations to the future.

British Social Hygiene Council

IT has been found impossible to continue meetings of the full Educational Advisory Board of the British Social Hygiene Council during the War. A representative Emergency Committee has been formed, however, and held its first meeting on December 19 at Tavistock House, London, W.C.1. It was decided that the long-term policy of stimulating the development of biological education should be maintained so far as is possible. The possibilities of educational activities are to be explored on a regional basis; particular attention is to be directed towards providing short courses of lectures and talks for youth leaders, adolescents and men and women in the military forces. The development of biological education in the Colonies is being continued and negotiations for the production of text-books of biology for use in schools in East Africa should soon be completed. Tentative inquiries are also being made to determine the possibilities of holding a Summer School for teachers, if circumstances permit.

Dendrochronology in the Eastern United States

THE dream of the archæologist, for whom from the nature of his material an absolute chronology is rarely available, has been the attainment of a system of dating which should be universally valid; but diversity of conditions, as a rule, precludes anything approaching certainty when attempts are made to apply any given method of time measurement outside a more or less restricted area. For this reason much interest is attached to attempts which are being made to extend the tree-ring method of dating outside the south-western United States, where it has been applied with conspicuous success to the dating of Pueblo remains and structures. The first successful observations in the eastern United States are recorded by Prof. Charles J. Lyon, of Dartmouth College (*Science*, **90**, 419; Nov. 3, 1939), who has compared the rings of virgin white pine felled by a hurricane in September 1938 at Wolfeboro, N.H., with buried logs of the same species uncovered in an excavation at the site of an ancient bridge abutment nearby. The skeleton plot method of Douglass gave the date of 1806 for the last ring formed in the trees used to build the bridge, a result said to be "very reasonable in the light of Wolfeboro history". Further, from North Sutton, N.H., thirty-nine miles south of this bridge, a record of white pine was obtained for a 260-year period, establishing a link with the buried logs in a 128-year overlap between the outer rings of the latter and the inner rings of the Sutton trees. Although not sufficient for a standard scale, yet this marks a beginning in the formulation of an efficient instrument for the eastern archæologist; but it is noted that the identification in detail is less perfect than in the south-west. Apart from the cross-check, however, the rings agreed with a number of entries of drought in a diary.

History of Intensive Cultivation

AN interesting historical review of progress in the production of early vegetables by methods of intensive cultivation has recently been issued by R. J. G. Hopp (*J. Roy. Hort. Soc.*, **64**, Pt. 2; Nov. 1939). The first record of forcing plants appears to be in the time of the emperor Tiberius, when cucumbers were grown in boxes of dung and sheltered during cold days with thin plates of *Lapis specularia*. Lettuce is mentioned by Charlemagne, and in the time of Albertus Magnus (1193–1280) it was grown throughout the year. From the Norman invasion of England until the middle of the sixteenth century, gardening appears to have been very greatly subordinated by the political unrest. Its development in the seventeenth century was closely bound with the herbalists Gerard and Parkinson. The initiation of French gardening, involving the protection of early plants with glass *cloches*, appears to have been due to Jean de la Quintinye in the second half of the seventeenth century, and crops were then brought to maturity upon hotbeds. John Evelyn, John Woolridge and Prof. Bradley added their quota of horticultural development in the succeeding hundred years, to be followed by J. C. Loudon. French gardening declined in the later half of the nineteenth century, however, only to give place to the more workable and convenient methods of glasshouse culture which provide our present supplies of extra-seasonal vegetables.

A New Cyclotron

The cyclotron constructed in the workshop of the Physics Department of Purdue University, Indiana, is described in the November issue of the *Journal of the Franklin Institute* by the five members of the staff who designed it. So far as possible standard materials available in industry have been used in its construction. The magnet is of low carbon steel 3 m. long and 2 m. high, and the pole pieces of special shape 1 m. diameter. The magnetizing coils are of thin copper tube through which cold water circulates. Each coil is square in section with side 30 cm. The oscillator is of the tuned grid tuned plate type, of frequency 10·9 Mc., with neutralizing condensers. It takes 3 amperes at 8,500 volts. The chamber is of the Berkeley type with floor and top of steel plate 3 cm. thick with special arrangements for controlling the bending due to external pressure, which has been found to increase the beam intensity. The ions are supplied by an arc near the centre of the cyclotron. The instrument yields 16·5 million volts for He^{++} ions.

The National Institute for Research in Dairying

The annual report of the National Institute for Research in Dairying, Reading, covering the year ending September 30, 1938, has just been published; this seems an unnecessarily long delay. Developments, administrative matters and changes in the staff are outlined, and a summary is given of the research work that has been carried out in the various departments. Among the last named is an investigation in the Department of Physiology and Biochemistry on the nutritive value of spray-dried milk, roller-dried milk and evaporated milk. The biological values of the proteins, and the content of vitamin A and of vitamin C are much the same for all three products, but vitamin B is much reduced in the evaporated milk—to half that present in the other two. The results show that properly dried milk retains to a remarkable extent the nutritive value of the raw product and that modern methods of spray drying yield a powder of high nutritional quality. An appeal is made for donations to meet the cost of new buildings which are urgently needed to relieve the acute congestion in the existing laboratories.

International Society of Medical Hydrology

A meeting of the general purposes committee of the International Society of Medical Hydrology was held in London on November 17 last to deal with emergency measures made necessary by the War, and also by the death of the Society's chairman of council, Dr. E. P. Poulton. Dr. J. Barnes Burt was elected interim chairman of council, and four additional vice-chairmen, all in countries 'neutral' in the present conflict, were appointed. It was further resolved that the cash balance remaining should be set aside for reconstruction of the Society after the War, and the general secretary was given indefinite leave of absence without pay and instructed to close the London office. The Society's address will be, until further notice, that of the honorary treasurer, Dr. G. D. Kersley, 6 The Circus, Bath.

Medical Organizations of India

The medical organizations of all-India are reviewed by Major-General Bradfield, director-general of the Indian Medical Service, in a volume of 658 pages entitled "An Indian Medical Review" (Government of India Press, New Delhi, 1938). Administrative organization and the medical profession and services, hospitals and nursing, maternity service and pharmacy, and medical education and research, are all surveyed in the first 280 pages, the remainder of the book containing full statistics of hospitals, dispensaries and other medical institutions. This volume should prove a useful supplement to the "Annual Report of the Public Health Commissioner with the Government of India".

The Night Sky in January

During this month, the night shortens in the latitude of London by 1 hour 10 minutes, reckoning from sunset to sunrise. The moon is new on January 9, and full on January 24. Occultations of stars by the moon include three stars of magnitude 3–4 of the Hyades cluster which precedes Aldebaran. The disappearances as seen from Greenwich take place on January 20 as follows: δ Tauri at 21h. 37·9m. at position angle 107° from the north point of the moon's disk: 64 Tauri at 22h. 31·1m. at 142° and 68 Tauri at 23h. 29·0m. at 16°. On January 23, λ Geminorum (3·6 m.) is occulted at 20h. 20·9m. at 121°. There is a fine array of planets in the evening sky—Venus, Mars, Jupiter and Saturn—whilst Uranus, a faint 6th magnitude object, is in Aries near the 6th magnitude star 53 Arietis. At the beginning of the month, Mars is overtaking Jupiter in the eastward shift of the two planets among the stars by about ½° a day, and on January 7 at 15h. there is a conjunction, the geocentric distance between the two objects being 1·2°. It is interesting to compare the colours and magnitudes of Mars and Jupiter when close together. Lunar conjunctions with the planets occur as follows: Jan. 8d. 10h. with Mercury; 12d. 13h. with Venus; 15d. 22h. with Jupiter; 16d. 7h. with Mars; 17d. 17h. with Saturn. In mid-January at about 22h., the southern meridian is bright with the stars of Taurus, Auriga, Orion, Gemini, Canis Minor and Canis Major. The Great Nebula of Orion shows to the naked eye as a hazy patch. The photographic plate is required to show the nebulosities, which, enveloping the Pleiades, are but the central condensation, according to Barnard, of an enormous nebula covering at least 100 square degrees. Not far from φ Tauri is a dark nebulous region giving the strongest proof, according to the same authority, of the existence of obscuring matter in space. Near ζ Tauri is the so-called Crab Nebula, which is No. 1 in the catalogue of 103 nebulæ drawn up in 1781 by Messier for his own use when searching for and identifying comets.

Announcements

THE Royal Meteorological Society's Symons Gold Medal for 1940 has been awarded to Prof. Dr. J. Bjerknes of the Geofysiske Institutt, Bergen.

THE Secretary for Mines has appointed Lord Cadman to be honorary adviser on oil, and Sir Harold Hartley to be honorary adviser on the development of home-produced fuels.

THE Minister of Health and the Secretary of State for Scotland have jointly appointed Dr. Edward Ellice Henderson, a medical officer of the Ministry of Health, to undertake the duties of inspector of anatomy in England, Scotland and Wales.

IT is of interest to put on record that Major-General A. G. L. McNaughton, commanding the Canadian Active Service Force which has recently landed in Great Britain, is a science graduate of McGill University and was president during 1935–39 of the National Research Council of Canada.

THE popular series of Gaumont British Instructional Films called "Secrets of Life" have now been made in colour using the Dufay process, and three of the present series of six were demonstrated at Film House on December 20. The valuable teaching aid that colour gives in educational films was apparent, and although many technical difficulties remain to be overcome, these films portraying the life-history of the burnet moth, the genetics of the lupin, the habits of badgers and other subjects have already reached a high level of efficiency. Mr. Oliver Pike's photographs in the badger film represent a real contribution to natural history.

DR. GEORGE W. CORNER, who has occupied the chair of anatomy in the University of Rochester (New York) since 1924, has been appointed director of the Department of Embryology, Carnegie Institution, Washington, D.C. He succeeds Dr. George Streeter, who has done so much to give the Department of Embryology of the Carnegie Institution its high place in the estimation of embryologists in all parts of the world. Dr. Streeter, who now retires, succeeded the first director—the late Prof. Franklin Mall. Dr. Corner's appointment has the warm approval of his fellow embryologists.

SIR WALTER LANGDON-BROWN has been appointed president of the British Social Hygiene Council in succession to the Right Hon. L. S. Amery, M.P.

A CHILD Guidance Clinic providing a limited service is available at Guy's Hospital for the hospital area.

ACCORDING to official statistics of the last fifty years, there has been a considerable reduction in the tuberculosis mortality in Germany. In women the mortality per 100,000 has fallen from 28·4 to 6·4 and in men from 34·2 to 7·8.

ACCORDING to the latest provisional figures issued by the United States Bureau of Census, the infant mortality reached a record low level of 50·9 per 1,000 live births in 1938, as compared with 54·4 in 1937. The rate has been decreasing steadily for twenty years: in 1915, when the birth registration area was established, it was 99·9.

THE Pan-American Congress of Rural Hygiene organized by the Government of Mexico and the International Congress of Otorhinolaryngology which were to have been held in 1940 have been postponed indefinitely owing to the War.

WE have received the first annual report of the Council of the Institute of Medical and Veterinary Science, Adelaide, South Australia. New laboratories of the Institute have recently been opened, of which an illustration is given. The Institute provides for the Adelaide Hospital, and for practitioners resident in the district, services in pathology, bacteriology and biochemistry, as well as work in veterinary pathology. A summary is given of the research work conducted by the staff of the Institute. This Institute was described by Sir Charles Martin in NATURE of August 26, p. 392.

Chronica Botanica, the international botanical journal published under the editorship of Dr. Frans Verdoorn, is to appear weekly from January 1940. This journal is unique among scientific journals, and contains digests, correspondence, quotations, comments on international affairs, news of institutions, experiment stations, gardens, societies, etc., personal notes and news, reviews, etc. The annual subscription will be 15 guilders, including postage. Further information can be obtained from *Chronica Botanica*, P.O. Box 8, Leyden, Holland.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

In the present circumstances, proofs of "Letters" will not be submitted to correspondents outside Great Britain.

Notes on points in some of this week's letters appear on p. 1094. Correspondents are invited to attach similar summaries to their communications.

Scientific and Technical Literature and Information

I have read with interest the editorial in Nature of November 25, 1939, concerning the need for a centre of documentation with the purpose of supplying original papers to scientific institutions and to libraries. Further aims of such a centre might be to prepare abstracts and translations, to set up complete documentation indexes and to take the role of a link between research institutes.

The difficulties pointed out in the editorial have been met with in France, too. I have the pleasure of announcing that a body similar to that suggested in Nature has just been brought into existence in this country, under the auspices of the "Centre National de la Recherche Scientifique" which is an autonomous Department of the Ministère de l'Education Nationale. This "Service de Documentation" undertakes the following tasks:

(1) to receive and to keep all scientific periodicals which are considered to be of importance for complete documentation covering the fields of chemistry, physics, applied chemistry, technical physics, biochemistry, and some branches of biology;

(2) to abstract these periodicals in the form of very short summaries including title, reference, and a few lines intended to locate accurately the contents of each paper;

(3) to edit and to publish a printed bulletin, to appear twice a month, and to supply it to the institutions concerned;

(4) to reproduce on microfilm single original papers wanted by laboratories and research institutes; to supply positive copies of such microfilms; to keep the negatives;

(5) to establish several card indexes of the abstracts, by authors, by subject matter and so forth, so as to facilitate quick compilation of complete dossiers on a given subject, whenever asked for;

(6) on request, to supply translations of papers published in unusual languages.

This "Service de Documentation" was created on November 16, 1939, and it is hoped that the first bulletin may appear within a few weeks. The Service is to act in close collaboration with French scientific societies, especially those which have been publishing scientific abstracts.

I shall be very glad to get in touch with people dealing with the same problem in Great Britain, in view of possible collaboration in this matter between our two allied countries.

P. Auger.

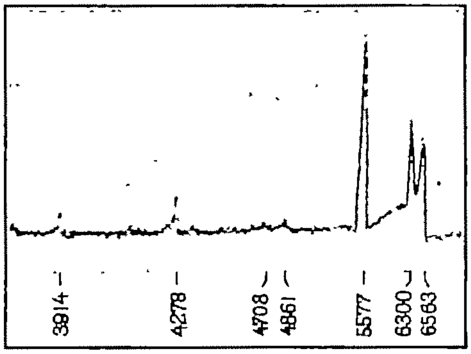
Service de Documentation
du Centre National de la Recherche Scientifique,
18 rue Pierre Curie, Paris, Ve.

Hydrogen Showers in the Auroral Region

Previous investigations have shown that the hydrogen lines are usually absent from spectrograms of the auroral luminescence. Even when the stronger lines and bands are much over-exposed and also very faint lines appear, there may still be no trace of the H-lines visible on the spectrogram[1,2,3,4]. This does not mean, however, that hydrogen may not occasionally appear in these regions. On the contrary, some years ago I gave, for the luminous night clouds, an explanation[5] based on the assumption that showers of hydrogen, coming from the sun, entered into the atmosphere and combined with oxygen, for example, in the atomic or ozone state, to form water vapour. At the altitude of the luminous night clouds (80 km.), the atmospheric pressure might be sufficiently great for the water vapour to condense and produce clouds of ice needles.



During an auroral display on October 18 this year, we obtained at Oslo auroral spectrograms indicating the existence of such hydrogen showers. In the region of long waves, two spectrograms from auroral arcs showed the green line (5577) and the red one (6300) with considerable density. The 1st positive group, however, was scarcely visible; but far in the red end and well separated from the line (6300), a strong line appeared with a wave-length (6560) which within the limit of error coincides with H_α (6563). Now this coincidence might be accidental, but on the first of our spectrograms (exposure from 19.15–20.13 M.E.T.) where the spectrum appeared with greatest density, another line appeared for which we found the wave-length 4860, which within the limit of error coincides with H_β (4861).

This line, which is usually absent in the auroral spectrum, now appeared with a density twice that of the negative band 4708 and about two thirds that of the strong band 4278. A spectrophotogram of the spectrum is shown in the accompanying reproduction.

The simultaneous great enhancement of two lines, one of which coincides with H_α, the other with H_β, can scarcely be accidental, and our spectrogram thus would show that *occasionally considerable quantities of hydrogen are present in the auroral region.*

The fact that the hydrogen concentration usually is too small to give detectable lines would show that *the occurrence of strong hydrogen lines must be due to showers of hydrogen or to a kind of 'hydrogen radiation' occasionally coming from the sun.* The hydrogen is then removed from the auroral region through the formation of water vapour and condensations, which may appear as luminous night clouds.

Origin of the λ 4932 Emission in the Spectra of Novæ

MESSRS. J. DUFAY AND M. BLOCH[1] have recently discussed the presence of a faint emission band at about 4932 A. in the spectra of Nova Herculis (1934) and of Nova Aquilæ (1918), and have suggested that the radiation is to be identified with the forbidden ${}^3P_0-{}^1D$ transition of O (III), the companion of the N_1 and N_2 lines at 5007 and 4959 A. respectively. This assignment, as was mentioned by Dufay and Bloch, was made by Bowen and Wyse in the spectra of N.G.C. 6572 and 7027, and the line was later observed also in N.G.C. 7662[2].

While the identification is probably correct in the nebulæ cited, it appears to be open to question in the novæ, particularly in Nova Aquilæ (1918). The maximum observed by me at 4932 A. in the spectrum of this nova is very probably only a subsidiary maximum in the broad N_2 emission band, centred at 4959 A.; such is the interpretation in my paper[3], to which Dufay and Bloch make reference. The relatively strong continuous spectrum, as well as the great width of the bands themselves (approximately 50 A.), tends to obliterate the faint radiations. Therefore if a *bona fide* emission band were present at 4932 A., it would probably have to be at least 1/10 or 1/20 as bright as N_2 in order to be detected, and thus it could not be the ${}^3P_0-{}^1D$ emission, which is much fainter both by prediction and by observation in the nebulæ.

The case for Nova Herculis (1934) is not so clear-cut. The Lick Observatory spectrograms of 1935 and 1936 confirm the observation of Dufay and Bloch of a faint emission at 4932 A. The emission appears to be several times stronger with reference to N_1 and N_2 than in the nebulæ, thus suggesting some other identification. The difference, however, may possibly be attributed to the differing contrasts of the two emulsions involved. Another approach to the question consists in examining the constancy or variability, in Nova Herculis, of the intensity ratio, I_{4932}/I_{4959}, which should be an atomic constant for O III. Two Lick Observatory spectrograms, dated September 26, 1935, and May 1, 1937, both record the N_2 emission as of about equal density, the image on the latter plate being slightly denser than on the former. The 4932 A. line appears definitely on the former plate (density about 0·8), while on the latter plate it is absent. Inasmuch as the two spectrograms have been made on the same type of emulsion and have been developed in the same way, and further, since both plates are capable of showing the lines resolved, the inference is that the 4932 A. line faded in the interval, with respect to N_2, by a factor of at least 10, and that it is therefore not chiefly attributable to O III.

Perhaps this observation should not be taken at its face value, in view of the possibility of solarization of the strong lines on one or both of the plates, or other spurious photographic effects. In any event, there appears to be room for doubt regarding the assignment of the nova emission at 4932 A. to O III.

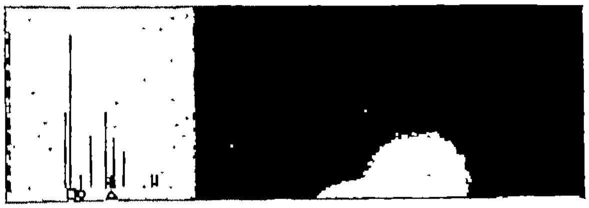
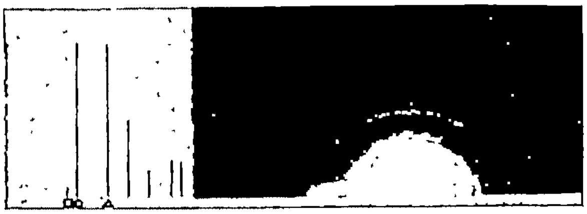
Electron Diffraction Examination of Oxide Films on Light Metals

WHILE iron rusts quite easily in air, such baser metals as aluminium, magnesium, zinc, etc., do not manifest this tendency and retain their metallic lustre for a considerable length of time. This commonplace fact is interesting but requires experimental study for a full understanding. For a study of metal surfaces as in these cases, the method of electron diffraction is most powerful.



MAGNESIUM AT ROOM TEMPERATURE.



MAGNESIUM AT 400° C.
□ INDICATES THE EXISTENCE OF MG. ○ AND △ INDICATE THE EXISTENCE OF MGO.

Electron diffraction photographs of magnesium specimens, prepared by polishing the surface with a coarse sandpaper, were taken after exposing them to air at room temperature, at 200° C., at 300° C., and at 400° C. Of the two photographs reproduced, one is that of the specimen at room temperature and the other is that of the specimen heated at 400° C. In the graphs, the horizontal distance from the origin is the radius of the ring while the length of the lines is a measure of the intensity by visual estimation.

The most intense ring of MgO is found, though faint, in the pattern of the specimen left in the air at room temperature; likewise, the most intense ring of Mg is seen faintly in the pattern of the specimen heated at 400° C. It has therefore been concluded that magnesium metal is masked with a thin film of magnesium oxide (MgO) even at room temperature, and the film is still quite thin even after heating at 400° C. Such a thin film, 10 A. or so in thickness, protects the metal and keeps it lustrous for a long time.

Although it is very difficult to obtain the patterns of the aluminium oxides by the reflection method[1], we succeeded in producing them by making deep ditches on the metal. Precisely as in the case of magnesium, it was possible to verify that the surface of aluminium at room temperature is covered with a film of γ-Al_2O_3, while the specimen heated at 500° C. is covered with a film of α-Al_2O_3.

With beryllium left exposed at room temperature, the pattern obtained from the surface precludes the possibility of even a trace of rings belonging to the oxide BeO.

Full details of these experiments will be published in the *Scientific Papers* of our Institute.

Decomposition of Hydrogen Peroxide by Catalase

THAT the catalytic decomposition of hydrogen peroxide by catalase requires the presence of molecular oxygen was demonstrated by a number of manometric experiments previously described[1]. Being, however, well aware of certain difficulties in this kind of work, we have given a detailed account of our methods so that our experiments could easily be repeated.

The failure by Weiss and Weil-Malherbe[2] to confirm our results can only be ascribed to some defects in their experimental procedure and to the fact that they have not closely followed the recommendations put forward in our paper.

Our criticism[3] of experiments with luminescent bacteria was not solely due to the purely qualitative character of this work[4], but mainly to the fact that under the conditions of these experiments even a 90 per cent inhibition of catalase could not be detected.

That the curves of inhibition shown in our paper are not of autocatalytic type can be explained by the instability of pure catalase at high dilutions (0·0005 mgm. per flask) used in our experiments.

Moreover, our manometric experiments, which we have repeated several times since the publication of our paper, are in complete agreement with the results we have obtained from the study of catalase inhibited by sodium azide or by hydroxylamine[5]. Both these inhibitors combine reversibly with catalase giving well-defined compounds.

It is, however, important to remember that free catalase and azide- or hydroxylamine-catalase are very similar compounds displaying the same general properties. Thus, their iron is in the trivalent state, they show a typical methæmoglobin-like absorption spectrum, they share the remarkable property of not being reduced by a powerful reducer like sodium hyposulphite and they react with hydrogen peroxide.

While the reaction of free catalase with hydrogen peroxide is extremely rapid and therefore inaccessible to spectroscopic study, that of azide- or hydroxylamine-catalase is on the contrary slow and can easily be followed spectroscopically. The study of this reaction clearly shows that azide-catalase treated with hydrogen peroxide undergoes reduction which is marked by a distinct change in its colour and its absorption spectrum and by the appearance of the property, shared with other divalent haematin compounds, of combining with carbon monoxide. On the other hand, the reduced azide-catalase cannot be oxidized by hydrogen peroxide although it can be oxidized by molecular oxygen, which in this reaction is reduced not to hydrogen peroxide but to water. In this respect catalase, unlike many autoxidizable compounds, resembles cytochrome oxidase and probably polyphenol oxidase which on reoxidation reduce oxygen to water. Azide and hydroxylamine inhibit the activity of catalase only because they slow down the reoxidation of ferrous catalase by oxygen.

Our conclusion that catalatic decomposition of hydrogen peroxide is brought about by a constant reduction of catalase iron by hydrogen peroxide and its reoxidation by molecular oxygen is therefore well supported by two independent experimental approaches to the problem, namely the manometric and spectroscopic studies of the enzyme. The importance of specific inhibitors and of spectroscopic methods in the study of enzymes is now universally recognized and can scarcely be over-estimated. In very few cases, however, can the importance of these methods be so clearly demonstrated as in the study of catalase.

Considering that a pure or even crystalline catalase showing strong colour and absorption spectrum can be so easily prepared, the workers[2] interested in the intimate mechanism of catalatic activity should attempt to prepare such an enzyme and to acquire thus a first-hand knowledge of its properties.

The fact that the results of our experiments do not agree with certain theoretical considerations[2,6] concerning the possible mechanism of catalytic activity of this enzyme suggests only that these considerations require some revision.

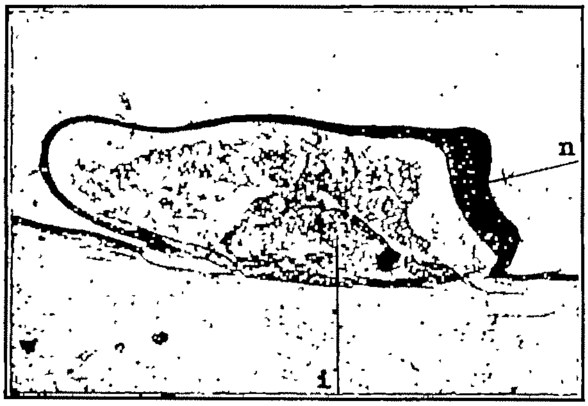
Evocation in the Chick

WORK on the evocation of neural tissue in vertebrate embryos by chemically prepared substances has hitherto been confined to the Amphibia[1]. But since in the induction of neural tissue in general the chick has shown considerable similarities to the newt, especially in the inducing activity of its organizer when coagulated[2], and in the inducing activity of fully differentiated tissues[3], there was reason to believe that it would respond in a similar way to chemicals. This was not tested, however, owing to a technical difficulty: any implant of dead material becomes surrounded by mesenchyme, and consequently isolated from the reactive ectoderm[2].

This difficulty has recently been surmounted. The substance to be tested, dispersed in a piece of coagulated egg albumen by Waddington's method[4], is inserted between the endoderm and ectoderm (presumptive epidermis) in the antero-lateral region of the area pellucida of a blastoderm in the early primitive streak stage. This region of the area pellucida, together with the adjacent area opaca, is then isolated, no part of the primitive streak being included with it, and the isolate is grown *in vitro* by Waddington's method[3]. At the time of isolation no mesoderm is present in this part of the blastoderm, and since the primitive streak is eliminated none afterwards appears in it.

Controls with no implant formed no neural tissue, and only very occasionally a slight epidermal thickening, provided the antero-medial region of the area pellucida was not included. Controls of albumen alone commonly showed a slight epidermal thickening.



EVOCATION BY SODIUM-1:2:5:6-DIBENZANTHRACENE-ENDO-α-β-SUCCINATE.
i, IMPLANT; *n*, NEURAL PLATE.

All the chemical substances tested on the chick had previously been shown to be active in the Amphibia[4]. One satisfactory evocation of a neural plate was obtained with sodium-1:2:5:6-dibenzanthracene-endo-α-β-succinate (see figure). The most usual result with this substance, however, was an extension in area of the ectoderm, together with a non-neural thickening; the latter varied from a histologically epidermal thickening little greater than those found in the controls, to a large thickening histologically like early neural tissue. One induction, in which, however, the origin of the ectoderm is not certainly established, was obtained with 1:2:5:6-dibenzanthracene, which is carcinogenetic in the adult fowl[6]. Styryl 430, very active in Amphibia[4], was only slightly more active than plain albumen in the chick. 1:2-dihydroxy-1:2-di-α-naphthylacenaphthene was no more active than plain albumen. A probably impure specimen of naphthalene, of moderate activity in Amphibia[4], was the most active substance tried: three good evocations were obtained with it. Impure glycogen, active in Amphibia, produced no neural tissue, but a very marked proliferation of epidermal cells.

Presumptive epidermis, coagulated by heat or acetone, was also tested. One good evocation, and one almost positive, were obtained (both acetone coagulation), and various degrees of thickening were produced in other specimens. As in Amphibia, therefore[7], the presumptive epidermis, which is the indicator of evocating activity, can itself be made to become an active evocator.

The conclusion from these results is that the process of evocation is fundamentally similar in the chick and in the newt, in that it can be produced by chemicals and by coagulated presumptive epidermis. But the chick is rather refractory material, and there are clear indications that the degree of its reactivity to individual chemicals is different from the newt's.

Growth-stimulating Effects of Extracts of Normal Adult Tissues and Tumours

IN investigations on the physiology of neoplastic growth, the conceptions are often encountered that the malignant cell has an unusually high growth capacity as compared with the normal cell, and that neoplastic tissue is especially rich in growth-promoting factors.

Recent work has shown clearly that the first notion is untenable. Studies on tumour tissue growing *in vitro* have proved that the growth capacity of neoplastic cells is not greater than that of normal embryonic cells[1]. Furthermore, as we have recently shown, cells from adult organisms grow as well *in vitro* as those of embryos[2]. These facts make it clear that the distinction between normal and neoplastic cells is not to be found in any unusual growth potentiality of the latter. So long as growth-promoting substances are present, cells outside the body behave alike whether they originate from embryonic, normal adult, or tumour tissue.

The conception that neoplastic growth is connected with the presence of a large amount of growth-stimulating factors in tumour tissues would appear to have been confirmed by the experiments of Carrel and Burrows[3], Carrel[4,5], Mottram[6], Bisceglie[7] and Drew[8], all of whom demonstrated the marked cell growth-stimulating action of extracts of tumour tissue. However, since recent experiments[9,10] have shown that extracts of normal adult tissue are also powerful growth stimulators, we thought it important to determine whether the stimulating effect of tumours is in reality exceptionally high, and whether it is greater than that of normal tissue.

We compared quantitatively the growth-stimulating effect of extracts of tumour tissue with those of normal adult tissue extracts. Cardiac and smooth muscle of chickens were used in the preparation of extracts of normal adult tissue, Rous sarcoma for tumour extracts. Young tumours, about olive size, without visible necrosis, were selected. The finely minced normal and malignant tissues were each extracted in four times their volume of Tyrode. The resulting extracts were used in their original concentration. The stimulating action of extracts was tested quantitatively on fibroblast cultures grown in Carrel flasks, prepared according to the standard technique. The growth-rate of the colonies was measured daily, according to the method of Ebeling, over a period of seven days. The medium was not changed during this period. The fibroblast colonies in both cases were uniform and regular in structure but the cells growing in tumour extracts were somewhat more granulated.

Our experiments showed that the growth-activating effect of the sarcoma extract is certainly not greater, but on the average rather weaker, than that of adult muscle extracts. The mean for the growth-activating effects of the tumour extracts is about 75 per cent of the latter.

The peculiar behaviour of malignant cells in the organism is, therefore, obviously not to be found in any unusually high growth capacity of these cells, or in any unusually high amount of growth-promoting substances in neoplastic tissue. In order to explain the autonomous growth of the malignant cell it is necessary to postulate some intrinsic change in the mechanism which in the body normally controls and holds in check this *ever-present* growth potentiality.

Details of our experiments will appear elsewhere.

Stamen Lodicules in Maize

AMONG some maize plants (Sutton's White Horse Tooth) originally planted in connexion with other work, there appeared one which bore anomalous male flowers the morphology of which may be worth recording. In the tassel of this plant, in a considerable number of cases, the lower flowers in each spikelet possessed only two stamens; sections showed that often both flowers in the spikelet were abnormal.

A illustrates a spikelet in which flower 1 has three 'lodicules' and three stamens, while flower 2 is normal. *B* shows flower 1 with two 'lodicules' (one of which is bifid at the tip) and two stamens, while flower 2 has three 'lodicules' and three stamens. In both flower *A*1 and *B*2 the 'extra lodicule' is united with the anterior stamen towards the base. In flower *B*1 the anterior part of the bifid lodicule would seem to represent the missing anterior stamen.

Thus the 'extra' lodicule does not seem to represent the 'missing third lodicule' of the grass flower but appears to be a replacement of or an outgrowth from the anterior stamen, and would come under the category of what Arber[1] has called stamen-lodicules and recorded for the bamboo Cephalostachyum, where it is also the front outer stamen which most frequently becomes lodicular.

Effect of Suint on Sheep Dips

EXPERIMENTS carried out in this Department have shown that the addition of wetting agents to an arsenic dip results in a decreased retention of arsenic in the fleece; the wetting agent causes the dip to penetrate the fleece more readily, but it also facilitates drainage from the fleece after immersion. Suint, the water-soluble matter in sheep's wool, is well known to have good wetting properties, and this material must accumulate in the bath when large numbers of sheep are dipped. In order to determine what effect suint has, observations were made at a routine dipping of 264 Welsh yearlings at the College Farm. Samples of the dip were collected at the beginning and end of the dipping; also, observations were made on the first and last three sheep through the dip, the wool samples being taken from the back. The accompanying table gives the results.

	Initial dip	Final dip
% soluble As_2O_3	0·118	0·125
% soluble matter	0·19	2·66
Surface tension: dynes/cm	73·0	48·3
	First 3 sheep	Last 3 sheep
Duration of protection against experimental myiasis (weeks)	3	2
% soluble As_2O_3 in wool at base of fleece 6 days after dipping	0·44, 0·51, 0·58	0·12, 0·23, 0·25
% decrease in soluble As_2O_3 content of whole staple from 6th to 20th day after dipping	23	57

It will be seen that there is a remarkable difference between the sheep dipped at the beginning and at the end; this result is not due to the dip becoming weaker but to the extraneous material introduced during dipping. The change in the physical properties of the dipping fluid was mainly due to suint; this material contains a high proportion of fatty acids and markedly lowers the surface tension of water. Shortly after dipping, the arsenic content of the fleece was considerably lower in the sheep dipped last as compared with those dipped first; also, the arsenic disappeared from the fleece more rapidly and poorer protection was afforded against experimental infestation with sheep maggots (by the method of MacLeod[1]).

It has long been realized by farmers that the dipping fluid becomes less effective in protecting sheep against maggot flies after a large number of sheep have been through the bath. This has usually been ascribed to contamination of the dip with dung and urine, materials which attract the fly. The present results suggest that the presence of suint in the bath may be of more importance, since this changes the physical properties of the fluid and results in a smaller and less stable deposit of poison in the fleece. Further work is in progress to find methods of preventing the deleterious effects of suint in the dipping bath.

This dipping at the College Farm was carried out in the spring with sheep in almost full fleece, but the animals were small and in poor condition after a hard winter. Higher concentrations of suint probably occur at larger dippings, especially of lowland sheep in good condition.

Points from Foregoing Letters

IN spectrophotograms of the auroral spectrum taken on October 18, L. Vegard has observed great enhancement of two lines coinciding with the two well-known lines of the hydrogen spectrum. This indicates the occasional presence of considerable quantities of hydrogen in the auroral region, which are due possibly to 'hydrogen showers' from the sun.

A. B. Wyse discusses the interpretation of a faint band at about 4932 A. in the spectra of Nova Herculis (1934) and of Nova Aquilæ (1918). Radiation from nebulæ in this region is probably due to oxygen. On the other hand, that from novæ is believed to be due to nitrogen.

I. Iitaka and S. Yamaguchi submit electron diffraction photographs of specimens of magnesium at room temperature and at 400° C. These indicate that magnesium after polishing with glass paper is covered by a thin film of oxide even at room temperature. A film of oxide also appears to exist on aluminium, but no trace of a film was found on beryllium.

M. Abercrombie has shown that evocation of neural tissue by chemical substances, including carcinogens, is possible in the chick embryo. Coagulated presumptive epidermis is also an evocator. The process of evocation in the chick is fundamentally similar to that in the newt, though the degree of reactivity of the former to individual chemicals is different from the newt's.

R. S. Hoffman, E. Tenenbaum and L. Doljanski find that the activating effect of Rous sarcoma extracts on the growth of fibroblast cultures *in vitro* is not greater than that of extracts of normal adult tissue. The significance of the facts that neoplastic tissue has neither an unusually high growth-capacity nor an unusual wealth of growth-promoting agent as compared to normal tissue, and their bearing on the behaviour of malignant cells in the organism, is discussed.

Anomalous male flowers of maize (Sutton's White Horse Tooth) are described and illustrated by B. C. Sharman, where the anterior stamen is replaced by or arising in association with a third 'lodicule', akin to the stamen-lodicules described by Arber for Cephalostachyum.

Suint, the water-soluble material in sheep's wool, has good wetting properties. Observations by R. P. Hobson suggest that the accumulation of suint in the bath during dipping has a pronounced effect on the physical properties of arsenic dips; this results in a lower content of arsenic in the fleece and poorer protection against infestation by sheep maggots. Work is in progress with the view of finding methods of preventing the deleterious effects of suint in the dipping bath.

RESEARCH ITEMS

India and Crete

A SIMILARITY between pottery found at Maniyar Math in Rajgir, southern India, and finds in Crete is suggested by J. G. Aravamuthan in *Man* of December 1939. The Indian pottery vessels are attributable to an age roughly anterior to the Christian era, and are said to bear spouts varying in number from four to twenty, or even thirty-four in one instance. On the spouts were designs described as "serpents, sieves, animals, etc.". Associated with the finds were terra-cotta images of hooded snakes and a large stone slab containing a number of hooded figures. Mani Naga was the protector and rain-giver of Rajagirha. The name of the god implies association with the serpent. Finds in Crete resembling the Indian vessels appear to be adaptations of drain-pipes, on which the representation of snakes moulded in relief in certain instances points to their use as places of refuge for snakes, while cups on the outside might be used to supply them with milk or other refreshment. In another type a snake is coiled around a naturally formed honeycomb. In still another a snake peeps into the mouth of the jug. Several show snakes approaching or peeping into a cup. The earliest known of this class is a vessel in the form of a female with snakes coiling round the neck. The Cretan vessels are thus multifarious in form and have evolved into a number of varieties. The Rajgir spouted and perforated vessels embody features found in one or other of these varieties. The link between India and Crete seems evident, but beyond relation to a snake cult and a necessary connexion with bringing down rain, the purpose is obscure.

Volcanic Action in Minoan Crete

SIR ARTHUR EVANS has suggested that the catastrophes which archæological research has revealed overwhelmed the Cretan palaces of the Minoan civilization were caused by earthquakes. An alternative theory that they were due to volcanic action from the island of Thera similar to the explosion of Krakatau in 1883, is put forward by Sp. Marinatos in *Antiquity* of December. The ground for this suggestion is the result of a recent excavation on the site of Amnisos, a settlement on the coast of Crete, destroyed at the same time as Nirou Khani, Malia, Gournia, Zakro, and perhaps others. At Amnisos one of the buildings, quite near the sea, at the deeper levels was buried under a mass of pumice stone and sand, and a square pit inside the building was full of pumice stone. A reconstruction of the catastrophe suggests that sea waves broke over the building and carried it away almost to its foundations. It was abandoned and later the north breezes brought the pumice stone from the volcano. This receives support from the fact that the pieces of pumice were all small, rounded and polished like pebbles. At the "Villa of the Frescoes" higher up the beach there was no pumice, but the walls had collapsed in a remarkable fashion due to some tremendous natural force—surely the waves after an eruption. It has been pointed out that much additional support from excavation on selected sites would be necessary to convince archæologists generally of the truth of this explanation.

Toxicity of Indene

THE destructive action of heavy coal tar naphtha on the bed bug appears to depend largely on the presence of unsaturated constituents, especially indene (C_9H_8). The high price of this hydrocarbon prohibits its use on a large scale, but the indene content of naphtha can be increased without unduly raising the cost, and information concerning the toxicity of indene to man is therefore desirable. G. R. Cameron and Cecile R. Doniger have investigated its toxic effects on rats, mice and guinea pigs, and find that in high concentration or on administration of large amounts it causes necrosis of organs such as the liver and spleen. Indene cannot therefore be regarded as a highly noxious agent; but the authors consider that a limit should be imposed on the indene content of such insecticides as heavy coal tar naphtha (*J. Path. and Bact.*, 49, No. 3, 529).

Control of the Potato Root Eelworm

IN experiments carried out on small field plots at the Albert Agricultural College, Glasnevin, a very promising degree of control of the potato root eelworm, *Heterodera schachtii*, has been obtained by J. Carroll using trap-cropping with potatoes. Sprouted potatoes were planted in plots of 'potato sick' land on April 1, 1938. Five weeks after planting date the plants, and tubers from which they grew, were removed from the soil. No effort was made to remove the roots of the plants as this was found to be unnecessary. After removal of the trap crop plants, turnips were sown in the plots. In 1939 very good crops of potatoes, showing no obvious overground symptoms of eelworm infestation, were produced on the plots which had been trap-cropped in 1938. Control plots exhibited typical severe symptoms of eelworm infestation. Further experiments demonstrated that the removal of two successive trap crops in one season did not produce markedly better results than the removal of one trap crop. Experiments are proceeding on a larger field scale.

Trisomic Nicotiana

T. H. Goodspeed and P. Avery (*J. Gen.*, 38, 381–458; 1939) have given an account of the trisomic and other types found in *Nicotiana sylvestris*. 164 trisomic plants including eleven different primaries, 21 tetrasomics, 45 double trisomics, 13 triple trisomics and 30 variant trisomics have been found in about 9,000 plants. These have arisen from irradiation by X-rays, from plants homozygous for a gene causing asynapsis, or from the cross triploid × diploid. The morphological appearance of the trisomics are described, while the presence of an extra fragment also has a characteristic effect. Transmission of the primary trisomics through pollen and ovules is relatively high, but varies with the particular trisomic. The chromosomes of *Nicotiana sylvestris* and their relationship to nucleolus formation are described. The somatic expression of diploid *N. sylvestris* represents an interaction of the various growth rates of organs and tissues which differentiate the primary trisomics.

Breakdown in Stored Plums

INTERNAL breakdown is common in plums stored for protracted periods at low temperatures. The variety Monarch, which is particularly susceptible to this type of trouble, has been studied at various storage temperatures by W. H. Smith (*J. Pom. and Hort. Sci.*, 17, 284; 1939). The fruit, which was 'pre-climacteric' at the time of picking, was divided into 'more mature' and 'less mature' batches and stored at seven temperatures between 65° F. and 31° F. Samples were removed from store at intervals of seven days and cut open for examination. Greater maturity at picking had the effect of advancing the time of the first appearance and maximum development of physiological breakdown. The relative amounts of breakdown at different temperatures were unaffected by differences of maturity. Maximum breakdown after 14–21 days of storage occurred at medium temperatures. After longer periods higher maxima occurred at progressively lower temperatures. The minimum percentage of breakdown always occurred at 34° F., the amount rising rapidly at both lower and higher temperatures. Two distinct types of injury, appearing as 'internal browning' and 'jellying', were recognized. At 45° F. and above, the plums are susceptible only to jellying, this type of injury falling to nil with rise of temperature. At 34° F. and below, they are susceptible only to browning, susceptibility increasing rapidly with reduction of temperature. Between these temperatures both types of injury may occur in the same plum or different plums in the same batch.

Rose Propagation

ROSE cuttings generally root with considerable difficulty, yet little work on propagation by stem cuttings has hitherto been undertaken. Dorothy Brandon (*J. Pom. and Hort. Sci.*, 17, 233; 1939) has studied the differences in rooting properties of a large number of members of the genus Rosa and the effects of various treatments to encourage rooting. The suggestion that high starch content is correlated with easy rooting has been likewise examined. Hardwood cuttings of twenty-six species and varieties were taken at intervals throughout the winter, the highest percentage of rooting being obtained in the period October-December. June was found to be the best time for inserting softwood cuttings. The effects of treatment with ethylene chlorhydrin, thio-urea, sodium nitrate, glucose, and indolyl acetic acid were tried. The two latter increased rooting slightly whilst the two former substances depressed it. No treatment was found to give results sufficiently beneficial to be of practical value. Fluctuations in starch content during the season varied according to species and variety, botanically related species and varieties falling into the same groups. Starch persisted throughout the winter in some species and disappeared in others. No correlation was found to exist between the starch content of cuttings and facility of rooting.

Kernel Smut of Sorghum

A SMUT disease of the Sorghum plant causes damage in Egypt, but Dr. A. F. El-Helaly has recently shown that it can be controlled at negligible cost by treatment of the seed with an appropriate fungicide ("Studies on the Control of Kernel Smut of Sorghum". Min. Agric. Egypt, Tech. and Sci. Service Bull. 238. Govt. Press, Bulâq, Cairo, 1939. P.T.3). The disease is caused by the fungus *Sphacelotheca Sorghi*, and is usually most severe upon early sowings of the host crop. The range of temperature within which both grain and fungus spores will germinate is wide in the months of April and May, but becomes narrow in June and July, being so limited in the latter month that the disease is rare. 'Herati' sowing, where the soil has a considerable water content when the seed is sown, favours the parasite more than the 'Afir' method of sowing in dry soil which is irrigated later. Control was obtained by treating the seed with organic mercury germicides, either 2·5 or 5 gm. of agrosan *G* per kilogram of seed, or a 1–2 per cent solution of uspulun or germisan. An interesting effect was demonstrated with sulphur and copper carbonate, the toxic effect of which was increased by using soil filtrate in place of distilled water in the preparation of fungicidal liquid.

Composition of Ancient Greek Bronze Coins

A LONG monograph by E. R. Caley on "The Composition of Ancient Greek Bronze Coins" contains a large number of analyses and four plates of microphotographs (*Mem. Amer. Phil. Soc.*, 11). One interesting general result of the study is the variation in the proportion of tin and lead in the bronzes, the amount of lead increasing in the more debased coinage of later periods. The author discusses the probable causes for this varying ratio. Re-melting old coins with lead was one cause; others were the technical requirements of minting, adverse economic conditions, disruption of trade by wars, and scarcity of tin. The study is of considerable archæological and historical, as well as chemical interest. It is published at 2.50 dollars by the American Philosophical Society, Philadelphia.

Stereochemistry of Complex Inorganic Compounds

THE reaction of dichloro-diethylenediamine cobaltic chloride, $[\mathrm{Coen_2Cl_2}]\mathrm{Cl}$, with potassium and silver carbonates was the first example of the Walden inversion in the field of inorganic complex compounds, the *l*-form being converted into the *d*-form of the carbonate compound, $[\mathrm{Coen_2CO_3}]\mathrm{Cl}$, in the case of potassium carbonate, and the *d*- or *l*-forms of $[\mathrm{Coen_2CO_3}]_2\mathrm{CO_3}$ in the case of silver carbonate. J. C. Bailar and J. P. McReynolds (*J. Amer. Chem. Soc.*, 61, 3199; 1939) have now prepared two diastereoisomeric forms of the propylenediamine compound $[\mathrm{Copn_2CO_3}]_2\mathrm{CO_3}$ by a Walden inversion method. Rotatory dispersion curves for these and for *cis*-dichloro-di-*l*-propylene-diamine cobaltic carbonate, by comparison with the curves for the analogous diethylenediamine series, lead to a determination of which of the two carbonate forms is obtained by an inversion about the central cobalt atom in the latter case. It is further suggested that the mechanism of the production of the two forms of the carbonato complex is as follows: The non-inverted form is produced through the preliminary displacement of the Cl ions in the *cis*-dichloro-di-*l*-propylenediamine cobaltic chloride by water molecules, followed by displacement of H_2O by CO_3, whilst the inverted form is produced by direct substitution of CO_3 for Cl within the complex. Either form could be produced with silver carbonate alone or potassium carbonate alone by varying the experimental conditions, and the inverted form of carbonato diethylenediamine cobaltic carbonate was produced, for the first time, by using potassium carbonate.

RECENT RESEARCHES ON EARLY MAN IN CHINA. II

'MODERN MAN' IN EASTERN ASIA[1]

"THE Upper Cave" of Choukoutien, discovered in 1930, and excavated in 1933 by Mr. W. C. Pei, is situated at the top of the hill about 175 m. above sea-level, opening to the north and north-east side of the hill. It represents a dissolution cavity in the original limestone massif and is completely separated from the Sinanthropus beds except at the entrance and at the bottom of the so-called 'lower recess'. It seems, therefore, that at the time of Sinanthropus, the cave was not accessible, but was reopened later in Upper Palæolithic times. The deposit is quite different from that of the Sinanthropus cave, being a grey loam intermixed with small angular limestone fragments. In it was discovered an unimaginable wealth of bones of fossil animals: hares, deer, tigers, bear, hyæna, ostrich and representatives of other genera.

The remains of at least seven human individuals were found with a very interesting series of archæological objects. Both fauna and geological conditions assign the finds of the Upper Cave to the Upper Palæolithic. With the exception of the finds in Palestine, no similar discovery has been made anywhere in Asia, and interest turns at once to the character of the human remains, which Prof. Franz Weidenreich considers "of the greatest importance for . . . the racial history of entire mankind".

Although seven individuals are represented, three skulls only afford evidence of physical appearance. The remainder are too fragmentary for that purpose, and the individuals, who it is presumed belonged to one family, had suffered a violent death; although the presence of hæmatite points to the ritual of burial, either the bodies were violently disturbed, or were dismembered before burial.

Analysis of the characteristics of the three skulls sufficiently complete for evidential value in this connexion leads Prof. Weidenreich to the conclusion that while the skull of the male adult, an old man more than sixty years of age, bears some resemblance to European skulls of the Upper Palæolithic Cro-Magnon, Obercassel or Mechta, it is more primitive in the development of the supra-orbital region, and the lowness of the brain-case. Of the two females, however, one in its hypsacrocranial character and certain other features presents the appearance of Melanesian affinities, while the second is Eskimoid. Viewing the characters of the male skull in the light of these findings, it is possible to regard it as a primitive Mongoloid.

The occurrence of these three types among members of a single primitive group or family suggests that the mixture of types is not a consequence of the conditions of modern civilization, but that at an early stage of evolution individual variations appear which become fixed as a result of the dominance of certain features and of isolation. Hence the conclusion is reached that the tendency to breed and cultivate unitary groups corresponding to the suggestion of the theory of 'pure races' does not represent primary conditions, but a later acquisition.

THE UPPER CAVE INDUSTRY OF CHOUKOUTIEN[1]

The cultural evidence of the existence of man of Upper Palæolithic age on this site has been studied by Mr. W. C. Pei, who discusses the objects collected, the technique of workmanship, the character of the culture, and the relationship of the Upper Cave culture with that of Europe.

Objects collected. Among stone implements the choppers are remarkable. A great number of water-worn pebbles and boulders have been found, but only a few have been worked. A good example is a green stone which has been knocked into shape with a few heavy strokes, making a blunt edge on one part of the pebble, for use as a chopper or hammer-stone. Other implements are mostly made of flint or quartz flakes. 'Bipolar' implements made of vein quartz are very similar to those associated with Sinanthropus, though geologically much later. Of bone artefacts, one bone needle, broken just at the eye, was unearthed; also a polished antler of a deer (*Cervus elaphus*), of which the surface is scratched all over and highly polished; it resembles the *bâton de commandement* but is without the perforation.

Of ornamental objects, the most important and characteristic are the beads, made of calcareous limestone, at present undetermined. One face is caused by grinding, and on the other side a hole has been made by drilling to complete the perforation; the part not reached by drilling has been struck off. The seven beads collected have all been painted red with hæmatite. They were found near one of the female skulls.

Four bone pendants were collected. They are made, apparently, of the bones of big birds, and are highly polished and hollow inside. On the surfaces of all are transverse grooves, at present not understood. A perforated pebble is of some igneous rock. It is water-rolled, but one surface seems to have been ground to a certain extent. The perforation was made by drilling from two sides. The perforated marine shells belong to a species of Arca now found plentifully along the China coast. A large hole has been made near the beak of each shell by rubbing. The margin is also rubbed. The supra orbital bone of a very large fish, possibly more than three feet long, of the carp family, has a small perforation made from each side of the bone. It is a unique find on an Upper Palæolithic site, whether in China or in Europe. All these evidently were elements of a necklace. Vertebræ of fish found in association with archæological objects, though showing no trace of human handiwork, may also have been used as a necklace or ornament, as they have a natural perforation.

The most abundant and characteristic objects, however, are the canines of deer or small carnivores, with perforations. Of these, 125 have been found, among them some tens being painted red. The perforation was made by scratching from both sides, not by drilling. Often they were found in series, and obviously represent parts of necklaces or other ornament.

Working techniques. These comprise polishing, grinding, drilling, scratching, rubbing, and colouring. In reference to this last, pieces of hæmatite have been found showing traces of scratching.

Culture : (1) *Burial customs.* The Upper Cave was evidently a burial cave in which the remains were disturbed by animals. Of the mode of burial nothing is known beyond the fact that a quantity of hæmatite powder was scattered around the dead.

(2) *Communications.* Upper Palæolithic man of Choukoutien had relations over a wide area extending 150 kilometres to the north, 350 kilometres to the south and 200 kilometres to the south-east. The indications are marine shells from a sea-coast, of which the nearest point is now 200 km. to the south-east; hæmatite, large-grained and oolitic in structure, iron ore of this nature being known only in the district of Lungkuan, about 150 km. to the north, with high mountain ranges intervening; the big linocoid shell found at the present day only on the south bank of the Yellow River, 350 km. or more to the south.

(3) *Clothing.* The suggestion of the bone needle is the sewing of cloth, while perforated objects point to the passing of string for a necklace ornament. The inference is that some type of clothing with ornaments was in use.

(4) *Other elements.* Though of the daily life nothing is known, pieces of charcoal and layers of ashes full of free carbon imply the use of fire, while fish vertebræ point to the practice of fishing, though no harpoon or hook has been found. The presence of teeth of deer, fox, badger, and pendants of the bones of a big bird suggest that these animals may have been hunted.

Comparison with Europe. As there is no material in China for comparison, no chronological succession can be established. Geologically, the culture is contemporary with the Grand Loess of North China, that is, late Pleistocene, and as such comparable with the Upper Palæolithic of Europe. The technique of scratching instead of drilling in perforation is more primitive than either Magdalenian or Aurignacian; but at the same time, the technique of fashioning beads, the grinding, drilling, polishing, show that the culture could scarcely be more primitive than Magdalenian. Hence, though geologically contemporary with either of these cultures, the cultural relation remains an open question.

THE VICTORIA FALLS HYDRO-ELECTRIC SCHEME

THE Victoria Falls and Transvaal Power Company has recently completed a very successful hydro-electric scheme at the Victoria Falls on the Zambezi River. About thirty years ago a proposal for supplying the Rand with power from the Victoria Falls was projected. The overhead transmission line was to be 700 miles long and the pressure 150,000 volts. Although owing to technical difficulties this project could not be realized at that time, yet the Power Company retained its right to develop the power at the Falls, so that if methods of transmission were improved and developed it might become commercially feasible at a later date. The scheme that has just been completed is the first outcome of that arrangement. It is especially interesting owing to the fact that it is completely automatic.

An article by Mr. H. L. Bazalgette giving a full description of the station is published in the October–December issue of the *English Electric Journal*, the contractors being the English Electric Co., London. The generating station is situated in the third gorge, known as the 'Silent Pool', at a hairpin bend in the river about two miles downstream from the Falls. It contains two 1,000 kilowatt, automatically controlled units, the purpose of which is to generate power for transmission over a distance of about seven miles to the town of Livingstone, until recently the capital of Northern Rhodesia, and also over a distance of about two miles to the Falls Hotel which, with the generating station itself, is in Southern Rhodesia.

In 1936 a comprehensive contract was placed with the English Electric Company for the power station and substation equipment. On March 17, 1938, the new power station was opened by the Governor of Northern Rhodesia, who by simply pressing a button started up the first unit under automatic control. In addition to the two purposes mentioned above, the plant will be able to supply any small industries arising around the town of Livingstone, which may eventually become the centre of an active industrial area.

The climatic conditions are damp and tropical and were exceptionally trying for the erecting staff, the engine room temperature rising at times to 110° F. Owing to the fact that the site is a famous beauty spot, great care was taken by the Power Company in South Africa to obviate disfigurement, and this has been done so successfully that the power station and penstock are practically hidden by vegetation from passers-by. Beyond a daily visit of inspection, the station runs automatically and is unattended. From the point of view of health the situation of the station would be unsuitable for the prolonged attendance of an operating staff.

Automatic devices are introduced which give protection from sustained over-current, over-voltage, over-speed, alternator field failure, internal faults, overheated bearings, oil failure and if it takes longer than the normal starting time. Any of these would automatically cause the unit to shut down and the main oil switch to 'trip'.

The erection and placing into service of the plant was carried out by C. G. T. Clarke, who spent fifteen months on the site. A very interesting and scientific account of the Victoria Falls, written by him, is quoted in the *Journal*. It was carried out in co-operation with the Survey Department of the Northern Rhodesia Government. Between the Main Falls and the Devil's Cataract there exists a small valley hitherto unseen by man which presents a splendid spectacle of beauty with its carpet of maidenhair fern and overhung by evergreen trees. The spray from Devil's Cataract there serves the glade as a natural water-can, and the water drops sparkle in the brilliant sunshine which penetrates the trees. At the bottom of the Devil's Cataract the great pool is always kept in a very turbulent state by the ever-falling torrent, creating waves at least two feet high on the far side of the pool, while the spray rises far above the precipitous sides and produces brilliant rainbows by day or by night at full moon. The wedge-shaped crevice cutting into Cataract Island gives clear evidence of earthquake activity and could not have been caused by erosion of the hard basalt rock. By descending hand over hand by means of a rope attached to a tree on the crest of the Falls on the Eastern Cataract, Mr. Clarke and his assistant got to the bottom of the abyss.

They observed that at the base of the Falls chasm the strata are vertical and run parallel to the Falls, yet the 300 ft. of basalt comprising the perpendicular face of the Falls appears to be in five distinct layers in the horizontal plane, each layer being a shade different in colour. They swam across the pool beyond the base of the Eastern Cataract after convincing themselves that no crocodiles were present. They explored the entire base of the Falls for the first time and state definitely that no traces of animal remains were seen.

With the help of the chief surveyor, Mr. Younger, twelve careful readings of the height of the Falls were taken. The maximum height was found to be 355 ft., and this spot is at a place on the west side of the "Arm Chair". Devil's Cataract has a drop of 200 ft., while the Eastern Cataract is 282 ft. high.

ELECTRICALLY MANUFACTURED STEELS

A PAPER on electrically manufactured steels by H. B. Sieveking, of the Central Electricity Board, originally allocated for reading before the Institution of Electrical Engineers on November 23, has been circulated owing to the decision not to hold meetings for the time being. He first gives a description of the two principal types of electric furnaces used; the main products are next discussed from a metallurgical point of view and the advantages and disadvantages of the two types of furnaces for meeting specific requirements are reviewed.

For the manufacture of steel two types of furnace have been developed—the arc and the high-frequency induction types. The low-frequency type is rarely used nowadays. Arc furnaces are used for melting or for keeping molten metal hot. Generally they are of the vertical 3-phase 3-electrode type. The furnace comprises a refractory hearth which may be of 'basic' (for example, magnesite, MgO) or 'acid' (for example, silica SiO_2) material as required and in which the charge is placed. The necessary heat is obtained by electric arcs formed between the charge and the electrodes which project through the roof in triangular formation. In general, an acid lining is cheaper but this type of lining is 'dead', that is, it does not allow of impurities being removed from the bath. The more expensive basic lining, on the other hand, is suitable for refining. The position of the electrodes is adjusted either by hand or automatically. Hand adjustment is simple but is apt to give rise to violent fluctuations of power. Some form of automatic control, consisting of an electric motor, or a hydraulic servo motor on each electrode, is to be preferred. A special transformer is used with special tappings which allow of a voltage variation from 60 to 250 during service. The largest size in practice will usually take a charge of about 30 tons. There is one in use in America which has six arcs and will take a charge of 100 tons.

There exist to-day a very large number of alloy steels, some of which present manufacturing difficulties which can only be overcome in an electric furnace. Let us first consider the high-frequency furnace. It has very thin walls but it is possible to get through about fifty charges without relining. This corresponds to about one week's working. The advantages of this type of furnace are: the absence of oxidizing atmosphere, no carbon pick-up, suitability for intermittent operation and high temperatures are obtainable. The disadvantages are its high capital cost and limited capacity. It is known that an arc furnace load is such that with a good operating power factor the short-circuit current swings to be taken on the mains will not exceed twice full load. The swings usually occur in the first half of the melting period. In Great Britain until 1934 the proportion of electric steel was nearly constant, with two well-marked exceptions in 1918 and 1926—the last year of the War and the year of the General Strike respectively. Since 1934, which corresponds to a period first of trade depression and then of rearmament, there has been a steady increase in the proportion.

In the United States the electric steel follows very closely the total output of steel. The United States, Germany and Great Britain stand respectively first, second and third in regard to total output, but sixth, eighth and ninth in respect of proportion of electric steel produced, being above only Luxembourg and Belgium. The countries producing the greatest proportion of steel electrically are Italy and Sweden—countries rich in water power and poor in coal, and only standing seventh and eleventh in regard to total output. The world output of electric steel is about 3 per cent of the total, but if Italy and Sweden are omitted the proportion is only 2 per cent. From the tables given in the paper it is evident that in Great Britain the term electric steel must be confined at present to steels which have a high selling price. The weight of finished steel used to-day is far higher than that required in theory as engineers use a high factor of safety. With ordinary steel the material structure is not uniform and therefore the strength of the weakest point must be guessed and the steel dimensioned accordingly. An electric steel, on the other hand, has a very uniform structure and it would therefore seem possible to reduce the factor of safety at least by an amount sufficient to make the total cost of the steel requirements the same whether the steel is manufactured electrically or by one of the other methods. It is undoubtedly along these lines that some countries are working at the present time in order to reduce their internal steel consumption to a minimum.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

Teacher of Electrical Engineering—The Principal, County Mining and Technical School, Nuneaton, Warwickshire (January 8).

Experimental Officers (male or female) in the Chemical Inspection Department, Woolwich, or at Provincial Stations in Great Britain—The Ministry of Supply (S.E. 3.B), The Adelphi, W.C.2 (quoting Appts. 016/S.E.3(B)) (January 4).

A Master for Physics and Mathematics—P. Abson, Haberdashers' Aske's School, Chase Lodge, N.W.7.

Temporary Meteorological Assistants (male) in the Meteorological Office—The Under-Secretary of State, S.2.B.(Met.), Department Q.J., Air Ministry, Adastral House, Kingsway, W.C.2.

A Part-time Teacher of Engineering Drawing—The Director of Education, The Polytechnic, 309 Regent Street, W.1.
